ARM® Architecture Reference Manual

ARMv8, for ARMv8-A architecture profile

Beta

ARM®

ARM DDI 0487A.b (ID122413)

ARM Architecture Reference Manual
ARMv8, for ARMv8-A architecture profile

Release Information

The following releases of this document have been made.

Release history

Date	Issue	Confidentiality	Change
30 April 2013	A.a-1	Confidential-Beta Draft	Beta draft of first issue, limited circulation
12 June 2013	A.a-2	Confidential-Beta Draft	Second beta draft of first issue, limited circulation
04 Septenber 2013	A.a	Non-Confidential Beta	Beta release.
24 December 2013	A.b	Non-Confidential Beta	Second Beta release.

Proprietary Notice

LES-PRE-20327

In this document, where the term ARM is used to refer to the company it means “ARM or any of its subsidiaries as appropriate”.

Note

- The term ARM can refer to versions of the ARM architecture, for example ARMv7 refers to version 7 of the ARM architecture. The context makes it clear when the term is used in this way.
- This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

ARM Architecture Reference Manual ARMv8, for ARMv8-A architecture profile

Part F The AArch32 Instruction Sets

Preface

This preface introduces the *ARM Architecture Reference Manual, ARMv8, for ARMv8-A architecture profile*. It contains the following sections:

Note

This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition.*

About this manual

This manual describes the ARM® architecture v8, ARMv8. The architecture describes the operation of an ARMv8-A *Processing element (PE)*, and this manual includes descriptions of:

- The two Execution states, AArch64 and AArch32.
- The instruction sets:
  - In AArch32 state, the A32 and T32 instruction sets, that are compatible with earlier versions of the ARM architecture.
  - In AArch64 state, the A64 instruction set.
- The states that determine how a PE operates, including the current Exception level and Security state, and in AArch32 state the PE mode.
- The Exception model.
- The interprocessing model, that supports transitioning between AArch64 state and AArch32 state.
- The memory model, that defines memory ordering and memory management. This manual covers a single architecture profile, ARMv8-A, that defines a *Virtual Memory System Architecture* (VMSA).
- The programmers' model, and its interfaces to System registers that control most PE and memory system features, and provide status information.
- The Advanced SIMD and floating-point instructions, that provide high-performance:
  - Single-precision and double-precision floating-point operations
  - Conversions between double-precision, single-precision, and half-precision floating-point values.
  - Integer, single-precision floating-point, and in A64, double-precision vector operations in all instruction sets.
  - Double-precision floating-point vector operations in the A64 instruction set.
- The security model, that provides two security states to support secure applications.
- The virtualization model, that support the virtualization of Non-secure operation.
- The Debug architecture, that provides software access to debug features.

This manual gives the assembler syntax for the instructions it describes, meaning that it describes instructions in textual form. However, this manual is not a tutorial for ARM assembler language, nor does it describe ARM assembler language, except at a very basic level. To make effective use of ARM assembler language, read the documentation supplied with the assembler being used.

This manual is organized into parts:

Part A Provides an introduction to the ARMv8-A architecture, and an overview of the AArch64 and AArch32 Execution states.

Part B Describes the application level view of the AArch64 Execution state, meaning the view from EL0. It describes the application level view of the programmers' model and the memory model.

Part C Describes the A64 instruction set, that is available in the AArch64 Execution state. The descriptions for each instruction also include the precise effects of each instruction when executed at EL0, described as *unprivileged* execution, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

Part D Describes the system level view of the AArch64 Execution state. It includes details of the System registers, most of which are not accessible from EL0, and the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug in AArch64 state.

Part E Describes the application level view of the AArch32 Execution state, meaning the view from the EL0. It describes the application level view of the programmers' model and the memory model.

Note

In AArch32 state, execution at EL0 is execution in User mode.

Part F Describes the T32 and A32 instruction sets, that are available in the AArch32 Execution state. These instruction sets are backwards-compatible with earlier versions of the ARM architecture. This part describes the precise effects of each instruction when executed in User mode, described as *unprivileged* execution or execution at EL0, including any restrictions on its use, and how the effects of the instruction differ at higher Exception levels. This information is of primary importance to authors and users of compilers, assemblers, and other programs that generate ARM machine code.

Note

User mode is the only mode where software execution is unprivileged.

Part G Describes the system level view of the AArch32 Execution state, that is generally compatible with earlier versions of the ARM architecture. This part includes details of the System registers, most of which are not accessible from EL0, and the conceptual coprocessor interface to those registers. It also describes the system level view of the programmers' model and the memory model. This part includes the description of self-hosted debug in AArch32 state.

Part H Describes the Debug architecture for external debug. This provides configuration, breakpoint and watchpoint support, and a *Debug Communications Channel* (DCC) to a debug host.

Part I Describes additional features of the architecture that are not closely coupled to a *processing element* (PE), and therefore are accessed through memory-mapped interfaces. Some of these features are OPTIONAL.

Appendixes Provide additional information that is not part of the ARMv8 architectural requirements.

Using this manual

The information in this manual is organized into parts, as described in this section.

Part A, Introduction and Architecture Overview

Part A gives an overview of the ARMv8-A architecture profile, including its relationship to the other ARM PE architectures. It introduces the terminology used to describe the architecture, and gives an overview of the Executions states, AArch64 and AArch32. It contains the following chapter:

Chapter A1 *Introduction to the ARMv8 Architecture*

Read this for an introduction to the ARMv8 architecture.

Part B, The AArch64 Application Level Architecture

Part B describes the application level view of the architecture in AArch64 state. It contains the following chapters:

Chapter B1 *The AArch64 Application Level Programmers' Model*

Read this for an application level description of the programmers' model for software executing in AArch64 state. It describes execution at EL0 when EL0 is using AArch64 state.

Chapter B2 *The AArch64 Application Level Memory Model*

Read this for an application level description of the memory model for software executing in AArch64 state. It describes the memory model for execution in EL0 when EL0 is using AArch64 state. It includes information about ARM memory types, attributes, and memory access controls.

Part C, The A64 Instruction Set

Part C describes the A64 instruction set, that is used in AArch64 state. It contains the following chapters:

Chapter C1 *The A64 Instruction Set*

Read this for a description of the A64 instruction set and common instruction operation details.

Chapter C2 *About the A64 Instruction Descriptions*

Read this for a description of the A64 instruction descriptions.

Chapter C3 *A64 Instruction Set Overview*

Read this for an overview of the individual A64 instructions, that are divided into five functional groups.

Chapter C4 *A64 Instruction Set Encoding*

Read this for a description of the A64 instruction set encoding.

Chapter C5 *The A64 System Instruction Class*

Read this for a description of the AArch64 system instructions and register descriptions, and the system instruction class encoding space.

Chapter C6 *A64 Base Instruction Descriptions*

Read this for information on key aspects of the A64 base instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*

Read this for information on key aspects of the A64 Advanced SIMD and floating-point instructions and for descriptions of the individual instructions, which are listed in alphabetical order.

Part D, The AArch64 System Level Architecture

Part D describes the AArch64 the system level view of the architecture. It contains the following chapters:

Chapter D1 *The AArch64 System Level Programmers' Model*

Read this for a description of the AArch64 system level view of the programmers' model.

Chapter D2 *AArch64 Self-hosted Debug*

Read this for an introduction to, and a description of, self-hosted debug in AArch64 state.

Chapter D3 *The AArch64 System Level Memory Model*

Read this for a description of the AArch64 system level view of the general features of the memory system.

Chapter D4 *The AArch64 Virtual Memory System Architecture*

Read this for a system level view of the AArch64 Virtual Memory System Architecture (VMSA), the memory system architecture of an ARMv8 implementation that is executing in AArch64 state.

Chapter D5 *The Performance Monitors Extension*

Read this for a description of an implementation of the ARM Performance Monitors, that are an optional non-invasive debug component.

Chapter D6 *The Generic Timer*

Read this for a description of an implementation of the ARM Generic Timer, that is an optional extension to an ARMv8 implementation.

Chapter D7 *AArch64 System Register Descriptions*

Read this for an introduction to, and description of, each of the AArch64 system registers.

Part E, The AArch32 Application Level Architecture

Part E describes the AArch32 application level view of the architecture. It contains the following chapters:

Chapter E1 *The AArch32 Application Level Programmers' Model*

Read this for an application level description of the programmers' model for software executing in AArch32 state. It describes execution at EL0 when EL0 is using AArch32 state.

Chapter E2 *The AArch32 Application Level Memory Model*

Read this for an application level description of the memory model for software executing in AArch32 state. It describes the memory model for execution in EL0 when EL0 is using AArch32 state. It includes information about ARM memory types, attributes, and memory access controls.

Part F, The AArch32 Instruction Sets

Part F describes the T32 and A32 instruction sets, that are used in AArch32 state. It contains the following chapters:

Chapter F1 *The AArch32 Instruction Sets Overview*

Read this for an overview of the T32 and A32 instruction sets.

Chapter F2 *About the T32 and A32 Instruction Descriptions*

Read this for a description of the T32 and A32 instructions.

Chapter F3 *T32 Base Instruction Set Encoding*

Read this for an introduction to the T32 instruction set and a description of how the T32 instruction set uses the ARM programmers' model.

Chapter F4 *A32 Base Instruction Set Encoding*

Read this for a description of the A32 base instruction set encoding.

Chapter F5 ***T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings***

Read this for an overview of the T32 and A32 Advanced SIMD and floating-point instruction sets.

Chapter F6 ***ARMv8 Changes to the T32 and A32 Instruction Sets***

Read this for a summary of the changes that are introduced to the T32 and A32 instruction sets in ARMv8.

Chapter F7 ***T32 and A32 Base Instruction Set Instruction Descriptions***

Read this for a description of each T32 and A32 base instruction.

Chapter F8 ***T32 and A32 Advanced SIMD and floating-point Instruction Descriptions***

Read this for a description of each T32 and A32 Advanced SIMD and floating-point instruction.

Part G, The AArch32 System Level Architecture

Part G describes the AArch32 system level view of the architecture. It contains the following chapters:

Chapter G1 ***The AArch32 System Level Programmers' Model***

Read this for a description of the AArch32 system level view of the programmers' model for execution in an Exception level that is using AArch32.

Chapter G2 ***AArch32 Self-hosted Debug***

Read this for an introduction to, and a description of, self-hosted debug in AArch32 state.

Chapter G3 ***The AArch32 System Level Memory Model***

Read this for a system level view of the general features of the memory system.

Chapter G4 ***The AArch32 Virtual Memory System Architecture***

Read this for a description of the AArch32 Virtual Memory System Architecture (VMSA).

Chapter G5 ***AArch32 System Register Descriptions***

Read this for a description of each of the AArch32 system registers.

Part H, External Debug

Part H describes the architecture for external debug. It contains the following chapters:

Chapter H1 ***Introduction to External Debug***

Read this for an introduction to external debug, and a definition of the scope of this part of the manual.

Chapter H2 ***Debug State***

Read this for a description of debug state, which the PE might enter as the result of a Halting debug event.

Chapter H3 ***Halting Debug Events***

Read this for a description of the external debug events referred to as Halting debug events.

Chapter H4 ***The Debug Communication Channel and Instruction Transfer Register***

Read this for a description of the communication between a debugger and the PE debug logic using the Debug Communications Channel and the Instruction Transfer register.

Chapter H5 ***The Embedded Cross Trigger Interface***

Read this for a description of the embedded cross-trigger interface.

Chapter H6 ***Debug Reset and Powerdown Support***

Read this for a description of reset and powerdown support in the Debug architecture.

Chapter H7 *The Sample-based Profiling Extension*

Read this for a description of the Sample-based Profiling Extension that is an OPTIONAL extension to an ARMv8 implementation.

Chapter H8 *About the External Debug Registers*

Read this for some additional information about the external debug registers.

Chapter H9 *External Debug Register Descriptions*

Read this for a description of each external debug register.

Part I, Memory-mapped Components of the ARMv8 Architecture

Part I describes the memory-mapped components in the architecture. It contains the following chapters:

Chapter I1 *System Level Implementation of the Generic Timer*

Read this for a definition of a system level implementation of the Generic Timer.

Chapter I2 *Recommended Memory-mapped Interfaces to the Performance Monitors*

Read this for a description of the recommended memory-mapped and external debug interfaces to the Performance Monitors.

Chapter I3 *Memory-Mapped System Register Descriptions*

Read this for a description of each memory-mapped system register.

Part J, Appendixes

This manual contains the following appendixes:

Appendix A *Architectural Constraints on UNPREDICTABLE behaviors*

Read this for a description of the architecturally-required constraints on UNPREDICTABLE behaviors in the ARMv8 architecture, including AArch32 behaviors that were UNPREDICTABLE in previous versions of the architecture.

Appendix B *Recommended External Debug Interface*

Read this for a description of the recommended external debug interface.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix C *Recommendations for Performance Monitors Event Numbers for IMPLEMENTATION DEFINED Events*

Read this for a description of ARM recommendations for the use of the IMPLEMENTATION DEFINED event numbers.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix D *Example OS Save and Restore sequences*

Read this for software examples that perform the OS Save and Restore sequences for an ARMv8 debug implementation.

Note

Chapter H6 *Debug Reset and Powerdown Support* describes the OS Save and Restore mechanism.

Appendix E *Recommended Upload and Download Processes for External Debug*

Read this for information about implementing and using the ARM architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix F *Barrier Litmus Tests*

Read this for examples of the use of barrier instructions provided by the ARMv8 architecture.

Note

This description is not part of the ARM architecture specification. It is included here as supplementary information, for the convenience of developers and users who might require this information.

Appendix G *ARMv8 Pseudocode Library*

Read this for this for all the ARMv8-A pseudocode definitions.

Appendix H *ARM Pseudocode Definition*

Read this for definitions of the AArch32 pseudocode.

Appendix I *Pseudocode Index*

Read this for an index of the pseudocode.

Appendix J *Registers Index*

Read this for an alphabetic and functional index of AArch32 and AArch64 registers, and memory-mapped registers.

Conventions

The following sections describe conventions that this book can use:

- *Typographic conventions*.
- *Signals*.
- *Numbers*.
- *Pseudocode descriptions*.
- *Assembler syntax descriptions* on page xxiv.

Typographic conventions

The typographical conventions are:

italic Introduces special terminology, and denotes citations.

bold Denotes signal names, and is used for terms in descriptive lists, where appropriate.

`monospace` Used for assembler syntax descriptions, pseudocode, and source code examples.

Also used in the main text for instruction mnemonics and for references to other items appearing in assembler syntax descriptions, pseudocode, and source code examples.

SMALL CAPITALS

Used in body text for a few terms that have specific technical meanings, and are defined in the *Glossary*.

Colored text Indicates a link. This can be:

- A URL, for example, `http://infocenter.arm.com`.
- A cross-reference, that includes the page number of the referenced information if it is not on the current page, for example, *Pseudocode descriptions*.
- A link, to a chapter or appendix, or to a glossary entry, or to the section of the document that defines the colored term, for example *Simple sequential execution* or SCTLR.

Signals

In general this specification does not define hardware signals, but it does include some signal examples and recommendations. The signal conventions are:

Signal level The level of an asserted signal depends on whether the signal is active-HIGH or active-LOW. Asserted means:

- HIGH for active-HIGH signals.
- LOW for active-LOW signals.

Lower-case n At the start or end of a signal name denotes an active-LOW signal.

Numbers

Numbers are normally written in decimal. Binary numbers are preceded by `0b`, and hexadecimal numbers by `0x`. In both cases, the prefix and the associated value are written in a `monospace` font, for example `0xFFFF0000`. To improve readability, long numbers can be written with an underscore separator between every four characters, for example `0xFFFF_0000_0000_0000`. Ignore any underscores when interpreting the value of a number.

Pseudocode descriptions

This manual uses a form of pseudocode to provide precise descriptions of the specified functionality. This pseudocode is written in `monospace` font, and is described in Appendix H *ARM Pseudocode Definition*.

Assembler syntax descriptions

This manual contains numerous syntax descriptions for assembler instructions and for components of assembler instructions. These are shown in a `monospace` font, and use the conventions described in *Structure of the A64 assembler language* on page C1-111, Appendix H *ARM Pseudocode Definition*, and *Pseudocode operators and keywords* on page AppxI-5158.

Additional reading

This section lists relevant publications from ARM and third parties.

See the Infocenter, http://infocenter.arm.com, for access to ARM documentation.

ARM publications

- *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition* (ARM DDI 0406).
- *ARM Debug Interface Architecture Specification, ADIv5.0 to ADIv5.2* (ARM IHI 0031).
- *CoreSight Program Flow Trace Architecture Specification* (ARM IHI 0035).
- *ARM®Embedded Trace Macrocell Architecture Specification, ETMv4* (ARM IHI 0064).
- *ARM Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0* (ARM IHI 0048).
- *CoreSight™ SoC Technical Reference Manual* (ARM DDI 0480).
- *ARM Procedure Call Standard for the ARM 64-bit Architecture* (ARM IHI 0055).

Other publications

The following publications are referred to in this manual, or provide more information:

- *Announcing the Advanced Encryption Standard (AES)*, Federal Information Processing Standards Publication 197, November 2001.
- IEEE 754-2008, *IEEE Standard for Floating-point Arithmetic*, August 2008.
- *Secure Hash Standard (SHA)*, Federal Information Processing Standards Publication 180-2, August 2002.
- *The Galois/Counter Mode of Operation*, McGraw, D. and Viega, J., Submission to NIST Modes of Operation Process, January 2004.
- *Memory Consistency Models for Shared Memory-Multiprocessors*, Gharachorloo, Kourosh, 1995, Stanford University Technical Report CSL-TR-95-685.

Feedback

ARM welcomes feedback on its documentation.

Feedback on this manual

If you have comments on the content of this manual, send e-mail to `errata@arm.com`. Give:

- The title.
- The number, ARM DDI 0487A.b.
- The page numbers to which your comments apply.
- A concise explanation of your comments.

ARM also welcomes general suggestions for additions and improvements.

Part A

ARMv8 Architecture Introduction and Overview

Chapter A1
Introduction to the ARMv8 Architecture

This chapter introduces the ARM architecture and contains the following sections:

A1.1 About the ARM architecture

The ARM architecture-described in this Architecture Reference Manual defines the behavior of an abstract machine, referred to as a *Processing Element*, often abbreviated to *PE*. Implementations compliant with the ARM architecture must conform to the described behavior of the Processing Element. It is not intended to describe how to build an implementation of the PE, nor to limit the scope of such implementations beyond the defined behaviors.

Except where the architecture specifies differently, the programmer-visible behavior of an implementation that is compliant with the ARM architecture must be the same as a simple sequential execution of the program on the processing element. This programmer-visible behavior does not include the execution time of the program.

The ARM Architecture Reference Manual also describes rules for software to use the Processing Element.

The ARM architecture includes definitions of:

- An associated debug architecture, see:
  - Chapter D2 *AArch64 Self-hosted Debug*.
  - Chapter G2 *AArch32 Self-hosted Debug*.
  - Part H of this manual, *External Debug* on page 4387.
- Associated trace architectures, that define trace macrocells that implementers can implement with the associated processor hardware. For more information see the *Embedded Trace Macrocell Architecture Specification* and the *CoreSight Program Flow Trace Architecture Specification.*

The ARM architecture is a *Reduced Instruction Set Computer* (RISC) architecture with the following RISC architecture features:

- A large uniform register file.
- A *load/store* architecture, where data-processing operations only operate on register contents, not directly on memory contents.
- Simple addressing modes, with all load/store addresses determined from register contents and instruction fields only.

The architecture defines the interaction of the Processing Element with memory, including caches, and includes a memory translation system. It also describes how multiple Processing Elements interact with each other and with other observers in a system.

This document defines the ARMv8-A architecture *profile*. See *Architecture profiles* on page A1-32 for more information.

The ARM architecture supports implementations across a wide range of performance points. Implementation size, performance, and very low power consumption are key attributes of the ARM architecture.

An important feature of the ARMv8 architecture is backwards compatibility, combined with the freedom for optimal implementation in a wide range of standard and more specialized use cases. The ARMv8 architecture supports:

- A 64-bit Execution state, AArch64.
- A 32-bit Execution state, AArch32, that is compatible with previous versions of the ARM architecture.

Note

- The AArch32 Execution state is compatible with the ARMv7-A architecture profile, and enhances that profile to support some features included in the AArch64 Execution state.
- This document describes only the ARMv8-A architecture profile. For the behaviors required by the ARMv7-A and ARMv7-R architecture profiles, see the *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.

Both Execution states support SIMD and floating-point instructions:

- AArch32 state provides:
  - SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers.
  - Advanced SIMD instructions that operate on registers in the SIMD and floating-point register file.
  - Floating-point instructions that operate on registers in the SIMD and floating-point register file.
- AArch64 state provides:
  - Advanced SIMD instructions that operate on registers in the SIMD and floating-point register file.
  - Floating-point instructions that operate on registers in the SIMD and floating-point register file.

Note

See *Conventions* on page xxiii for information about conventions used in this manual, including the use of SMALL CAPITALS for the terms CONSTRAINED UNPREDICTABLE, IMPLEMENTATION DEFINED, OPTIONAL, RES0, RES1, UNDEFINED, UNKNOWN, and UNPREDICTABLE, that have ARM-specific meanings that are defined in the *Glossary*.

A1.2 Architecture profiles

The ARM architecture has evolved significantly since its introduction, and ARM continues to develop it. Eight major versions of the architecture have been defined to date, denoted by the version numbers 1 to 8. Of these, the first three versions are now obsolete.

The generic names AArch64 and AArch32 describe the 64-bit and 32-bit Execution states:

AArch64 Is the 64-bit Execution state, meaning addresses are held in 64-bit registers, and instructions in the base instruction set can use 64-bit registers for their processing. AArch64 state supports the A64 instruction set.

AArch32 Is the 32-bit Execution state, meaning addresses are held in 32-bit registers, and instructions in the base instruction sets use 32-bit registers for their processing. AArch32 state supports the T32 and A32 instruction sets.

Note

The *Base instruction set* comprises the supported instructions other than the Advanced SIMD and floating-point instructions.

See sections *Execution state* on page A1-33 and *The ARM instruction sets* on page A1-34 for more information.

ARM defines three architecture profiles:

A Application profile, described in this manual:

- Supports a *Virtual Memory System Architecture* (VMSA) based on a *Memory Management Unit* (MMU).

  Note

  An ARMv8-A implementation can be called an AArchv8-A implementation.

- Supports the A64, A32, and T32 instruction sets.

R Real-time profile:

- Supports a *Protected Memory System Architecture* (PMSA) based on a *Memory Protection Unit* (MPU).
- Supports the A32 and T32 instruction sets.

M Microcontroller profile:

- Implements a programmers' model designed for low-latency interrupt processing, with hardware stacking of registers and support for writing interrupt handlers in high-level languages.
- Implements a variant of the R-profile PMSA.
- Supports a variant of the T32 instruction set.

Note

This Architecture Reference Manual describes only the ARMv8-A profile.

For information about the R and M architecture profiles, and earlier ARM architecture versions see:

- The *ARM® Architecture Reference Manual, ARMv7-A and ARMv7-R edition*.
- The *ARM®v7-M Architecture Reference Manual*.
- The *ARM®v6-M Architecture Reference Manual*.

A1.2.1 Debug architecture version

The ARM debug architecture is fully integrated with the architecture, and does not have a separate version number.

A1.3 ARMv8 architectural concepts

ARMv8 introduces major changes to the ARM architecture, while maintaining a high level of consistency with previous versions of the architecture. The ARMv8 Architecture Reference Manual includes significant changes in the terminology used to describe the architecture, and this section introduces both the ARMv8 architectural concepts and the associated terminology.

The following subsections describe key ARMv8 architectural concepts. Each section introduces the corresponding terms that are used to describe the architecture:

- *Execution state*.
- *The ARM instruction sets* on page A1-34.
- *System registers* on page A1-34.
- *ARMv8 Debug* on page A1-35.

A1.3.1 Execution state

The Execution state defines the PE execution environment, including:

- The supported register widths.
- The supported instruction sets.
- Significant aspects of:
  - The exception model.
  - The *Virtual Memory System Architecture* (VMSA).
  - The programmers' model.

The Execution states are:

AArch64 The 64-bit Execution state. This Execution state:

- Provides 31 64-bit general-purpose registers, of which X30 is used as the procedure link register.
- Provides a 64-bit *program counter* (PC), *stack pointer*s (SPs), and *exception link registers* (ELRs).
- Provides 32 128-bit registers for SIMD vector and scalar floating-point support.
- Provides a single instruction set, A64. For more information, see *The ARM instruction sets* on page A1-34.
- Defines the ARMv8 Exception model, with up to four Exception levels, EL0 - EL3, that provide an *execution privilege* hierarchy, see *Exception levels* on page D1-1400.
- Provides support for 64-bit *virtual addressing*. For more information, including the limits on address ranges, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.
- Defines a number of PSTATE elements that hold PE state. The A64 instruction set includes instructions that operate directly on various PSTATE elements.
- Names each system register using a suffix that indicates the lowest Exception level at which the register can be accessed.

AArch32 The 32-bit Execution state. This Execution state:

- Provides 13 32-bit general-purpose registers, and a 32-bit PC, SP, and *link register* (LR).The LR is used as both an ELR and a procedure link register.
  Some of these registers have multiple *banked* instances for use in different PE *modes*.
- Provides a single ELR, for exception returns from Hyp mode.
- Provides 32 64-bit registers for Advanced SIMD vector and scalar floating-point support.
- Provides two instruction sets, A32 and T32. For more information, see *The ARM instruction sets* on page A1-34.
- Supports the ARMv7-A exception model, based on *PE modes*, and maps this onto the ARMv8 Exception model, that is based on the Exception levels.
- Uses 32-bit virtual addresses.

- Uses a single *Current Program State Register* (CPSR) to hold the PE state.

Later subsections give more information about the different properties of the Execution states.

Transitioning between the AArch64 and AArch32 Execution states is known as *interprocessing*.The PE can move between Execution states only on a change of Exception level, and subject to the rules given in *Interprocessing* on page D1-1512. This means different software layers, such as an application, an operating system kernel, and a hypervisor, executing at different Exception levels, can execute in different Execution states.

A1.3.2 The ARM instruction sets

In ARMv8 the possible instruction sets depend on the Execution state:

AArch64 AArch64 state supports only a single instruction set, called A64. This is a fixed-length instruction set that uses 32-bit instruction encodings.

For information on the A64 instruction set, see Chapter C3 *A64 Instruction Set Overview*.

AArch32 AArch32 state supports the following instruction sets:

A32 This is a fixed-length instruction set that uses 32-bit instruction encodings.

T32 This is a variable-length instruction set that uses both 16-bit and 32-bit instruction encodings.

In previous documentation, these instruction sets were called the ARM and Thumb instruction sets. ARMv8 extends each of these instruction sets. In AArch32 state, the Instruction set state determines the instruction set that the PE executes.

For information on the A32 and T32 instruction sets, see Chapter F1 *The AArch32 Instruction Sets Overview*.

The ARMv8 instruction sets support SIMD and scalar floating-point instructions. See *Floating-point and Advanced SIMD support* on page A1-46.

A1.3.3 System registers

System registers provide control and status information of architected features.

The System registers use a standard naming format: <register_name>.<bit_field_name> to identify specific registers as well as control and status bits within a register.

Bits can also be described by their numerical position in the form <register_name>[x:y] or the generic form bits[x:y].

In addition, in AArch64 state, most register names include the lowest Exception level that can access the register as a suffix to the register name:

- <register_name>_ELx, where x is 0, 1, 2, or 3.

For information about Exception levels, see *Exception levels* on page D1-1400.

The System registers comprise:

- General system control registers.
- Debug registers.
- Generic Timer registers.
- Optionally, Performance Monitor registers.
- Optionally, Trace registers.
- Optionally, Generic Interrupt Controller (GIC) CPU interface registers.

The *Embedded Trace Macrocell Architecture Specification, ETMv4* defines the Trace registers. This ARMv8 reference manual describes all the other System registers.

For information about the AArch64 System registers, see Chapter D7 *AArch64 System Register Descriptions*.

For information about the AArch32 System registers, see Chapter G5 *AArch32 System Register Descriptions*.

The ARM Generic Interrupt Controller CPU interface

Version 3 of the ARM Generic Interrupt Controller architecture, GICv3, defines a system register interface to the GIC CPU interface. The System register descriptions in this ARMv8 manual include these registers, see *Generic Interrupt Controller CPU interface registers* on page D7-2106.

Note

The programmers' model for earlier versions of the GIC architecture is wholly memory-mapped.

For more information about the ARM Generic Interrupt Controller, see the *ARM Generic Interrupt Controller Architecture Specification, GIC architecture version 3.0*.

A1.3.4 ARMv8 Debug

ARMv8 supports the following:

Self-hosted debug

In this model, the PE generates *debug exceptions*. Debug exceptions are part of the ARMv8 Exception model.

External debug

In this model, *debug events* cause the PE to enter *Debug state*. In Debug state the PE is controlled by an external debugger.

All ARMv8 implementations support both models. The model chosen by a particular user depends on the debug requirements during different stages of the design and development life cycle of the product. For example, external debug might be used during debugging of the hardware implementation and OS bring-up, and self-hosted debug might be used during application development.

For more information about self-hosted debug:

- In AArch64 state, see Chapter D2 *AArch64 Self-hosted Debug*.
- In AArch32 state, see Chapter G2 *AArch32 Self-hosted Debug*.

For more information about external debug, see *Part H External Debug*.

A1.4 Supported data types

The ARMv8 architecture supports the following integer data types:

Byte 8 bits.
Halfword 16 bits.
Word 32 bits.
Doubleword 64 bits.
Quadword 128 bits.

The architecture also supports the following floating-point data types:

- Half-precision, see *Half-precision floating-point formats* on page A1-40 for details.
- Single-precision, see *Single-precision floating-point format* on page A1-42 for details.
- Double-precision, see *Double-precision floating-point format* on page A1-43 for details.

It also supports:

- Fixed-point interpretation of words and doublewords. See *Fixed-point format* on page A1-44.
- Vectors, where a register holds multiple elements, each of the same data type. See *Vector formats* on page A1-37 for details.

The ARMv8 architecture provides two register files:

- A general-purpose register file.
- A SIMD and floating-point register file.

In each of these, the possible register widths depend on the Execution state.

In AArch64 state:

- A general-purpose register file contains 64-bit registers:
  - Many instructions can access these registers as 64-bit registers or as 32-bit registers, using only the bottom 32 bits.
- A SIMD and floating-point register file contains 128-bit registers:
  - The quadword integer data types only apply to the SIMD and floating-point register file.
  - The floating-point data types only apply to the SIMD and floating-point register file.
  - While the AArch64 vector registers support 128-bit vectors, the effective vector length can be 64-bits or 128-bits depending on the A64 instruction encoding used, see *Instruction Mnemonics* on page C1-111

For more information on the register files in AArch64, see *Registers in AArch64 Execution state* on page B1-59.

In AArch32 state:

- A general-purpose register file contains 32-bit registers:
  - Two 32-bit registers can support a doubleword.
  - Vector formatting is supported, see Figure A1-4 on page A1-40.
- A SIMD and floating-point register file contains 64-bit registers:
  - AArch32 state does not support quadword integer or floating-point data types.

Note

Two consecutive 64-bit registers can be used as a 128-bit register.

For more information on the register files in AArch32, see *The general-purpose registers, and the PC, in AArch32 state* on page E1-2208

A1.4.1 Vector formats

In an implementation that includes the SIMD instructions that operate on the SIMD and floating-point register file, a register can hold one or more packed elements, all of the same size and type. The combination of a register and a data type describes a vector of elements. The vector is considered to be an array of elements of the data type specified in the instruction. The number of elements in the vector is implied by the size of the data elements and the size of the register.

Vector indices are in the range 0 to (number of elements – 1). An index of 0 refers to the least significant end of the vector.

Vector formats in AArch64 state

In AArch64 state, the SIMD and floating-point registers can be referred to as V*n*, where *n* is a value from 0 to 31.

The SIMD and floating-point registers support three data formats for loads, stores and data processing operations:

- A single, scalar, element in the least significant bits of the register.
- A 64-bit vector of byte, halfword, or word elements.
- A 128-bit vector of byte, halfword, word or doubleword elements.

The element sizes are defined in Table A1-1 with the vector format described as:

- For a 128-bit vector: Vn{.2D, .4S, .8H, .16B}.
- For a 64-bit vector: Vn{.1D, .2S, .4H, .8B}.

Table A1-1 SIMD elements

Mnemonic	Size
B	8 bits
H	16 bits
S	32 bits
D	64 bits

Figure A1-1 on page A1-38 shows the SIMD vectors in AArch64 state.

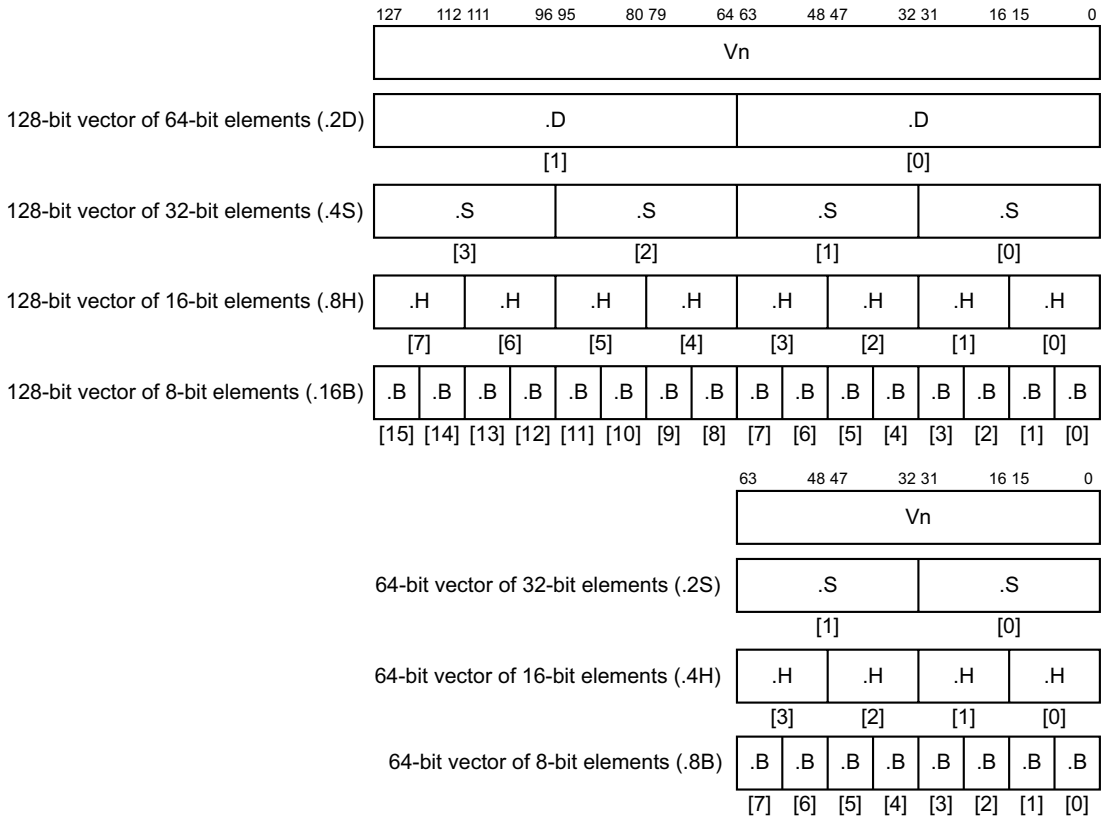

Figure A1-1 SIMD vectors in AArch64 state

Vector formats in AArch32 state

Table A1-2 shows the available formats. Each instruction description specifies the data types that the instruction supports.

Table A1-2 Advanced SIMD data types in AArch32

Data type specifier	Meaning
`.<size>`	Any element of `<size>` bits
`.F<size>`	Floating-point number of `<size>` bits
`.I<size>`	Signed or unsigned integer of `<size>` bits
`.P<size>`	Polynomial over {0, 1} of degree less than `<size>`
`.S<size>`	Signed integer of `<size>` bits
`.U<size>`	Unsigned integer of `<size>` bits

Polynomial arithmetic over {0, 1} on page A1-45 describes the polynomial data type.

The `.F16` data type is the half-precision data type selected by the FPSCR.AHP bit.

The `.F32` data type is the ARM standard single-precision floating-point data type, see *Single-precision floating-point format* on page A1-42.

The instruction definitions use a data type specifier to define the data types appropriate to the operation. Figure A1-2 on page A1-39 shows the hierarchy of the Advanced SIMD data types.

.8	.I8	.S8

† Output format only. See VMULL instruction description.

‡ Available only if the Cyptographic Extension is implemented. See VMULL instruction description.

Figure A1-2 Advanced SIMD data type hierarchy in AArch32

For example, a multiply instruction must distinguish between integer and floating-point data types.

An integer multiply instruction that generates a double-width (long) result must specify the input data types as signed or unsigned. However, some integer multiply instructions use modulo arithmetic, and therefore do not have to distinguish between signed and unsigned inputs.

Figure A1-3 on page A1-40 shows the Advanced SIMD vectors in AArch32 state.

Note

In AArch32 state, a pair of even and following odd numbered doubleword registers can be concatenated and treated as a single quadword register.

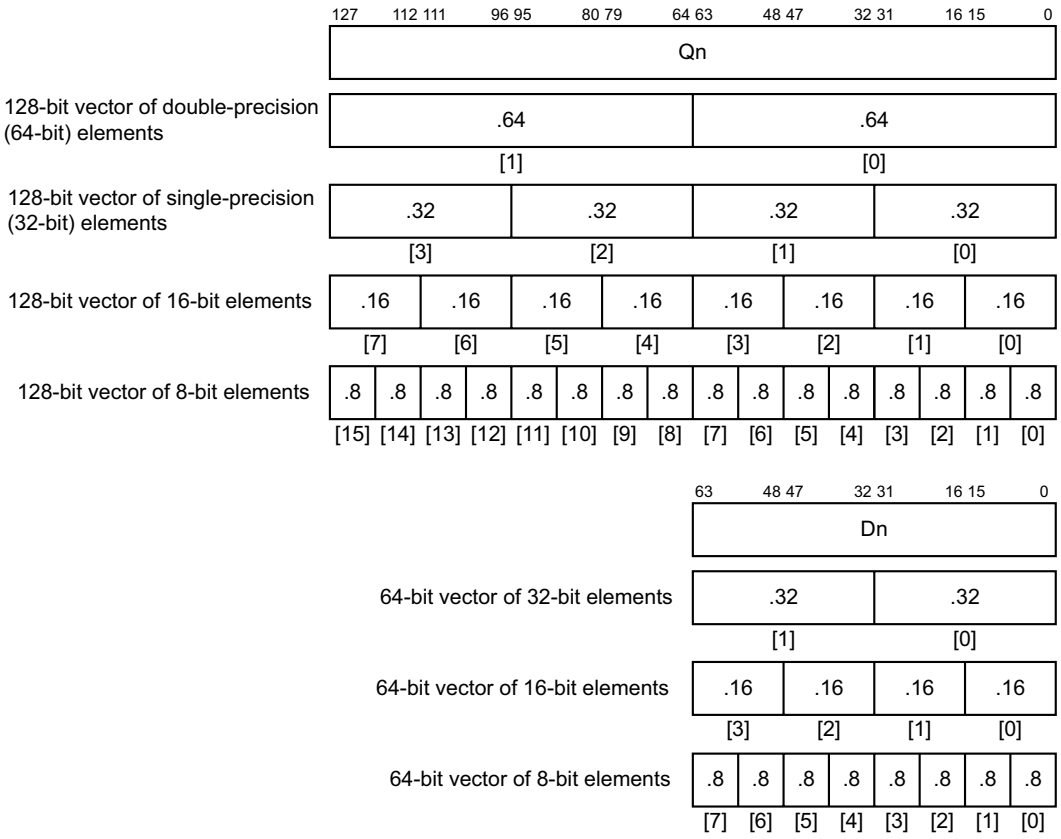

Figure A1-3 Advanced SIMD vectors in AArch32

The AArch32 general-purpose registers support vectors formats for use by the SIMD instructions in the Base instruction set. Figure A1-4 shows these formats, that means that a general-purpose register can be treated as either two halfwords or four bytes.

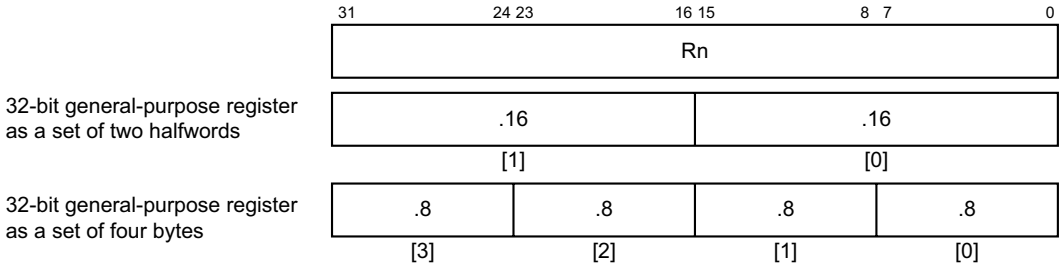

Figure A1-4 Vector formatting in AArch32

A1.4.2 Half-precision floating-point formats

ARMv8 supports two half-precision floating-point formats:

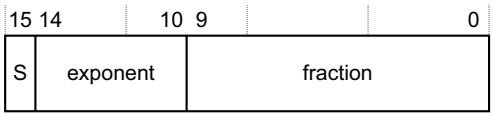
- IEEE half-precision, as described in the IEEE 754-2008 standard
- Alternative half-precision.

Note

Half-precision floating-point formats can only be converted to and from other floating-point formats. They cannot be used in any other data processing operations. This applies to both AArch32 state and AArch64 state.

The description of IEEE half-precision includes ARM-specific details that are left open by the standard, and is only an introduction to the formats and to the values they can contain. For more information, especially on the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

For both half-precision floating-point formats, the layout of the 16-bit format is the same. The format is:



The interpretation of the format depends on the value of the exponent field, bits[14:10] and on which half-precision format is being used.

0 < exponent < `0x1F`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-15)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-14}, or approximately 6.104×10^{-5}.

The maximum positive normalized number is $(2 - 2^{-10}) \times 2^{15}$, or 65504.

Larger normalized numbers can be expressed using the alternative format when the exponent == `0x1F`.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-14} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-24}, or approximately 5.960×10^{-8}.

exponent == `0x1F`

The value depends on which half-precision format is being used:

IEEE half-precision

The value is either an infinity or a Not a Number (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[9]:

bit[9] == 0 The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[9] == 1 The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

Alternative half-precision

The value is a normalized number and is equal to:

$-1^S \times 2^{16} \times (1.\text{fraction})$

The maximum positive normalized number is $(2-2^{-10}) \times 2^{16}$ or 131008.

A1.4.3 Single-precision floating-point format

The single-precision floating-point format is as defined by the IEEE 754 standard.

This description includes ARM-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

A single-precision value is a 32-bit word with the format:

The interpretation of the format depends on the value of the exponent field, bits[30:23]:

0 < exponent < `0xFF`

The value is a *normalized number* and is equal to:

$(-1)^S \times 2^{(\text{exponent} - 127)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-126}, or approximately 1.175×10^{-38}.

The maximum positive normalized number is $(2 - 2^{-23}) \times 2^{127}$, or approximately 3.403×10^{38}.

exponent == 0

The value is either a zero or a *denormalized number*, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros:

+0 When S==0.

–0 When S==1.

These usually behave identically. In particular, the result is *equal* if +0 and –0 are compared as floating-point numbers. However, they yield different results in some circumstances. For example, the sign of the infinity produced as the result of dividing by zero depends on the sign of the zero. The two zeros can be distinguished from each other by performing an integer comparison of the two words.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-126} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-149}, or approximately 1.401×10^{-45}.

Denormalized numbers are always flushed to zero in AArch32 Advanced SIMD processing. They are optionally flushed to zero in floating-point processing and AArch64 SIMD. For details see *Flush-to-zero* on page A1-49.

exponent == `0xFF`

The value is either an *infinity* or a *Not a Number* (NaN), depending on the fraction bits:

fraction == 0

The value is an infinity. There are two distinct infinities:

+infinity When S==0. This represents all positive numbers that are too big to be represented accurately as a normalized number.

-infinity When S==1. This represents all negative numbers with an absolute value that is too big to be represented accurately as a normalized number.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[22]:

bit[22] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[22] == 1

The NaN is a quiet NaN. The sign bit and remaining fraction bits can take any value.

For details of the *default NaN* see *NaN handling and the Default NaN* on page A1-50.

Note

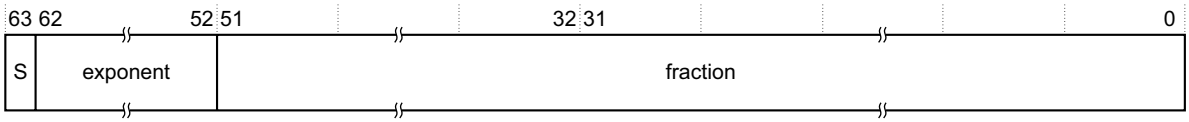
NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.4 Double-precision floating-point format

The double-precision floating-point format is as defined by the IEEE 754 standard. Double-precision floating-point is supported by both floating-point and SIMD instructions in AArch64 state, and only by floating-point instructions in AArch32 state.

This description includes implementation-specific details that are left open by the standard. It is only intended as an introduction to the formats and to the values they can contain. For full details, especially of the handling of infinities, NaNs and signed zeros, see the IEEE 754 standard.

A double-precision value is a 64-bit doubleword, with the format:



Double-precision values represent numbers, infinities and NaNs in a similar way to single-precision values, with the interpretation of the format depending on the value of the exponent:

0 < exponent < `0x7FF`

The value is a normalized number and is equal to:

$(-1)^S \times 2^{(\text{exponent}-1023)} \times (1.\text{fraction})$

The minimum positive normalized number is 2^{-1022}, or approximately 2.225×10^{-308}.

The maximum positive normalized number is $(2 - 2^{-52}) \times 2^{1023}$, or approximately 1.798×10^{308}.

exponent == 0

The value is either a zero or a denormalized number, depending on the fraction bits:

fraction == 0

The value is a zero. There are two distinct zeros that behave in the same way as the two single-precision zeros:

+0 when S==0

–0 when S==1.

fraction != 0

The value is a denormalized number and is equal to:

$(-1)^S \times 2^{-1022} \times (0.\text{fraction})$

The minimum positive denormalized number is 2^{-1074}, or approximately 4.941×10^{-324}.

Optionally, denormalized numbers are flushed to zero in floating-point calculations. For details see *Flush-to-zero* on page A1-49.

exponent == `0x7FF`

The value is either an infinity or a NaN, depending on the fraction bits:

fraction == 0

the value is an infinity. As for single-precision, there are two infinities:

+infinity When S==0.

-infinity When S==1.

fraction != 0

The value is a NaN, and is either a *quiet NaN* or a *signaling NaN*.

The two types of NaN are distinguished by their most significant fraction bit, bit[19] of the most significant word:

bit[19] == 0

The NaN is a signaling NaN. The sign bit can take any value, and the remaining fraction bits can take any value except all zeros.

bit[19] == 1

The NaN is a quiet NaN. The sign bit and the remaining fraction bits can take any value.

For details of the *default NaN* see *NaN handling and the Default NaN* on page A1-50.

Note

NaNs with different sign or fraction bits are distinct NaNs, but this does not mean software can use floating-point comparison instructions to distinguish them. This is because the IEEE 754 standard specifies that a NaN compares as *unordered* with everything, including itself.

A1.4.5 Fixed-point format

Fixed-point formats are used only for conversions between floating-point and fixed-point values. They apply to general-purpose registers.

Fixed-point values can be signed or unsigned, and can be 16-bit or 32-bit. Conversion instructions take an argument that specifies the number of fraction bits in the fixed-point number. That is, it specifies the position of the binary point.

A1.4.6 Conversion between floating-point and fixed-point values

ARMv8 supports the conversion of a scalar floating-point to or from a signed or unsigned fixed-point value in a general-purpose register.

The instruction argument #fbits indicates that the general-purpose register holds a fixed-point number with fbits bits after the binary point, where fbits is in the range 1 to 64 for a 64-bit general-purpose register, or 1 to 32 for a 32-bit general-purpose register.

More specifically:

- For a 64-bit register X_d:
  - The integer part is X_d[63:#fbits].
  - The fractional part is X_d[(#fbits-1):0].
- For a 32-bit register W_d or R_d:
  - The integer part is W_d[31:#fbits] or R_d[31:#fbits].
  - The fractional part is W_d[(#fbits-1):0] or R_d[(#fbits-1):0].

These instructions might generate the following exceptions:

Invalid Operation When the floating-point input is NaN or Infinity or when a numerical value cannot be represented within the destination register.

Inexact When the numeric result differs from the input.

Input Denormal When flush-to-zero mode is enabled and the denormal input is replaced by a zero.

Note

An out of range fixed-point result is saturated to the destination size.

A1.4.7 Polynomial arithmetic over {0, 1}

Some SIMD instructions that operate on SIMD and floating-point registers can operate on polynomials over {0, 1}, see *Supported data types* on page A1-36. The polynomial data type represents a polynomial in x of the form $b_{n-1}x^{n-1} + \ldots + b_1x + b_0$ where b_k is bit[k] of the value.

The coefficients 0 and 1 are manipulated using the rules of Boolean arithmetic:

- $0 + 0 = 1 + 1 = 0$
- $0 + 1 = 1 + 0 = 1$
- $0 \times 0 = 0 \times 1 = 1 \times 0 = 0$
- $1 \times 1 = 1$.

That is:

- Adding two polynomials over {0, 1} is the same as a bitwise exclusive OR.
- Multiplying two polynomials over {0, 1} is the same as integer multiplication except that partial products are exclusive-ORed instead of being added.

A64, A32 and T32 provide instructions for performing polynomial multiplication of 8-bit values. For AArch32, see *VMUL, VMULL (integer and polynomial)* on page F8-3198. For AArch64 see *PMUL* on page C7-1088 and *PMULL, PMULL2* on page C7-1089.

The Cryptographic Extension adds the ability to perform long polynomial multiplies of 64-bit values. See *PMULL, PMULL2* on page C7-1089.

Pseudocode details of polynomial multiplication

In pseudocode, polynomial addition is described by the EOR operation on bitstrings.

Polynomial multiplication is described by the `PolynomialMult()` function:

```
// PolynomialMult()
// ================

bits(M+N) PolynomialMult(bits(M) op1, bits(N) op2)
    result = Zeros(M+N);
    extended_op2 = ZeroExtend(op2, M+N);
    for i=0 to M-1
        if op1<i> == '1' then
            result = result EOR LSL(extended_op2, i);
    return result;
```

A1.5 Floating-point and Advanced SIMD support

Note

In AArch32 state, the SIMD instructions that operate on SIMD and floating-point registers are always described as the Advanced SIMD instructions, to distinguish them from the SIMD instructions in the base instruction sets, that operate on the 32-bit general-purpose registers. The A64 instruction set does not provide any SIMD instructions that operate on the general-purpose registers, and therefore some AArch64 state descriptions use SIMD as a synonym for Advanced SIMD. Unless the context clearly indicates otherwise, this section describes the support for SIMD instructions that operate on SIMD and floating-point registers.

ARMv8 can support the following levels of support for floating-point and Advanced SIMD instructions:

- Full floating-point and SIMD support without exception trapping.
- Full floating-point and SIMD support with exception trapping.
- No floating-point or SIMD support. This option is licensed only for implementations targeting specialised markets.

  Note

  All systems that support standard operating systems with rich application environments provide hardware support for floating-point and Advanced SIMD. It is a requirement of the ARM Procedure Call Standard for AArch64, see *Procedure Call Standard for the ARM 64-bit Architecture*.

ARMv8 supports single-precision (32-bit) and double-precision (64-bit) floating-point data types and arithmetic as defined by the IEEE 754 floating-point standard. It also supports the half-precision (16-bit) floating-point data type for data storage only, by supporting conversions between single-precision and half-precision data types and double-precision and half-precision data types.

The SIMD instructions provide packed *Single Instruction Multiple Data (SIMD)* and single-element scalar operations, and support:

- Single-precision and double-precision arithmetic in AArch64 state.
- Single-precision arithmetic only in AArch32 state.

Floating-point support in AArch64 state SIMD is IEEE 754-2008 compliant with:

- Configurable rounding modes.
- Configurable Default NaN behavior.
- Configurable Flush-to-zero behavior.

Floating-point computation using AArch32 Advanced SIMD instructions remains unchanged from ARMv7. A32 and T32 Advanced SIMD floating-point always uses ARM standard floating-point arithmetic and performs IEEE 754 floating-point arithmetic with the following restrictions:

- Denormalized numbers are flushed to zero, see *Flush-to-zero* on page A1-49.
- Only default NaNs are supported, see *NaN handling and the Default NaN* on page A1-50.
- The Round to Nearest rounding mode is used.
- Untrapped exception handling is used for all floating-point exceptions.

ARMv8 introduces new instructions for AArch32 state:

- Floating-point selection, see *VSEL* on page F8-3298.
- Floating-point maximum and minimum numbers, see *VMAXNM, VMINNM* on page F8-3168.
- Floating-point integer conversions with directed rounding modes, see *VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, Advanced SIMD)* on page F8-3114 and *VCVTA, VCVTN, VCVTP, VCVTM (between floating-point and integer, floating-point)* on page F8-3116.

- Floating-point round to integral floating-point, see *VRINTA, VRINTN, VRINTP, VRINTM (Advanced SIMD)* on page F8-3272, *VRINTA, VRINTN, VRINTP, VRINTM (floating-point)* on page F8-3274, *VRINTX (Advanced SIMD)* on page F8-3276, *VRINTX (floating-point)* on page F8-3278, *VRINTZ (Advanced SIMD)* on page F8-3280 and *VRINTZ, VRINTR (floating-point)* on page F8-3282.
- Floating-point conversions between half-precision and double-precision, see *VCVTB, VCVTT* on page F8-3118.

If trapping is supported, Floating-point exceptions, such as overflow or division by zero, can be handled without trapping. This applies to both floating-point and SIMD operations. When handled in this way, a Floating-point exception causes a cumulative status register bit to be set to 1 and a default result to be produced by the operation. For more information about Floating-point exceptions, see *Supported data types* on page A1-36.

In AArch64 state, the following registers control floating-point operation and return floating-point status information:

- The Floating-Point Control Register, FPCR, controls:
  - The half-precision format where applicable, FPCR.AHP bit.
  - Default NaN behavior, FPCR.DN bit.
  - Flush to zero behavior, FPCR.FZ bit.
  - Rounding mode support, FPCR.Rmode field.
  - Optional LEN and STRIDE fields associated with AArch32 execution, only supported for a context save and restore in AArch64. These fields are obsolete in ARMv8 and are either RAZ/WI or, when nonzero, cause an UNDEFINED instruction trap when an affected AArch32 instruction is executed.
  - Optional exception trap controls, the FPCR.{IDE, IXE, UFE, OFE, DZE, IOE} bits, see *Floating-point Exception traps* on page D1-1451.
- The Floating-Point Status Register, FPSR, provides:
  - Cumulative flags, FPSR.{IDC, IXC, UFC, OFC, DZC, IOC and QC}.
  - TheAArch32 floating-point comparison flags {N,Z,C,V}. These bits are RES0 if AArch32 floating-point is not supported.

    Note

    In AArch64, the process state flags, PSTATE.{N,Z,C,V} are used for all data processing compares and any associated conditional execution.

AArch32 state provides a single Floating-Point Status and Control Register, FPSCR, combining the FPCR and FPSR fields.

For system level information about the SIMD and floating-point support, see *Advanced SIMD and floating-point support* on page G1-3466.

A1.5.1 Instruction support

The floating-point and SIMD support includes the following types of instructions:

- Load and store for single elements and vectors of multiple elements.

  Note

  Single elements are also referred to as scalar elements.

- Data processing on single and multiple elements for both integer and floating-point data types.
- Floating-point conversion:
  - Half-precision, single-precision, and double-precision conversions.
  - Single-precision, double-precision, and fixed point integer conversions.
  - Single-precision, double-precision, and integer conversions.

- Floating-point rounding.

For more information on the floating-point and SIMD instructions in AArch64 state, see Chapter C3 *A64 Instruction Set Overview*.

For more information on the floating-point and Advanced SIMD instructions in AArch32 state, see Chapter F5 *T32 and A32 Instruction Sets Advanced SIMD and floating-point Encodings*

A1.5.2 Floating-point standards, and terminology

The ARM includes support for all the required features of ANSI/IEEE Std 754-2008, *IEEE Standard for Binary Floating-Point Arithmetic*, referred to as IEEE 754-2008. However, some terms in this manual are based on the 1985 version of this standard, referred to as IEEE 754-1985:

- ARM floating-point terminology generally uses the IEEE 754-1985 terms. This section summarizes how IEEE 754-2008 changes these terms.
- References to IEEE 754 that do not include the issue year apply to either issue of the standard.

Table A1-3 shows how the terminology in this manual differs from that used in IEEE 754-2008.

Table A1-3 Floating-point terminology

This manual	IEEE 754-2008
Normalized [a]	Normal
Denormal, or denormalized	Subnormal
Round towards Minus Infinity (RM)	roundTowardsNegative
Round towards Plus Infinity (RP)	roundTowardsPositive
Round towards Zero (RZ)	roundTowardZero
Round to Nearest (RN)	roundTiesToEven
Round to Nearest with Ties to Away	roundTiesToAway
Rounding mode	Rounding-direction attribute

a. *Normalized number* is used in preference to *normal number*, because of the other specific uses of *normal* in this manual.

A1.5.3 ARM standard floating-point input and output values

ARMv8 provides full IEEE 754 floating-point arithmetic support. In AArch32, floating-point operations performed using Advanced SIMD instructions are limited to *ARM standard floating-point operation*, regardless of the selected rounding mode in the FPSCR. Unlike AArch32, AArch64 SIMD floating point arithmetic is performed using the rounding mode selected by the FPCR.

ARM standard floating-point arithmetic supports the following input formats defined by the IEEE 754 floating-point standard:

- Zeros.
- Normalized numbers.
- Denormalized numbers are flushed to 0 before floating-point operations, see *Flush-to-zero* on page A1-49.
- NaNs.
- Infinities.

ARM standard floating-point arithmetic supports the Round to Nearest rounding mode defined by the IEEE 754 standard.

ARM standard floating-point arithmetic supports the following output result formats defined by the IEEE 754 standard:

- Zeros.
- Normalized numbers.
- Results that are less than the minimum normalized number are flushed to zero, see *Flush-to-zero*.
- NaNs produced in floating-point operations are always the default NaN, see *NaN handling and the Default NaN* on page A1-50.
- Infinities.

A1.5.4 Flush-to-zero

The performance of floating-point processing can be reduced when doing calculations involving denormalized numbers and Underflow exceptions. In many algorithms, this performance can be recovered, without significantly affecting the accuracy of the final result, by replacing the denormalized operands and intermediate results with zeros. To permit this optimization, ARM floating-point implementations have a special processing mode called *Flush-to-zero* mode. AArch32 Advanced SIMD floating-point instructions always use Flush-to-zero mode.

Behavior in Flush-to-zero mode differs from normal IEEE 754 arithmetic in the following ways:

- All inputs to floating-point operations that are double-precision denormalized numbers or single-precision denormalized numbers are treated as though they were zero. This causes an Input Denormal exception, but does not cause an Inexact exception. The Input Denormal exception occurs only in Flush-to-zero mode.

  In AArch32, the FPSCR contains a cumulative exception bit FPSCR.IDC and optional trap enable bit FPSCR.IDE corresponding to Input Denormal exception.

  In AArch64 the FPSR contains a cumulative exception bit FPSR.IDC and optional trap enable bit FPCR.IDE corresponding to the Input Denormal exception.

  The occurrence of all exceptions except Input Denormal is determined using the input values after flush-to-zero processing has occurred.

- The result of a floating-point operation is flushed to zero if the result of the operation before rounding satisfies the condition:

  $0 < \texttt{Abs(result)} <$ MinNorm, where:

  — MinNorm is 2^{-126} for single-precision.

  — MinNorm is 2^{-1022} for double-precision.

  This causes the FPSR.UFC bit to be set to 1, and prevents any Inexact exception from occurring for the operation.

  Underflow exceptions occur only when a result is flushed to zero.

  In all implementations Underflow exceptions that occur in Flush-to-zero mode are always treated as untrapped, even when the Underflow trap enable bit, FPCR.UFE, is set to 1.

- An Inexact exception does not occur if the result is flushed to zero, even though the final result of zero is not equivalent to the value that would be produced if the operation were performed with unbounded precision and exponent range.

When an input or a result is flushed to zero the value of the sign bit of the zero is preserved. That is, the sign bit of the zero matches the sign bit of the input or result that is being flushed to zero.

Flush-to-zero mode has no effect on half-precision numbers that are inputs to floating-point operations, or results from floating-point operations.

Note

Flush-to-zero mode is incompatible with the IEEE 754 standard, and must not be used when IEEE 754 compatibility is a requirement. Flush-to-zero mode must be used with care. Although it can improve performance on some algorithms, there are significant limitations on its use. These are application dependent:

- On many algorithms, it has no noticeable effect, because the algorithm does not normally use denormalized numbers.
- On other algorithms, it can cause exceptions to occur or seriously reduce the accuracy of the results of the algorithm.

A1.5.5 NaN handling and the Default NaN

The IEEE 754 standard specifies that:

- An operation that produces an Invalid Operation floating-point exception generates a quiet NaN as its result if that exception is untrapped.
- An operation involving a quiet NaN operand, but not a signaling NaN operand, returns an input NaN as its result.

The floating-point processing behavior when Default NaN mode is disabled adheres to this, with the following additions:

- If an untrapped Invalid Operation floating-point exception is produced, the quiet NaN result is derived from:
  - The first signaling NaN operand, if the exception was produced because at least one of the operands is a signaling NaN.
  - Otherwise, the default NaN.
- If an untrapped Invalid Operation floating-point exception is not produced, but at least one of the operands is a quiet NaN, the result is derived from the first quiet NaN operand.

Depending on the operation, the exact value of a derived quiet NaN result may differ in both sign and number of fraction bits from its source.For a quiet NaN result derived from signaling NaN operand, the most-significant fraction bit is set to 1.

Note

- In these descriptions, *first operand* relates to the left-to-right ordering of the arguments to the pseudocode function that describes the operation.
- The IEEE 754 standard specifies that the sign bit of a NaN has no significance.

The floating-point and SIMD processing behavior when Default NaN mode is enabled is that the Default NaN is the result of all floating-point operations that either:

- Generate untrapped Invalid Operation floating-point exceptions.
- Have one or more quiet NaN inputs, but no signaling NaN inputs.

Table A1-4 on page A1-51 shows the format of the default NaN for ARM floating-point operations.

Default NaN mode is selected for the floating-point processing by setting the FPCR.DN bit to 1.

Other aspects of the functionality of the Invalid Operation exception are not affected by Default NaN mode. These are that:

- If untrapped, it causes the FPSR.IOC bit be set to 1.
- If trapped, it causes a user trap handler to be invoked.

Table A1-4 Default NaN encoding

	Half-precision, IEEE Format	Single-precision	Double-precision
Sign bit	0	0	0
Exponent	`0x1F`	`0xFF`	`0x7FF`
Fraction	Bit[9] == 1, bits[8:0] == 0	bit[22] == 1, bits[21:0] == 0	bit[51] == 1, bits[50:0] == 0

A1.6 Cryptographic Extension

The presence of this Extension in an implementation is subject to export license controls. The Cryptographic Extension is an extension of the SIMD support and operates on the vector register file. It provides instructions for the acceleration of encryption and decryption to support the following:

- AES.
- SHA1.
- SHA2-256.

Large polynomial multiplies are included as part of the Cryptographic Extension, see *PMULL, PMULL2* on page C7-1089.

A1.7 The ARM memory model

The ARM memory model supports:

- Generating an exception on an unaligned memory access.
- Restricting access by applications to specified areas of memory.
- Translating virtual addresses provided by executing instructions into physical addresses.
- Altering the interpretation of multi-byte data between big-endian and little-endian.
- Controlling the order of accesses to memory.
- Controlling caches and address translation structures.
- Synchronizing access to shared memory by multiple PEs.

Virtual address (VA) support depends on the Execution state, as follows:

AArch64 state

Supports 64-bit virtual addressing, with the Translation Control Register determining the supported VA range. Execution at EL1 and EL0 supports two independent VA ranges, each with its own translation controls.

AArch32 state

Supports 32-bit virtual addressing, with the Translation Control Register determining the supported VA range. For execution at EL1 and EL0, system software can split the VA range into two subranges, each with its own translation controls.

The supported physical address space is IMPLEMENTATION DEFINED, and can be discovered by system software.

Regardless of the Execution state, the *Virtual Memory System Architecture* (VMSA) can translate VAs to blocks or pages of memory anywhere within the supported physical address space.

For more information, see:

For execution in AArch64 state

Part B

The AArch64 Application Level Architecture

Chapter B1
The AArch64 Application Level Programmers' Model

This chapter gives an application level view of the ARM programmers' model. It contains the following sections:

B1.1 About the Application level programmers' model

This chapter contains the programmers' model information required for application development.

The information in this chapter is distinct from the system information required to service and support application execution under an operating system, or higher level of system software. However, some knowledge of the system information is needed to put the Application level programmers' model into context.

Depending on the implementation choices, the architecture supports multiple levels of execution privilege, indicated by different *Exception levels* that number upwards from EL0 to EL3. EL0 corresponds to the lowest privilege level and is often described as unprivileged. The Application level programmers' model is the programmers' model for software executing at EL0. For more information see *Exception levels* on page D1-1400.

System software determines the Exception level, and therefore the level of privilege, at which software runs. When an operating system supports execution at both EL1 and EL0, an application usually runs unprivileged at EL0. This:

- Permits the operating system to allocate system resources to an application in a unique or shared manner.
- Provides a degree of protection from other processes, and so helps protect the operating system from malfunctioning software.

This chapter indicates where some system level understanding is necessary, and where relevant it gives a reference to the system level description.

Execution at any Exception level above EL0 is often referred to as privileged execution.

For more information on the system level view of the architecture refer to Chapter D1 *The AArch64 System Level Programmers' Model*.

B1.2 Registers in AArch64 Execution state

This section describes the registers and process state visible at EL0 when executing in the AArch64 state. It includes the following:

- *Registers in AArch64 state*.
- *Process state, PSTATE* on page B1-62.
- *System registers* on page B1-62.

B1.2.1 Registers in AArch64 state

In the AArch64 application level view, an ARM Processing element has:

R0-R30 31 general-purpose registers, R0 to R30. Each register can be accessed as:

- A 64-bit general-purpose register named X0 to X30.
- A 32-bit general-purpose register named W0 to W30.

See the register name mapping in Figure B1-1.

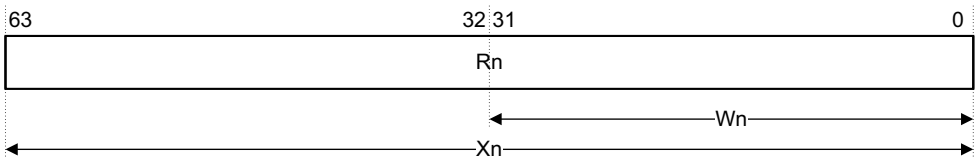

Figure B1-1 General-purpose register naming

The X30 general-purpose register is used as the procedure call link register.

Note

In instruction encodings, the value `0b11111` (31) is used to indicate the ZR (zero register). This indicates that the argument takes the value zero, but does not indicate that the ZR is implemented as a physical register.

SP A 64-bit dedicated Stack Pointer register. The least significant 32-bits of the stack-pointer can be accessed via the register name WSP.

The use of SP as an operand in an instruction, indicates the use of the current stack pointer.

Note

Stack pointer alignment to a 16-byte boundary is configurable at EL1. For more information see the *Procedure Call Standard for the ARM 64-bit Architecture*.

PC A 64-bit Program Counter holding the address of the current instruction.

Software cannot write directly to the PC. It can only be updated on a branch, exception entry or exception return.

Note

Attempting to execute an A64 instruction that is not word-aligned generates an Alignment fault, see *PC alignment checking* on page D1-1415.

V0-V31 32 SIMD and floating-point registers, V0 to V31. Each register can be accessed as:

- A 128-bit register named Q0 to Q31.
- A 64-bit register named D0 to D31.
- A 32-bit register named S0 to S31.
- A 16-bit register named H0 to H31.
- An 8-bit register named B0 to B31.

- A 128-bit vector of elements.
- A 64-bit vector of elements.

Where the number of bits described by a register name does not occupy an entire SIMD and floating-point register, it refers to the least significant bits. See Figure B1-2.

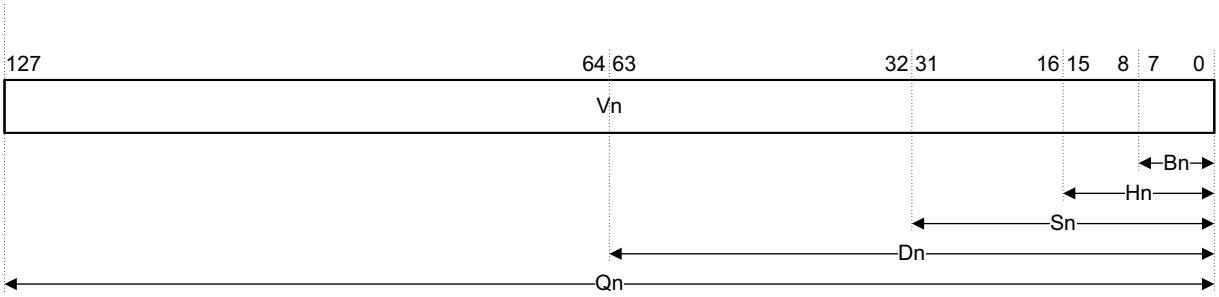

Figure B1-2 SIMD and floating-point register naming

For more information about data types and vector formats, see *Supported data types* on page A1-36.

FPCR, FPSR Two SIMD and floating-point control and status registers, FPCR and FPSR.

See *Registers for instruction processing and exception handling* on page D1-1408 for more information on the registers.

Pseudocode details of registers in AArch64 state

In the pseudocode functions that access registers:

- The assignment form is used for register writes.
- The non-assignment for register reads.

The uses of the `X[]` function are:

- Reading or writing X0-X30, using n to index the required register.
- Reading the zero register ZR, accessed as `X[31]`.

Note

The pseudocode use of X[31] to represent the zero register does not indicate that hardware must implement this register.

```
// X[] - assignment form
// =====================
// Write to general-purpose register from either a 32-bit and 64-bit value.

X[integer n] = bits(width) value
    assert n >= 0 && n <= 31;
    assert width IN {32,64};
    if n != 31 then
        _R[n] = ZeroExtend(value);
    return;

// X[] - non-assignment form
// =========================
// Read from general-purpose register with implicit slice of 8, 16, 32 or 64 bits.

bits(width) X[integer n]
    assert n >= 0 && n <= 31;
    assert width IN {8,16,32,64};
    if n != 31 then
        return _R[n]<width-1:0>;
    else
```

```
        return Zeros(width);
```

The _R[] function provides a view of the physical array of the physical general-purpose registers.

```
array bits(64) _R[0..30];
```

The SP[] function is used to read or write the current SP. This function has prototypes:

```
SP[] = bits(width) value;

bits(width) SP[];
```

The PC[] function is used to read the PC. This function has prototype:

```
bits(64) PC[];
```

The _V[] function provides a view of the physical array of the physical SIMD and floating-point registers.

```
array bits(128) _V[0..31];
```

The V[] function is used to read or write V0-V31, using n to index the required register.

```
// V[] - assignment form
// =====================
// Write to SIMD&FP register with implicit extension from
// 8, 16, 32, 64 or 128 bits.

V[integer n] = bits(width) value
    assert n >= 0 && n <= 31;
    assert width IN {8,16,32,64,128};
    _V[n] = ZeroExtend(value);
    return;

// V[] - non-assignment form
// =========================
// Read from SIMD&FP register with implicit slice of 8, 16
// 32, 64 or 128 bits.

bits(width) V[integer n]
    assert n >= 0 && n <= 31;
    assert width IN {8,16,32,64,128};
    return _V[n]<width-1:0>;
```

The Vpart[] function is used to read or write the lower or upper half of V0-V31, using n to index the required register, and part to indicate the required half.

```
// Vpart[] - non-assignment form
// =============================
// Reads a 128-bit SIMD&FP register in up to two parts:
//  part 0 returns the bottom 8, 16, 32 or 64 bits of the register;
//  part 1 returns only the top 64 bits of the register.

bits(width) Vpart[integer n, integer part]
    assert n >= 0 && n <= 31;
    assert part IN {0, 1};
    if part == 0 then
        assert width IN {8,16,32,64};
        return _V[n]<width-1:0>;
    else
        assert width == 64;
        return _V[n]<127:64>;

// Vpart[] - assignment form
// =========================
// Write a 128-bit SIMD&FP register in up to two parts:
//  part 0 zero extends a 8, 16, 32, or 64-bit value to fill the whole register;
//  part 1 inserts a 64-bit value into the top 64 bits of the register.

Vpart[integer n, integer part] = bits(width) value
    assert n >= 0 && n <= 31;
```

```
assert part IN {0, 1};
if part == 0 then
    assert width IN {8,16,32,64};
    _V[n] = ZeroExtend(value);
else
    assert width == 64;
    _V[n]<127:64> = value<63:0>;
```

B1.2.2 Process state, PSTATE

For AArch64, PSTATE holds process state related information. The following PSTATE information is accessible at EL0

The Data processing flags

N Negative condition flag. If the result is regarded as a two's complement signed integer, then the PE sets N to 1 if the result is negative, and sets N to 0 if it is positive or zero.

Z Zero condition flag. Set to 1 if the result of the instruction is zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C Carry condition flag. Set to 1 if the instruction results in a carry condition, for example an unsigned overflow that is the result of an addition.

V Overflow condition flag. Set to 1 if the instruction results in an overflow condition, for example a signed overflow that is the result of an addition.

The Exception masking bits

D Debug exception mask bit. When EL0 is enabled to modify the mask bits, this bit is visible and can be modified. However, this bit is architecturally ignored at EL0.

A System error mask bit, referred to as an external asynchronous abort bit in the earlier versions of the architecture.

I IRQ mask bit.

F FIQ mask bit.

The possible values of each bit are:

0 Exception not masked

1 Exception masked

See *Process state, PSTATE* on page D1-1413 for the system level view of PSTATE.

B1.2.3 System registers

System registers provide support for execution control, status and general system configuration. The majority of the System registers are not accessible at EL0.

However, some system registers can be configured to allow access from software executing at EL0. Any access from EL0 to a system register with the access right disabled causes the instruction to behave as an UNDEFINED instruction. The registers that can be accessed from EL0 are:

Cache ID registers The CTR_EL0 and DCZID_EL0 registers provide implementation parameters for EL0 cache management support.

Debug registers A debug communications channel is supported by the MDCCSR_EL0, DBGDTR_EL0, DBGDTRRX_EL0 and DBGDTRTX_EL0 registers.

Performance Monitors registers

See *Performance Monitors support* on page B1-63.

Thread ID registers The TPIDR_EL0 and TPIDRRO_EL0 registers are two thread ID registers with different access rights.

Timer registers In ARMv8 the following operations are performed:

- Read access to the system counter clock frequency using CNTFRQ_EL0.
- Physical and virtual timer count registers, CNTPCT_EL0 and CNTVCT_EL0.
- Physical up-count comparison, down-count value and timer control registers, CNTP_CVAL_EL0, CNTP_TVAL_EL0, and CNTP_CTL_EL0.
- Virtual up-count comparison, down-count value and timer control registers, CNTV_CVAL_EL0, CNTV_TVAL_EL0, and CNTV_CTL_EL0.

Performance Monitors support

The ARMv8 architecture defines optional Performance Monitors.

The basic form of the Performance Monitors is:

- A 64-bit cycle counter.
- Up to a maximum of 32 IMPLEMENTATION DEFINED event counters, where the number is identified by the PMCR_EL0.N field.
- System register access to the cycle counter and event registers, and related controls for:
  - Enabling and resetting counters.
  - Flagging overflows.
  - Generating interrupts on overflow.

  Software can enable the cycle counter independently of the event counters.

Software executing at EL1 or a higher Exception level, for example an operating system, can enable access to the counters from EL0. This allows an application to monitor its own performance with fine grain control without requiring operating system support. For example, an application might implement per-function performance monitoring.

For details on the features, configuration and control of the Performance Monitors, see Chapter D5 *The Performance Monitors Extension*.

EL0 access to Performance Monitors

To allow application code to make use of the Performance Monitors, software executing at a higher Exception level must set the following bits in the PMUSERENR_EL0 system register:

EN When set to 1, access to all Performance Monitors registers is allowed at EL0, except for writes to PMUSERENR_EL0, and reads/writes of PMINTENSET_EL1 and PMINTENCLR_EL1.

ER When set to 1, read access to event counters is allowed at EL0. This includes read/write access to PMSELR_EL0, so that the event counter to read through PMXEVCNTR_EL0 can be set.

CR When set to 1, read access to PMCCNTR_EL0 is allowed at EL0.

SW When set to 1, write access to PMSWINC_EL0 is allowed at EL0.

Note

Register PMUSERENR_EL0 is always read-only at EL0.

B1.3 Software control features and EL0

The following sections describe the EL0 view of the ARMv8 software control features:

- *Exception handling*.
- *Wait for Interrupt and Wait for Event*.
- *The YIELD instruction*.
- *Application level cache management*.
- *Debug events* on page B1-65.

B1.3.1 Exception handling

In the ARM architecture, an *exception* causes a change of program flow. Execution of an exception handler starts, at an Exception level higher than EL0, from a defined vector that relates to the exception taken.

Exceptions include:

- Interrupts.
- Memory system aborts.
- Undefined instructions.
- System calls.
- Secure monitor or Hypervisor traps.

Most details of exception handling are not visible to application level software, and are described in Chapter D1 *The AArch64 System Level Programmers' Model*.

The `SVC` instruction causes a Supervisor Call exception. This provides a mechanism for unprivileged software to make a system call to an operating system.

B1.3.2 Wait for Interrupt and Wait for Event

Issuing a `WFI` instruction indicates that no further execution is required until a WFI wake-up event occurs, see *Wait For Interrupt* on page D1-1506. This permits entry to a low-power state.

Issuing a `WFE` instruction indicates that no further execution is required until a WFE wake-up event occurs, see *Wait for Event mechanism and Send event* on page D1-1503. This permits entry to a low-power state.

B1.3.3 The YIELD instruction

The `YIELD` instruction provides a hint that the task performed by a thread is of low importance so that it could yield, see *YIELD* on page C6-768. This mechanism can be used to improve overall performance in an *Symmetric Multi-Threading* (SMT) or *Symmetric Multi-Processing* (SMP) system.

Examples of when the `YIELD` instruction might be used include a thread that is sitting in a spin-lock, or where the arbitration priority of the snoop but in an SMP system is modified. The `YIELD` instruction permits binary compatibility between SMT and SMP systems.

The `YIELD` instruction is a `NOP` (No Operation) hint instruction.

The `YIELD` instruction has no effect in a single-threaded system, but developers of such systems can use the instruction to flag its intended use for future migration to a multiprocessor or multithreading system. Operating systems can use `YIELD` in places where a yield hint is wanted, knowing that it is treated as a `NOP` if there is no implementation benefit.

B1.3.4 Application level cache management

A small number of cache management instructions can be enabled at EL0 from higher levels of privilege using the SCTLR_EL1 system register. Any access from EL0 to an operation with the access right disabled causes the instruction to behave as an UNDEFINED instruction.

About the available operations, see *Application level cache instructions* on page B2-72.

B1.3.5 Debug events

The debug logic is responsible for generating debug events. Most aspects of debug events are not visible to application level software, and are described in Chapter H1 *Introduction to External Debug*. Aspects that are visible to application level software include:

- The `BKPT` instruction, which causes a BKPT instruction debug event to occur.
- The `DBG` instruction, which provides a hint to the debug system.
- The `HLT` instruction, which causes entry to Debug state.

Chapter B2
The AArch64 Application Level Memory Model

This chapter gives an application level view of the memory model. It contains the following sections:

Note

In this chapter, system register names usually link to the description of the register in Chapter D7 *AArch64 System Register Descriptions*, for example SCTLR_EL1.

B2.1 Address space

Address calculations are performed using 64-bit registers. However, supervisory software can configure the top eight address bits for use as a tag, as described in *Address tagging in AArch64 state* on page D4-1634. If this is done, address bits[63:56]:

- Are not considered when determining whether the address is valid.
- Are never propagated to the program counter.

Supervisory software determines the valid address range. Attempting to access an address that is not valid generates an MMU fault.

Address calculations are performed modulo 2^{64}.

The result of an address calculation is UNKNOWN if it overflows or underflows:

- The 64-bit address range A[63:0], where tagged addressing is not used.
- The 56-bit address range A[55:0], where tagged addressing is used.

Memory accesses use the `Mem[]` function.

The `Mem[]` function makes an access of the required type. If supervisory software configures the top eight address bits for use as a tag, the top eight address bits are ignored.

```
bits(size*8) Mem[bits(64) address, integer size, AccType acctype]
    assert size IN {1, 2, 4, 8, 16};

Mem[bits(64) address, integer size, AccType acctype] = bits(size*8) value;
```

The `AccType` enumeration defines the different access types:

```
enumeration AccType {AccType_NORMAL, AccType_VEC,       // Normal loads and stores
                     AccType_STREAM, AccType_VECSTREAM, // Streaming loads and stores
                     AccType_ATOMIC,                    // Atomic loads and stores
                     AccType_ORDERED,                   // Load-Acquire and Store-Release
                     AccType_UNPRIV,                    // Load and store unprivileged
                     AccType_IFETCH,                    // Instruction fetch
                     AccType_PTW,                       // Page table walk
                     // Other operations
                     AccType_DC,                        // Data cache maintenance
                     AccType_IC,                        // Instruction cache maintenance
                     AccType_AT};                       // Address translation
```

Note

- Chapter D3 *The AArch64 System Level Memory Model* and Chapter D4 *The AArch64 Virtual Memory System Architecture* include descriptions of memory system features that are transparent to the application, including memory access, address translation, memory maintenance instructions, and alignment checking and the associated fault handling. These chapters also include pseudocode descriptions of these operations.
- For information on the pseudocode that relates to memory accesses, see *Basic memory access* on page D3-1623, *Unaligned memory access* on page D3-1624, and *Aligned memory access* on page D3-1623.

B2.2 Memory type overview

ARMv8 provides the following mutually-exclusive memory types:

Normal This is generally used for bulk memory operations, both read-write and read-only operations.

Device The ARM architecture forbids speculative reads of any type of Device memory. This means Device memory types are suitable attributes for read-sensitive locations.

Locations of the memory map that are assigned to peripherals are usually assigned the Device memory attribute.

Device memory has additional attributes that have the following effects:

- They prevent aggregation of reads and writes, maintaining the number and size of the specified memory accesses. See *Gathering* on page B2-94.
- They preserve the access order and synchronization requirements, both for accesses to a single peripheral and where there is a synchronization requirement on the observability of one or more memory write and read accesses. See *Reordering* on page B2-95
- They indicate whether a write can be acknowledged other than at the end point. See *Early Write Acknowledgement* on page B2-95.

For more information on Normal memory and Device memory, see *Memory types and attributes* on page B2-89.

Note

Earlier versions of the ARM architecture defined a single Device memory type and a Strongly-Ordered memory type. A *Note* in *Device memory* on page B2-91 describes how these memory types map onto the ARMv8 memory types.

B2.3 Caches and memory hierarchy

The implementation of a memory system depends heavily on the microarchitecture and therefore many details of the memory system are IMPLEMENTATION DEFINED. ARMv8 defines the application level interface to the memory system, including a hierarchical memory system with multiple levels of cache. This section describes an application level view of this system. It contains the subsections:

- *Introduction to caches*.
- *Memory hierarchy*.
- *Application level cache instructions* on page B2-72
- *Implication of caches for the application programmer* on page B2-72.
- *Preloading caches* on page B2-74.

B2.3.1 Introduction to caches

A cache is a block of high-speed memory that contains a number of entries, each consisting of:

- Main memory address information, commonly known as a *tag*.
- The associated data.

Caches increase the average speed of a memory access. Caching takes account of two principles of locality:

Spatial locality

An access to one location is likely to be followed by accesses to adjacent locations. Examples of this principle are:

- Sequential instruction execution.
- Accessing a data structure.

Temporal locality

An access to an area of memory is likely to be repeated in a short time period. An example of this principle is the execution of a software loop.

To minimize the quantity of control information stored, the spatial locality property groups several locations together under the same tag. This logical block is commonly known as a *cache line*. When data is loaded into a cache, access times for subsequent loads and stores are reduced, resulting in overall performance benefits. An access to information already in a cache is known as a *cache hit*, and other accesses are called *cache misses*.

Normally, caches are self-managing, with the updates occurring automatically. Whenever the PE accesses a cacheable memory location, the cache is checked. If the access is a cache hit, the access occurs in the cache. Otherwise, the access is made to memory. Typically, when making this access, a cache location is allocated and the cache line loaded from memory. ARMv8 permits different cache topologies and access policies, provided they comply with the memory coherency model described in this manual.

Caches introduce a number of potential problems, mainly because:

- Memory accesses can occur at times other than when the programmer would expect them.
- A data item can be held in multiple physical locations.

B2.3.2 Memory hierarchy

Typically memory close to a PE has very low latency, but is limited in size and expensive to implement. Further from the PE it is common to implement larger blocks of memory but these have increased latency. To optimize overall performance, an ARMv8 memory system can include multiple levels of cache in a hierarchical memory system that exploits this trade-off between size and latency. Figure B2-1 on page B2-71 shows an example of such a system in an ARMv8-A system that supports virtual addressing.

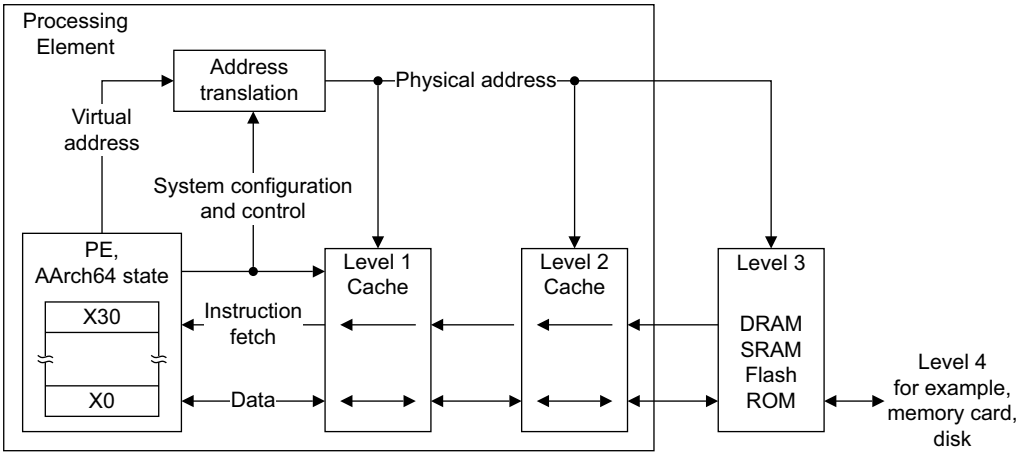

Figure B2-1 Multiple levels of cache in a memory hierarchy

Note

In this manual, in a hierarchical memory system, Level 1 refers to the level closest to the Processing Element, as shown in Figure B2-1.

Instructions and data can be held in separate caches or in a unified cache. A cache hierarchy can have one or more levels of separate instruction and data caches, with one or more unified caches located at the levels closest to the main memory. Memory coherency for cache topologies can be defined by two conceptual points:

Point of Unification (PoU)

The point at which the instruction cache, data cache, and translation table walks of a particular PE are guaranteed to see the same copy of a memory location. In many cases, the point of unification is the point in a uniprocessor memory system by which the instruction and data caches and the translation table walks have merged. The point of unification might coincide with the point of coherency.

Point of Coherency (PoC)

The point at which all agents that can access memory are guaranteed to see the same copy of a memory location. In many cases this is effectively the main system memory, although the architecture does not prohibit the implementation of caches beyond the PoC that have no effect on the coherency between memory system agents.

See also *Overview of the cache maintenance instructions* on page D3-1604.

The cacheability and shareability memory attributes

Cacheability and shareability are two attributes that describe the memory hierarchy in a multiprocessing system:

Cacheability This term defines whether memory locations are allowed to be allocated into a cache or not. Cacheability can be defined independently for Inner and Outer cacheability locations.

Shareability This term defines whether memory locations are shareable between different agents in a system. Marking a memory location as shareable for a particular domain requires hardware to ensure that the location is coherent for all agents in that domain. Shareability can be defined independently for Inner and Outer shareability domains.

For more information about cacheability and shareability see *Memory types and attributes* on page B2-89.

B2.3.3 Application level cache instructions

In the ARM architecture, the application level is defined as *Exception level 0* (EL0). The architecture defines a set of cache maintenance instructions that software can use to manage cache coherency. Software executing at a higher Exception level can enable EL0 access to the following:

- The data cache maintenance instructions, `DC CVAU`, `DC CVAC`, and `DC CIVAC`. See *Data cache maintenance instructions (DC*)* on page D3-1609.
- The instruction cache maintenance instruction, `IC IVAU`. See *Instruction cache maintenance instructions (IC*)* on page D3-1609.
- The cache type register. See CTR_EL0.
- The data cache zero instruction, `DC ZVA`. See *Data cache zero instruction* on page D3-1616.

These instructions are UNDEFINED from EL0 unless software executing at a higher Exception level has enabled them. See *Cache maintenance instructions* on page D3-1608.

For all of these instructions, if the addresses do not have read access permission at EL0, executing these instructions at EL0 generates a Permission fault.

For more information about the system controls, see *Cache support* on page D3-1599.

B2.3.4 Implication of caches for the application programmer

In normal operation, the caches are largely invisible to the application programmer. However they can become visible when there is a breakdown in the coherency of the caches. Such a breakdown can occur:

- When memory locations are updated by other agents in the system that do not use hardware management of coherency.
- When memory updates made from the application software must be made visible to other agents in the system, without the use of hardware management of coherency.

For example:

- In the absence of hardware management of coherency of DMA accesses, in a system with a DMA controller that reads memory locations that are held in the data cache of a PE, a breakdown of coherency occurs when the PE has written new data in the data cache, but the DMA controller reads the old data held in memory.
- In a Harvard cache implementation, where there are separate instruction and data caches, a breakdown of coherency occurs when new instruction data has been written into the data cache, but the instruction cache still contains the old instruction data.

Data coherency issues

Software can ensure the data coherency of caches in the following ways:

- By not using the caches in situations where coherency issues can arise. This can be achieved by:
  - Using Non-cacheable or, in some cases, Write-Through Cacheable memory.
  - Not enabling caches in the system.
- By using cache maintenance instructions to manage the coherency issues in software. See *Application level cache instructions*.
- By using hardware coherency mechanisms to ensure the coherency of data accesses to memory for cacheable locations by observers within the different shareability domains, see *Non-shareable Normal memory* on page B2-91 and *Shareable, Inner Shareable, and Outer Shareable Normal memory* on page B2-90.

Note

The performance of these hardware coherency mechanisms is highly implementation-specific. In some implementations the mechanism suppresses the ability to cache shareable locations. In other implementations, cache coherency hardware can hold data in caches while managing coherency between observers within the shareability domains.

Note

Not all these mechanisms are directly available to software operating at EL0 and might involve interaction with software operating at a higher Exception level.

Synchronization and coherency issues between data and instruction accesses

How far ahead of the current point of execution instructions are fetched from is IMPLEMENTATION DEFINED. Such prefetching can be either a fixed or a dynamically varying number of instructions, and can follow any or all possible future execution paths. For all types of memory:

- The PE might have fetched the instructions from memory at any time since the last *Context synchronization operation* on that PE.
- Any instructions fetched in this way might be executed multiple times, if this is required by the execution of the program, without being re-fetched from memory.

The ARM architecture does not require the hardware to ensure coherency between instruction caches and memory, even for locations of shared memory.

If software requires coherency between instruction execution and memory, it must manage this coherency using the `ISB` and `DSB` memory barriers and cache maintenance instructions. The following code sequence can be used for this purpose:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn         ; Clean data cache by VA to point of unification (PoU)
        DSB ISH             ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn         ; Invalidate instruction cache by VA to PoU
        DSB ISH             ; Ensure completion of the invalidations
        ISB                 ; Synchronize the fetched instruction stream
```

Note

- For Non-cacheable or Write-Through accesses, the clean data cache by VA instruction is not required. However, the invalidate instruction cache instruction is required because the ARMv8-A AArch64 architecture allows Non-cacheable accesses to held in an instruction cache. See *Non-cacheable accesses and instruction caches* on page D3-1604.
- This code can be used when the thread of execution modifying the code is the same thread of execution that is executing the code. The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization. See *Concurrent modification and execution of instructions* on page B2-80.
- The system software controls whether these cache maintenance instructions are available to the application level by setting SCTLR_EL1.UCI.

B2.3.5 Preloading caches

The ARM architecture provides memory system hints `PRFM`, `LDNP`, and `STNP` that software can use to communicate the expected use of memory locations to the hardware. The memory system can respond by taking actions that are expected to speed up the memory accesses if they occur. The effect of these memory system hints is IMPLEMENTATION DEFINED. Typically, implementations use this information to bring the data or instruction locations into caches.

The Preload instructions are hints, and so implementations can treat them as `NOP`s without affecting the functional behavior of the device. The instructions cannot generate synchronous Data Abort exceptions, but the resulting memory system operations might, under exceptional circumstances, generate an asynchronous external abort, which is taken using an SError interrupt exception. For more information, see *ISS encoding for an exception from a Data abort exception* on page D7-1849.

`PrefetchHint{}` defines the prefetch hint types:

```
enumeration PrefetchHint {Prefetch_READ, Prefetch_WRITE, Prefetch_EXEC};
```

The `Hint_Prefetch()` function signals to the memory system that memory accesses of the type `hint` to or from the specified `address` are likely to occur in the near future. The memory system might take some action to speed-up the memory accesses when they do occur, such as preloading the specified address into one or more caches as indicated by the innermost cache level `target` and non-temporal hint `stream`.

```
Hint_Prefetch(bits(64) address, PrefetchHint hint, integer target, boolean stream);
```

For more information on `PRFM` and Load/Store instructions that provide hints to the memory system, see *Prefetch memory* on page C3-140 and *Load/Store SIMD and Floating-point Non-temporal pair* on page C3-138.

B2.4 Alignment support

This section describes alignment support. It contains the following subsections:

- *Instruction alignment*.
- *Alignment of data accesses*.
- *Unaligned data access restrictions*.

B2.4.1 Instruction alignment

A64 instructions must be word-aligned.

Attempting to fetch an instruction from a misaligned location results in a Misaligned PC fault. See *PC alignment checking* on page D1-1415.

B2.4.2 Alignment of data accesses

An unaligned access to any type of Device memory causes an Alignment fault.

The alignment requirements for accesses to Normal memory are as follows:

- For all instructions that load or store a single or multiple registers, other than Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release, if the address that is accessed is not aligned to the size of the data element being accessed, then one of the following occurs:
  - An Alignment fault is generated.
  - An unaligned access is performed.

  SCTLR_ELx.A at the current Exception level can be configured to enable an alignment check, and thereby determine which of these two options is used.

  Note

  - The SCTLR_EL1.A bit that is applicable to software running at EL0, can only be accessed from EL1 or above.
  - Alignment checks are based on element size, not overall access size. This affects SIMD element and structure loads and stores, and also Load/Store pair instructions.

- For all Load-Exclusive/Store-Exclusive and Load-Acquire/Store-Release memory accesses that access a single element or a pair of elements, an Alignment fault is generated if the address being accessed is not aligned to the size of the data structure being accessed.

A failed alignment check results in an Alignment fault, which is taken as a Data Abort exception. These exceptions are taken at the lowest Exception level that can handle the exception, consistent with the basic requirement that the Exception level never decreases on an exception. Therefore:

- Alignment faults at EL0 or EL1 are taken at EL1 unless redirected by HCR_EL2.TGE
- Alignment faults at EL2 are taken at EL2.
- Alignment faults at EL3 are taken at EL3.

B2.4.3 Unaligned data access restrictions

The following points apply to unaligned data accesses in ARMv8:

- Accesses are not guaranteed to be single-copy atomic except at the byte access level, see *Atomicity in the ARM architecture* on page B2-79.
- Unaligned accesses typically takes a number of additional cycles to complete compared to a naturally-aligned access.
- An operation that performs an unaligned access can abort on any memory access that it makes, and can abort on more than one access. This means that an unaligned access that occurs across a page boundary can generate an abort on either side of the boundary.

B2.5 Endian support

General description of endianness in the ARM architecture describes the relationship between endianness and memory addressing in the ARM architecture.

The following subsections then describe the endianness schemes supported by the architecture:

- *Instruction endianness* on page B2-77.
- *Data endianness* on page B2-77.

B2.5.1 General description of endianness in the ARM architecture

This section only describes memory addressing and the effects of endianness for data elements up to quadwords of 128 bits. However, this description can be extended to apply to larger data elements.

For an address A, Figure B2-2 shows, for big-endian and little-endian memory systems, the relationship between:

- The quadword at address A.
- The doubleword at address A and A+8.
- The words at addresses A, A+4, A+8, and A+12.
- The halfwords at addresses A, A+2, A+4, A+6, A+8, A+10, A+12, and A+14.
- The bytes at addresses A, A+1, A+2, A+3, A+4, A+5, A+6, A+7, A+8, A+9, A+10, A+11, A+12, A+13, A+14, and A+15.

The terms in Figure B2-2 have the following definitions:

B_A Byte at address A.
HW_A Halfword at address A.
MSByte Most-significant byte.
LSByte Least-significant byte.

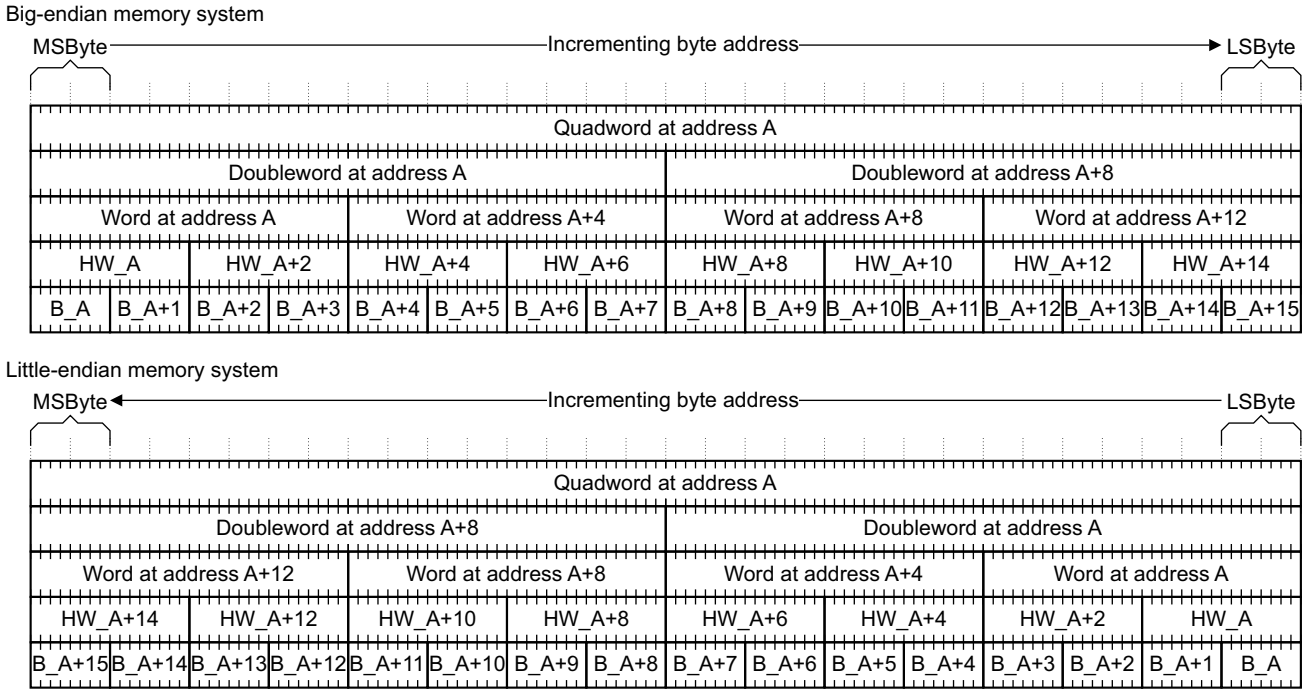

Figure B2-2 Endianness relationships

The big-endian and little-endian mapping schemes determine the order in which the bytes of a quadword, doubleword, word or halfword are interpreted. For example, a load of a word from address `0x1000` always results in an access to the bytes at memory locations `0x1000`, `0x1001`, `0x1002`, and `0x1003`. The endianness mapping scheme determines the significance of these four bytes.

B2.5.2 Instruction endianness

In ARMv8-A, A64 instructions have a fixed length of 32 bits and are always little-endian.

B2.5.3 Data endianness

SCTLR_EL1.E0E, configurable at EL1 or higher, determines the data endianness for execution at EL0.

The data size used for endianness conversions:

- Is the size of the data value that is loaded or stored for SIMD and floating-point register and general-purpose register loads and stores.
- Is the size of the data element that is loaded or stored for SIMD element and data structure loads and stores. For more information see *Endianness in SIMD operations*.

Instructions to reverse bytes in a general-purpose register or a SIMD and floating-point register

An application or device driver might have to interface to memory-mapped peripheral registers or shared memory structures that are not the same endianness as the internal data structures. Similarly, the endianness of the operating system might not match that of the peripheral registers or shared memory. In these cases, the PE requires an efficient method to transform explicitly the endianness of the data.

Table B2-1 shows the instructions that provide this functionality:

Table B2-1 Byte reversal instructions

Function	Instructions	Notes
Reverse bytes in 32-bit word or words[a]	REV32	For use with general-purpose registers
Reverse bytes in whole register	REV	For use with general-purpose registers
Reverse bytes in 16-bit halfwords	REV16	For use with general-purpose registers
Reverse elements in doublewords, vector	REV64	For use with SIMD and floating-point registers
Reverse elements in words, vector	REV32	For use with SIMD and floating-point registers
Reverse elements in halfwords, vector	REV16	For use with SIMD and floating-point registers

a. Can operate on multiple words.

Endianness in SIMD operations

SIMD element Load/Store instructions transfer vectors of elements between memory and the SIMD and floating-point register file. An instruction specifies both the length of the transfer and the size of the data elements being transferred. This information is used to load and store data correctly in both big-endian and little-endian systems.

For example:

```
LD1 {V0.4H}, [X1]
```

This loads a 64-bit register with four 16-bit values. The four elements appear in the register in array order, with the lowest indexed element fetched from the lowest address. The order of bytes in the elements depends on the endianness configuration, as shown in Figure B2-3. Therefore, the order of the elements in the registers is the same regardless of the endianness configuration.

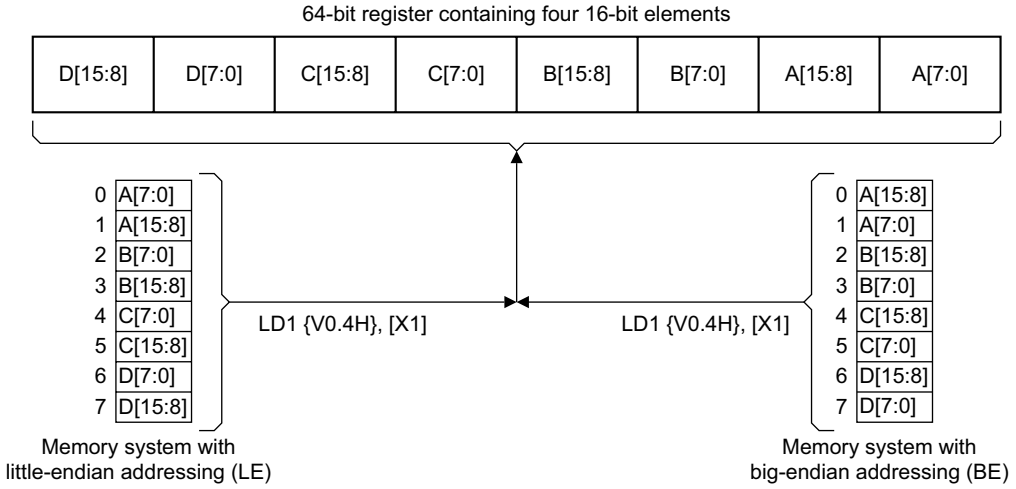

Figure B2-3 SIMD byte order example

The `BigEndian()` function determines the current endianness of the data:

```
boolean BigEndian();
```

The pseudocode function for `BigEndianReverse()` is as follows:

```
// BigEndianReverse()
// ==================

bits(width) BigEndianReverse (bits(width) value)
    assert width IN {8, 16, 32, 64, 128};
    integer half = width DIV 2;
    if width == 8 then return value;
    return BigEndianReverse(value<half-1:0>) : BigEndianReverse(value<width-1:half>);
```

B2.6 Atomicity in the ARM architecture

Atomicity is a feature of memory accesses, described as *atomic* accesses. The ARM architecture description refers to two types of atomicity, defined in:

- *Single-copy atomicity*.
- *Multi-copy atomicity* on page B2-80.

In the ARMv8 architecture, the atomicity requirements for memory accesses depends on the memory type, and whether the access is explicit or implicit. For more information, see:

- *Memory type overview* on page B2-69.
- *Requirements for single-copy atomicity*.
- *Requirements for multi-copy atomicity* on page B2-80.

B2.6.1 Single-copy atomicity

A read or write operation is *single-copy atomic* only if it meets the following conditions:

1. For a single-copy atomic store, if the store overlaps another single-copy atomic store, then all of the writes from one of the stores are inserted into the Coherence order of each overlapping byte before any of the writes of the other store are inserted into the Coherence orders of the overlapping bytes.

2. If a single-copy atomic load overlaps a single-copy atomic store and for any of the overlapping bytes the load returns the data written by the write inserted into the Coherence order of that byte by the single-copy atomic store then the load must return data from a point in the Coherence order no earlier than the writes inserted into the Coherence order by the single-copy atomic store of all of the overlapping bytes.

B2.6.2 Requirements for single-copy atomicity

For explicit memory accesses generated from an Exception level the following rules apply:

- All reads generated by load instructions that load a single general-purpose register and that are aligned to the size of the read in that instruction are single-copy atomic.

- All writes generated by store instructions that store a single general-purpose register and that are aligned to the size of the write in that instruction are single-copy atomic.

- Reads of general-purpose registers generated by Load Pair instructions that are aligned to the size of the load to each register are treated as two single-copy atomic reads, one for each register being loaded.

- Writes of general-purpose registers generated by Store pair instructions that are aligned to the size of the store of each register are treated as two single-copy atomic writes, one for each register being stored.

- Load-Exclusive Pair instructions of two 32-bit quantities and Store-Exclusive Pair instructions of 32-bit quantities are single-copy atomic.

- When the Store-Exclusive of a Load-Exclusive/Store-Exclusive pair instruction using two 64-bit quantities succeeds, it causes a single-copy atomic update of the entire memory location being updated.

  Note

  To atomically load two 64-bit quantities, perform a Load-Exclusive pair/Store-Exclusive pair sequence of reading and writing the same value for which the Store-Exclusive pair succeeds, and use the read values from the Load-Exclusive pair.

- Where translation table walks generate a read of a translation table entry, this read is single-copy atomic.

- For the atomicity of instruction fetches, see *Concurrent modification and execution of instructions* on page B2-80.

All other memory accesses are regarded as streams of accesses to bytes, and no atomicity between accesses to different bytes is ensured by the architecture.

All accesses to any byte are single-copy atomic.

Note

No memory accesses involving SIMD and floating-point registers, or memory accesses from a DC ZVA, have single-copy atomicity of any quantity greater than individual bytes.

If, according to these rules, an instruction is executed as a sequence of accesses, exceptions, including interrupts, can be taken during that sequence, regardless of the memory type being accessed. If any of these exceptions are returned from using their preferred return address, the instruction that generated the sequence of accesses is re-executed, and so any access performed before the exception was taken is repeated.

Note

The exception behavior for these multiple access instructions means they are not suitable for use for writes to memory for the purpose of software synchronization.

B2.6.3 Multi-copy atomicity

In a multiprocessing system, writes to a memory location are *multi-copy atomic* if the following conditions are both true:

- All writes to the same location are *serialized*, meaning they are observed in the same order by all observers, although some observers might not observe all of the writes.
- A read of a location does not return the value of a write until all observers observe that write.

Note

Writes that are not coherent are not multi-copy atomic.

B2.6.4 Requirements for multi-copy atomicity

In a multiprocessing system, coherent writes to a memory location are multi-copy atomic if the read of a location returns the value of a write only when all observers have observed that write.

For Normal memory, writes are not required to be multi-copy atomic.

For Device memory with the non-Gathering attribute, writes that are single-copy atomic are also multi-copy atomic.

For Device memory with the Gathering attribute, writes are not required to be multi-copy atomic.

B2.6.5 Concurrent modification and execution of instructions

The ARMv8 architecture limits the set of instructions that can be executed by one thread of execution as they are being modified by another thread of execution without requiring explicit synchronization.

Concurrent modification and execution of instructions can lead to the resulting instruction performing any behavior that can be achieved by executing any sequence of instructions that can be executed from the same Exception level, except where the instruction before modification and the instruction after modification is a `B`, `BL`, `NOP`, `BRK`, `SVC`, `HVC`, or `SMC` instruction.

For the `B`, `BL`, `NOP`, `BRK`, `SVC`, `HVC`, and `SMC` instructions the architecture guarantees that, after modification of the instruction, behavior is consistent with execution of either:

- The instruction originally fetched.
- A fetch of the modified instruction.

If one thread of execution changes a conditional branch instruction, such as B or BL, to another conditional instruction and the change affects both the condition field and the branch target, execution of the changed instruction by another thread of execution before the change is synchronized can lead to either:

- The old condition being associated with the new target address.
- The new condition being associated with the old target address.

These possibilities apply regardless of whether the condition, either before or after the change to the branch instruction, is the always condition.

For all other instructions, to avoid UNPREDICTABLE behavior, instruction modifications must be explicitly synchronized before they are executed. The required synchronization is as follows:

1. No PE must be executing an instruction when another PE is modifying that instruction.

2. To ensure that the modified instructions are observable, the PE that modified the instructions must issue the following sequence of instructions and operations:

```
; Coherency example for data and instruction accesses within the same Inner Shareable domain.
; Enter this code with <Wt> containing a new 32-bit instruction,
; to be held in Cacheable space at a location pointed to by Xn.
        STR Wt, [Xn]
        DC CVAU, Xn          ; Clean data cache by VA to point of unification (PoU)
        DSB ISH              ; Ensure visibility of the data cleaned from cache
        IC IVAU, Xn          ; Invalidate instruction cache by VA to PoU
        DSB ISH              ; Ensure completion of the invalidations
```

   Note

   The DC CVAU operation is not required if the area of memory is either Non-cacheable or Write-through Cacheable.

3. In a multiprocessor system, the IC IVAU is broadcast to all PEs within the Inner Shareable domain of the PE running this sequence. However, once the modified instructions are observable, each PE that is executing the modified instructions must issue the following instruction to ensure execution of the modified instructions:

```
ISB                              ; Synchronize fetched instruction stream
```

For more information about the required synchronization operation, see *Synchronization and coherency issues between data and instruction accesses* on page B2-73.

Note

For information about memory accesses caused by instruction fetches, see *Ordering requirements* on page B2-83.

B2.7 Memory ordering

This section describes observation ordering. It contains the following subsections:

- *Observability and completion*.
- *Ordering requirements* on page B2-83.
- *Memory barriers* on page B2-85.

For information on endpoint ordering of memory accesses, see *Reordering* on page B2-95.

In the ARMv8 memory model, the shareability memory attribute indicates whether hardware must ensure memory coherency.

The ARMv8 memory system architecture defines additional attributes and associated behaviors, defined in the system level section of this manual. See:

- Chapter D3 *The AArch64 System Level Memory Model*.
- Chapter D4 *The AArch64 Virtual Memory System Architecture*.

See also *Mismatched memory attributes* on page B2-97.

B2.7.1 Observability and completion

An *observer* is a master in the system that is capable of observing memory accesses. For a PE, the following mechanisms must be treated as independent observers:

- The mechanism that performs reads or writes to memory.
- A mechanism that causes an instruction cache to be filled from memory or that fetches instructions to be executed directly from memory. These are treated as reads.
- A mechanism that performs translation table walks. These are treated as reads.

The set of observers that can observe a memory access is defined by the system.

In the definitions in this subsection, *subsequent* means whichever of the following is appropriate to the context:

- After the point in time where the location is observed by that observer.
- After the point in time where the location is globally observed.

For all memory:

- A write to a location in memory is said to be *observed* by an observer when:
  - A subsequent read of the location by the same observer returns the value written by the observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the observed write.
  - A subsequent write of the location by the same observer is sequenced in the *Coherence order* of the location after the observed write.
- A write to a location in memory is said to be *globally observed* for a shareability domain or set of observers when:
  - A subsequent read of the location by any observer in that shareability domain returns the value written by the globally observed write, or written by a write to that location by any observer that is sequenced in the *Coherence order* of the location after the globally observed write.
  - A subsequent write of the location by any observer in that shareability domain is sequenced in the *Coherence order* of the location after the globally observed write.
- A read of a location in memory is said to be observed by an observer when a subsequent write to the location by the same observer has no effect on the value returned by the read.
- A read of a location in memory is said to be globally observed for a shareability domain when a subsequent write to the location by any observer in that shareability domain has no effect on the value returned by the read.

Additionally, for Device-nGnRnE memory:

- A read or write of a memory-mapped location in a peripheral that exhibits side-effects is said to be observed, and globally observed, only when the read or write:
  - Meets the general conditions listed.
  - Can begin to affect the state of the memory-mapped peripheral.
  - Can trigger all associated side-effects, whether they affect other peripheral devices, PEs, or memory.

  Note

  This definition is consistent with the memory access having reached the peripheral.

For all memory, the completion rules are defined as:

- A read or write is complete for a shareability domain when all of the following are true:
  - The read or write is globally observed for that shareability domain.
  - Any translation table walks associated with the read or write are complete for that shareability domain.
- A translation table walk is complete for a shareability domain when the memory accesses associated with the translation table walk are globally observed for that shareability domain, and the TLB is updated.
- A cache or TLB maintenance instruction is complete for a shareability domain when the effects of the instruction are globally observed for that shareability domain, and any translation table walks that arise from the instruction are complete for that shareability domain.

  The completion of any cache or TLB maintenance instruction includes its completion on all PEs that are affected by both the instruction and the `DSB` operation that is required to guarantee visibility of the maintenance instruction.

Completion of side-effects of accesses to Device memory

The completion of a memory access to Device memory other than Device-nGnRnE is not guaranteed to be sufficient to determine that the side-effects of the memory access are visible to all observers. The mechanism that ensures the visibility of side-effects of a memory access is IMPLEMENTATION DEFINED.

B2.7.2 Ordering requirements

ARMv8 defines restrictions for the permitted ordering of memory accesses. These restrictions depend on the memory locations that are being accessed. See *Memory types and attributes* on page B2-89.

The following additional restrictions apply to the order in which accesses to Normal memory are observed:

- Reads and writes can be observed in any order provided the following constraints are met:
  - If an address dependency exists between two reads or between a read and a write, then those memory accesses are observed in program order by all observers within the shareability domain of the memory address being accessed.

    The ARMv8 architecture relaxes this rule for execution where the second read is generated by a Load Non-Temporal Pair instruction. See *Load/Store Non-temporal Pair* on page C3-134 and *Load/Store SIMD and Floating-point Non-temporal pair* on page C3-138.
  - Writes that would not occur in a simple sequential execution of the program cannot be observed by other observers. This implies that where a control, address or data dependency exists between a read and a write, those memory accesses are observed in program order by all observers within the shareability domain of the memory addresses being accessed.
  - Ordering can be achieved by using a `DMB` or `DSB` barrier. For more information on `DMB` and `DSB` instructions, see *Memory barriers* on page B2-85.
- Reads and writes to the same location are coherent within the shareability domain of the memory address being accessed.

- Two reads of the same location by the same observer are observed in program order by all observers within the shareability domain of the memory address being accessed.
- Writes are not required to be multi-copy atomic. This means that in the absence of barriers, the observation of a store by one observer does not imply the observation of the store by another observer.
- Instructions that access multiple elements have no defined ordering requirements for the memory accesses relative to each other.

Memory accesses caused by instruction fetches are not required to be observed in program order, unless they are separated by an `ISB` or other context synchronization event.

Address dependencies and order

In the ARMv8 architecture, a register data dependency creates order between a load instruction and a subsequent memory transaction, that is between the data value returned from the load and the address used by the subsequent memory transaction.

A register data dependency exists between a first data value and a second data value exists when either:

- The register, excluding the zero register (XZR or WZR), used to hold the first data value is used in the calculation of the second data value, and the calculation between the first data value and the second data value does not consist of either:
  - A conditional branch whose condition is determined by the first data value.
  - A conditional selection, move, or computation whose condition is determined by the first data value, where the input data values for the selection, move, or computation do not have a data dependency on the first data value.
- There is a register data dependency between the first data value and a third data value, and between the third data value and the second data value.

Note

A register data dependency can exist even if the value of the first data value is discarded as part of the calculation, as might be the case if it is ANDed with `0x0` or if arithmetic using the first data value cancels out its contribution.

For example, each of the following code sequences creates order between the memory transactions:

Sequence 1
```
LDR X1, [X2]
AND X1, X1, XZR
LDR X4, [X3, X1]
```

Sequence 2
```
LDR X1, [X2]
ADD X3, X3, X1
SUB X3, X3, X1
STR X4, [X3]
```

Address dependencies of Load Non-temporal Pair instructions

Where an address dependency exists between two reads, and the second read was generated by a Load Non-temporal Pair instruction, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by other observers within the shareability domain of the memory addresses being accessed.

This affects the following instruction:

- *LDNP* on page C6-504.

B2.7.3 Memory barriers

The ARM architecture is a weakly ordered memory architecture that supports out of order completion. *Memory barrier* is the general term applied to an instruction, or sequence of instructions, that forces synchronization events by a PE with respect to retiring Load/Store instructions. The memory barriers defined by the ARMv8 architecture provide a range of functionality, including:

- Ordering of Load/Store instructions.
- Completion of Load/Store instructions.
- Context synchronization.

The following subsections describe the ARMv8 memory barrier instructions:

- *Instruction Synchronization Barrier (ISB)*
- *Data Memory Barrier (DMB)*.
- *Data Synchronization Barrier (DSB)* on page B2-86.
- *Shareability and access limitations on the data barrier operations* on page B2-87.
- *Load-Acquire, Store-Release* on page B2-87.

Note

Depending on the required synchronization, a program might use memory barriers on their own, or it might use them in conjunction with cache maintenance and memory management instructions that in general are only available when software execution is at EL1 or higher.

The `DMB` and `DSB` memory barriers affect reads and writes to the memory system generated by Load/Store instructions and data or unified cache maintenance instructions being executed by the PE. Instruction fetches or accesses caused by a hardware translation table access are not explicit accesses.

Instruction Synchronization Barrier (ISB)

An `ISB` instruction flushes the pipeline in the PE, so that all instructions that come after the `ISB` instruction in program order are fetched from the cache or memory only after the `ISB` instruction has completed. Using an `ISB` ensures that the effects of context-changing operations executed before the `ISB` are visible to the instructions fetched after the `ISB` instruction. Examples of context-changing operations that require the insertion of an `ISB` instruction to ensure the effects of the operation are visible to instructions fetched after the `ISB` instruction are:

- Completed cache and TLB maintenance instructions.
- Changes to system control registers.

Any context-changing operations appearing in program order after the `ISB` instruction only take effect after the `ISB` has been executed.

```
InstructionSynchronizationBarrier();
```

See also *Memory barriers* on page D3-1630.

Data Memory Barrier (DMB)

The `DMB` instruction is a data memory barrier. The PE that executes the `DMB` instruction is referred to as the executing PE, PEe. The `DMB` instruction takes the *required shareability domain* and *required access types* as arguments:

```
DataMemoryBarrier(MBReqDomain domain, MBReqTypes types);
```

See *Shareability and access limitations on the data barrier operations* on page B2-87.

If the required shareability is *Full system* then the operation applies to all observers within the system.

A `DMB` creates two groups of memory accesses, Group A and Group B:

Group A Contains:

- All explicit memory accesses of the required access types from observers in the same required shareability domain as PEe that are observed by PEe before the `DMB` instruction. These accesses include any accesses of the required access types performed by PEe.

- All loads of required access types from an observer PEx in the same required shareability domain as PEe that have been observed by any given different observer, PEy, in the same required shareability domain as PEe before PEy has performed a memory access that is a member of Group A.

Group B Contains:

- All explicit memory accesses of the required access types by PEe that occur in program order after the `DMB` instruction.
- All explicit memory accesses of the required access types by any given observer PEx in the same required shareability domain as PEe that can only occur after a load by PEx has returned the result of a store that is a member of Group B.

Any observer with the same required shareability domain as PEe observes all members of Group A before it observes any member of Group B to the extent that those group members are required to be observed, as determined by the shareability and cacheability of the memory locations accessed by the group members.

If members of Group A and members of Group B access the same memory-mapped peripheral of arbitrary system-defined size, then members of Group A that are accessing Device or Normal Non-cacheable memory arrive at that peripheral before members of Group B that are accessing Device or Normal Non-cacheable memory. Where the members of Group A and Group B that must be ordered are from the same PE, a `DMB NSH` is sufficient for this guarantee.

Note

- A memory access might be in neither Group A nor Group B. The `DMB` does not affect the order of observation of such a memory access.
- The second part of the definition of Group A is recursive. Ultimately, membership of Group A derives from the observation by PEy of a load before PEy performs an access that is a member of Group A as a result of the first part of the definition of Group A.
- The second part of the definition of Group B is recursive. Ultimately, membership of Group B derives from the observation by any observer of an access by PEe that is a member of Group B as a result of the first part of the definition of Group B.

`DMB` only affects memory accesses and the operation of data cache and unified cache maintenance instructions, see *Cache maintenance instructions* on page D3-1608. It has no effect on the ordering of any other instructions executing on the PE.

See also *Memory barriers* on page D3-1630.

Data Synchronization Barrier (DSB)

The `DSB` instruction is a special memory barrier, that synchronizes the execution stream with memory accesses.

The `DSB` instruction takes the *required shareability domain* and *required access types* as arguments:

```
DataSynchronizationBarrier(MBReqDomain domain, MBReqTypes types);
```

See *Shareability and access limitations on the data barrier operations* on page B2-87.

If the required shareability is *Full system* then the operation applies to all observers within the system.

A `DSB` behaves as a `DMB` with the same arguments, and also has the additional properties defined in this section. The PE that executes the `DSB` instruction is referred to as the executing PE, PEe

A `DSB` completes when all of the following apply:

- All explicit memory accesses that are observed by PEe before the `DSB` is executed and are of the required access types, and are from observers in the same required shareability domain as PEe, are complete for the set of observers in the required shareability domain.

- All cache maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.
- If the required access types of the DSB is *reads and writes*, all TLB maintenance instructions issued by PEe before the DSB are complete for the required shareability domain.

In addition, no instruction that appears in program order after the DSB instruction can execute until the DSB completes.

See also *Memory barriers* on page D3-1630.

Shareability and access limitations on the data barrier operations

The DMB and DSB instructions can each take an optional limitation argument that specifies:

- The shareability domain over which the instruction must operate. This is one of:
  - Full system.
  - Outer Shareable.
  - Inner Shareable.
  - Non-shareable.
- The accesses for which the instruction operates. This is one of:
  - Read and write accesses in Group A and Group B.
  - Write accesses only in Group A and Group B.
  - Read access only in Group A and read and write accesses in Group B.

    Note

    This is occasionally referred to as a Load-Load/Store barrier.

If no specifiers are used then each instruction operates for read and write accesses, over the full system. See the instruction descriptions for more information about these arguments.

Note

ISB also supports an optional limitation argument that can only contain one value that corresponds to full system operation.

Load-Acquire, Store-Release

ARMv8 provides a set of instructions with Acquire semantics for loads, and Release semantics for stores. See *Load-Acquire/Store-Release* on page C3-136.

For all memory types, these instructions have the following ordering requirements:

- A Store-Release followed by a Load-Acquire is observed in program order by each observer within the common shareability domain of both:
  - The memory address being accessed by the Store-Release.
  - The memory address being accessed by the Load-Acquire.
- A Load-Acquire is a read that must be observed by all observers in the shareability domain of the accessed memory location before any other read or write that both:
  - Is caused by an instruction that appears in program order after the Load-Acquire.
  - Accesses memory in the shareability domain accessed by the Load-Acquire.
- A Load-Acquire places no additional ordering constraints on any loads or stores appearing before the Load-Acquire.

- Store-Release is a write where, for each observer within the shareability domain of the memory address being accessed by the Store-Release:
  - The reads and writes generated by loads and stores appearing in program order before the Store-Release are observed, as required by the shareability domains of the memory addresses being accessed by those loads and stores, before that observer observes the write generated by the Store-Release.
  - Any writes that have been observed before the Store-Release by the PE that executes the Store-Release are observed, as required by the shareability domains of the memory addresses being accessed by those stores, before that observer observes the write generated by the Store-Release.
- The Store-Release places no additional ordering constraints on any loads or stores appearing after the Store-Release instruction.
- All Store-Release instructions must be multi-copy atomic when they are observed with Load-Acquire instructions. This means that if one observer has seen the Store-Release, then all observers in the common shareability domain have seen the Store-Release.

In addition, for accesses to a memory-mapped peripheral of an arbitrary system-defined size that is defined using Device memory, these instructions have the following requirements:

- A Load-Acquire to an address in the memory-mapped peripheral will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed after the Load-Acquire will arrive at the memory-mapped peripheral after the memory access of the Load-Acquire.
- A Store-Release to an address in the memory-mapped peripheral will ensure that all memory accesses using Device memory types to the same memory-mapped peripheral that are architecturally required to be observed before the Store-Release will arrive at the memory-mapped peripheral before the memory access of the Store-Release.
- Any memory access to the memory-mapped peripheral that are architecturally required to be ordered before the memory access of a Store-Release will arrive at the memory-mapped peripheral before any memory access to the same memory-mapped peripheral that are architecturally required to be ordered after the memory access of a Load-Acquire to the same memory location as the Store-Release, where the Load-Acquire has observed the value stored by the Store-Release.

Load-Acquire and Store-Release, other than Load-Acquire Exclusive Pair and Store-Release-Exclusive Pair, access only a single data element. This access is single-copy atomic. The address of the data object must be aligned to the size of the data element being accessed, otherwise the access generates an Alignment fault.

Load-Acquire Exclusive Pair and Store-Release Exclusive Pair access two data elements. The address supplied to the instructions must be aligned to twice the size of the element being loaded, otherwise the access generates an Alignment fault.

A Store-Release Exclusive instruction only has the release semantics if the store is successful.

Note

- Each Load-Acquire Exclusive and Store-Release Exclusive instruction is essentially a variant of the equivalent Load-Exclusive or Store-Exclusive instruction. All usage restrictions and single-copy atomicity properties:
  - That apply to the Load-Exclusive instructions also apply to the Load-Acquire Exclusive instructions.
  - That apply to the Store-Exclusive instructions also apply to the Store-Release Exclusive instructions.
- The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction.

B2.8 Memory types and attributes

In ARMv8 the ordering of accesses for locations of memory, referred to as the memory order model, is defined by the memory attributes. The following sections describe this model:

- *Normal memory*.
- *Device memory* on page B2-91.
- *Memory access restrictions* on page B2-96.

B2.8.1 Normal memory

The Normal memory type attribute applies to most memory in a system. It indicates that the hardware might perform speculative data read accesses to these locations.

The Normal memory type has the following properties:

- A write to a memory location with the Normal attribute completes in finite time. This means that it is globally observed for the shareability domain of the memory location in finite time. For a Non-cacheable location, the location is observed by all observers in finite time.
- A completed write to a memory location with the Normal attribute is globally observed for the shareability domain of the memory location in finite time without the need for explicit cache maintenance instructions or barriers. For a Non-cacheable location, the completed write is globally observed for all observers in finite time without the need for explicit cache maintenance instructions or barriers.
- Writes to a memory location with the Normal memory attribute that are Non-cacheable must reach the endpoint for that location in the memory system in finite time.
- Unaligned memory accesses can access Normal memory if the system is configured to generate such accesses.
- There is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Normal memory* on page B2-91.

Note

- The Normal memory attribute is appropriate for locations of memory that are idempotent, meaning that they exhibit all of the following properties:
  - Read accesses can be repeated with no side-effects.
  - Repeated read accesses return the last value written to the resource being read.
  - Read accesses can fetch additional memory locations with no side-effects.
  - Write accesses can be repeated with no side-effects if the contents of the location accessed are unchanged between the repeated writes or as the result of an exception, as described in this section.
  - Unaligned accesses can be supported.
  - Accesses can be merged before accessing the target memory system.
- An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page B2-79 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated write accesses to a location that has been changed between the write accesses.

The following sections describe the other attributes for Normal memory:

- *Shareable Normal memory* on page B2-90.
- *Non-shareable Normal memory* on page B2-91.

See also:

- *Atomicity in the ARM architecture* on page B2-79.
- *Memory barriers* on page B2-85. For accesses to Normal memory, a `DMB` instruction is required to ensure the required ordering.
- *Concurrent modification and execution of instructions* on page B2-80.

Shareable Normal memory

A Normal memory location has a Shareability attribute that is:

- Defined independently for the Inner Shareable and Outer Shareable shareability domains.
- Defined, for each shareability domain, as being either Shareable or Non-shareable.

The shareability attributes define the data coherency requirements of the location, that hardware must enforce. They do not affect the coherency requirements of instruction fetches, see *Synchronization and coherency issues between data and instruction accesses* on page B2-73.

Note

- System designers can use the shareability attribute to specify the locations in Normal memory for which coherency must be maintained. However, software developers must not assume that specifying a memory location as Non-shareable permits software to make assumptions about the incoherency of the location between different PEs in a shared memory system. Such assumptions are not portable between different multiprocessing implementations that might use the shareability attribute. Any multiprocessing implementation might implement caches that are shared, inherently, between different processing elements.
- This architecture assumes that all PEs that use the same operating system or hypervisor are in the same Inner Shareable shareability domain.

Shareable, Inner Shareable, and Outer Shareable Normal memory

The ARM architecture abstracts the system as a series of Inner and Outer Shareability domains.

Each Inner Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Inner Shareable attribute made by any member of that set.

Each Outer Shareability domain contains a set of observers that are data coherent for each member of that set for data accesses with the Outer Shareable attribute made by any member of that set.

The following properties also hold:

- Each observer is only a member of a single Inner Shareability domain.
- Each observer is only a member of a single Outer Shareability domain.
- All observers in an Inner Shareability domain are always members of the same Outer Shareability domain. This means that an Inner Shareability domain is a subset of an Outer Shareability domain, although it is not required to be a proper subset.

Note

- Because all data accesses to Non-cacheable locations are data coherent to all observers, Non-cacheable locations are always treated as Outer Shareable.
- The Inner Shareable domain is expected to be the set of PEs controlled by a single hypervisor or operating system.

The details of the use of the shareability attributes are system-specific. Example B2-1 shows how they might be used.

Example B2-1 Use of shareability attributes

In an implementation, a particular subsystem with two clusters of PEs has the requirement that:

- In each cluster, the data caches or unified caches of the PEs in the cluster are transparent for all data accesses to memory locations with the Inner Shareable attribute.
- However, between the two clusters, the caches:
  - Are not required to be coherent for data accesses that have only the Inner Shareable attribute.
  - Are coherent for data accesses that have the Outer Shareable attribute.

In this system, each cluster is in a different shareability domain for the Inner Shareable attribute, but all components of the subsystem are in the same shareability domain for the Outer Shareable attribute.

A system might implement two such subsystems. If the data caches or unified caches of one subsystem are not transparent to the accesses from the other subsystem, this system has two Outer Shareable shareability domains.

Having two levels of shareability means system designers can reduce the performance and power overhead for shared memory locations that do not need to be part of the Outer Shareable shareability domain.

For Shareable Normal memory, the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer in the same Shareability domain.

Non-shareable Normal memory

For Normal memory locations, the Non-shareable attribute identifies Normal memory that is likely to be accessed only by a single PE.

A location in Normal memory with the Non-shareable attribute does not require the hardware to make data accesses by different observers coherent, unless the memory is Non-cacheable. For a Non-shareable location, if other observers share the memory system, software must use cache maintenance instructions, if the presence of caches might lead to coherency issues when communicating between the observers. This cache maintenance requirement is in addition to the barrier operations that are required to ensure memory ordering.

For Non-shareable Normal memory, it is IMPLEMENTATION DEFINED whether the Load-Exclusive and Store-Exclusive synchronization primitives take account of the possibility of accesses by more than one observer.

Multi-register loads and stores that access Normal memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture.

For all instructions that load or store one or more SIMD and floating-point register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions.

B2.8.2 Device memory

The Device memory type attributes define memory locations where an access to the location can cause side-effects, or where the value returned for a load can vary depending on the number of loads performed. Typically, the Device memory attributes are used for memory-mapped peripherals and similar locations.

The attributes for ARMv8 Device memory are:

Gathering Identified as G or nG, see *Gathering* on page B2-94.

Reordering Identified as R or nR, see *Reordering* on page B2-95.

Early Write Acknowledgement hint

Identified as E or nE, see *Early Write Acknowledgement* on page B2-95.

The ARMv8 Device memory types are:

Device-nGnRnE Device non-Gathering, non-Reordering, No Early write acknowledgement.

Equivalent to the Strongly-ordered memory type in earlier versions of the architecture.

Device-nGnRE Device non-Gathering, non-Reordering, Early Write Acknowledgement.

Equivalent to the Device memory type in earlier versions of the architecture.

Device-nGRE Device non-Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. The use of barriers is required to order accesses to Device-nGRE memory.

Device-GRE Device Gathering, Reordering, Early Write Acknowledgement.

ARMv8 adds this memory type to the translation table formats found in earlier versions of the architecture. Device-GRE memory has the fewest constraints. It behaves similar to Normal memory, with the restriction that speculative accesses to Device-GRE memory is forbidden.

Collectively these are referred to as *any Device memory type*. Going down the list, the memory types are described as getting *weaker*; conversely the going up the list the memory types are described as getting *stronger*.

Note

- As the list of types shows, these additional attributes are hierarchical. For example, a memory location that permits Gathering must also permit Reordering and Early Write Acknowledgement.
- The architecture does not require an implementation to distinguish between each of these memory types and ARM recognizes that not all implementations will do so. The subsection that describes each of the attributes, describes the implementation rules for the attribute.
- Earlier versions of the ARM architecture defined the following memory types:
  - Strongly-ordered memory. This is the equivalent of the Device-nGnRnE memory type.
  - Device memory. This is the equivalent of the Device-nGnRE memory type.

All of these memory types have the following properties:

- Speculative data accesses are not permitted to any memory location with any Device memory attribute. This means that each memory access to any Device memory type must be one that would be generated by a simple sequential execution of the program.

  Three exceptions to this apply:

  - Reads generated by the SIMD and floating-point instructions can access bytes that are not explicitly accessed by the instruction if the bytes accessed are in a 16-byte window, aligned to 16-bytes, that contains at least one byte that is explicitly accessed by the instruction.
  - For Device memory with the Gathering attribute, reads generated by the `LDNP` instructions are permitted to access bytes that are not explicitly accessed by the instruction, provided that the bytes accessed are in a 128-byte window, aligned to 128-bytes, that contains at least one byte that is explicitly accessed by the instruction.

— Where a load or store instruction performs a sequence of memory accesses, as opposed to one single-copy atomic access as defined in the rules for single-copy atomicity, these accesses might occur multiple times as a result of executing the load or store instruction. See *Single-copy atomicity* on page B2-79.

Note

— An instruction that generates a sequence of accesses as described in *Atomicity in the ARM architecture* on page B2-79 might be abandoned as a result of an exception being taken during the sequence of accesses. On return from the exception the instruction is restarted, and therefore one or more of the memory locations might be accessed multiple times. This can result in repeated accesses to a location where the program only defines a single access. For this reason, ARM strongly recommends that no accesses to Device memory are performed from a single instruction that spans the boundary of a translation granule or which in some other way could lead to some of the accesses being aborted.

— Write speculation that is visible to other observers is prohibited for all memory types.

- A write to a memory location with any Device memory attribute completes in finite time. This means that it is globally observed for all observers in the system in finite time.
- If a location with any Device memory attribute changes without an explicit write by an observer, this change must also be globally observed for all observers in the system in finite time. Such a change might occur in a peripheral location that holds status information.
- A completed write to a memory location with any Device memory attribute is globally observed for all observers in finite time without the need for explicit maintenance.
- Data accesses to memory locations are coherent for all observers in the system, and correspondingly are treated as being Outer Shareable.
- A memory location with any Device memory attribute cannot be allocated into a cache.
- Writes to a memory location with any Device memory attribute must reach the endpoint for that address in the memory system in finite time. Typically, the endpoint is a peripheral or some physical memory.
- All accesses to memory with any Device memory attribute must be aligned. Any unaligned access generates an Alignment fault at the first stage of translation that defined the location as being Device.

  Note

  In the Non-secure EL1 translation regime in systems where HCR_EL2.TGE == 1 and HCR_EL2.DC == 0, any Alignment fault that results from the fact that all locations are treated as Device is a fault at the first stage of translation. This causes ESR_EL2.ISS.[24] to be 0.

- Hardware does not prevent speculative instruction fetches from a memory location with any of the Device memory attributes unless the memory location is also marked as Execute-never for all Exception levels.

  Note

  This means that to prevent speculative instruction fetches from memory locations with Device memory attributes, any location that is assigned any Device memory type must also be marked as Execute-never for all Exception levels. Failure to mark a memory location with any Device memory attribute as Execute-never for all Exception levels is a programming error.

For instruction fetches, if branches cause the program counter to point to an area of memory with the Device attribute which is not marked as Execute-never for the current Exception level, an implementation can either:

- Treat the instruction fetch as if it were to a memory location with the Normal Non-cacheable attribute.
- Take a Permission fault.

Gathering

In the Device memory attribute:

G Indicates that the location has the Gathering attribute.

nG Indicates that the location does not have the Gathering attribute, meaning it is non-Gathering.

The Gathering attribute determines whether it is permissible for either:

- Multiple memory accesses of the same type, read or write, to the same memory location to be merged into a single transaction.
- Multiple memory accesses of the same type, read or write, to different memory locations to be merged into a single memory transaction on an interconnect.

Note

This also applies to writebacks from the cache, whether caused by a *Natural eviction* or as a result of a cache maintenance instruction.

For memory types with the Gathering attribute, either of these behaviors is permitted, provided that the ordering and coherency rules of the memory location are followed.

For memory types with the non-Gathering attribute, neither of these behaviors is permitted. As a result:

- The number of memory accesses that are made corresponds to the number that would be generated by a simple sequential execution of the program.
- All access occur at their programmed size, except that there is no requirement for the memory system beyond the PE to be able to identify the elements accessed by multi-register Load/Store instructions. See *Multi-register loads and stores that access Device memory* on page B2-96.

Gathering between memory accesses separated by a memory barrier that affects those memory accesses is not permitted. This applies if one memory access is in Group A and one memory access is in Group B. That is, gathering is not permitted between a memory access in Group A and a memory access in Group B if the two accesses are separated by a barrier that affects at least one of the accesses.

Gathering between two memory accesses generated by a Load-Acquire/Store-Release is not permitted.

A read from a memory location with the non-Gathering attribute cannot come from a cache or a buffer, but must come from the endpoint for that address in the memory system. Typically this is a peripheral or physical memory.

Note

- A read from a memory location with the Gathering attribute can come from intermediate buffering of a previous write, provided that:
  - The accesses are not separated by a `DMB` or `DSB` barrier that affects both of the accesses, for example if one access is in Group A and the other is in Group B.
  - The accesses are not separated by other ordering constructions that require that the accesses are in order. Such a construction might be a combination of Load-Acquire and Store-Release.
  - The accesses are not generated by a Store-Release instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, gathering can be performed if a programmer cannot tell whether gathering has occurred.

An implementation is permitted to perform an access with the Gathering attribute in a manner consistent with the requirements specified by the Non-gathering attribute.

An implementation is not permitted to perform an access with the Non-gathering attribute in a manner consistent with the relaxations allowed by the Gathering attribute.

Reordering

In the Device memory attribute:

R Indicates that the location has the Reordering attribute.

nR Indicates that the location does not have the Reordering attribute, meaning it is non-Reordering.

For all memory types with the non-Reordering attribute, the order of memory accesses arriving at a single peripheral of IMPLEMENTATION DEFINED size, as defined by the peripheral, must be the same order that occurs in a simple sequential execution of the program.That is, the accesses appear in program order. This ordering applies to all accesses using any of the memory types with the non-Reordering attribute. As a result, if there is a mixture of Device-nGnRE and Device-nGnRnE accesses to the same peripheral, these occur in program order. If the memory accesses are not to a peripheral, then this attribute imposes no restrictions.

Note

- The IMPLEMENTATION DEFINED size of the single peripheral is the same as applies for the ordering guarantee provided by the `DMB` instruction.
- The ARM architecture only defines programmer visible behavior. Therefore, reordering can be performed if a programmer cannot tell whether reordering has occurred.

An implementation is permitted to perform an access with the Reordering attribute in a manner consistent with the requirements specified by the non-Reordering attribute.

An additional relaxation is that an implementation is not permitted to perform an access with the non-Reordering attribute in a manner consistent with the relaxations allowed by the Reordering attribute.

The non-Reordering attribute does not require any additional ordering, other than that which applies to Normal memory, between:

- Accesses with the non-Reordering attribute and accesses with the Reordering attribute.
- Accesses with the non-Reordering attribute and accesses to Normal memory.
- Accesses with the non-Reordering attribute and accesses to different peripherals of IMPLEMENTATION DEFINED size.

The non-Reordering attribute has no effect on the ordering of cache maintenance instructions, even if the memory location specified in the instruction has the non-Reordering attribute.

Early Write Acknowledgement

In the Device memory attribute:

E Indicates that the location has the Early Write Acknowledgement attribute.

nE Indicates that the location has the No Early Write Acknowledgement attribute.

Early Write Acknowledgement is a hint to the platform memory system. Assigning the No Early Write Acknowledgement attribute to a Device memory location recommends that only the endpoint of the write access returns a write acknowledgement of the access, and that no earlier point in the memory system returns a write acknowledge. This means that a `DSB` barrier, executed by the PE that performed the write to the No Early Write Acknowledgement location, completes only after the write has reached its endpoint in the memory system. Typically, this endpoint is a peripheral or physical memory.

When the Early Write Acknowledgement attribute is assigned to a Device memory location, there is no such recommendation for the handling of accesses to that location.

Note

- The Early Write Acknowledgement hint has no effect on the ordering rules. The purpose of signalling no Early Write Acknowledgement is to signal to the interconnect that the peripheral requires the ability to signal the acknowledgement. The No Write Acknowledgement signal also provides an additional semantic that can be interpreted by the driver that is accessing the peripheral.

- This attribute is treated as a hint, as the exact nature of the interconnects accessed by a PE is outside the scope of the ARM architecture definition, and not all interconnects provide a mechanism to ensure that a write has reached the physical endpoint of the memory system.
- ARM recommends that writes with the No Early Write Acknowledgement hint are used for PCIe configuration writes. However, the mechanisms by which PCIe configuration writes are identified are IMPLEMENTATION DEFINED.
- ARM strongly recommends that the Early Write Acknowledgement hint is not ignored by a PE, but is made available for use by the system.

Because the No Early Write Acknowledgement attribute is a hint:

- An implementation is permitted to perform an access with the Early Write Acknowledgement attribute in a manner consistent with the requirements specified by the No Early Write Acknowledgement attribute.
- An implementation is permitted to perform an access with the No Early Write Acknowledgement attribute in a manner consistent with the relaxations allowed by the Early Write Acknowledgement attribute.

Multi-register loads and stores that access Device memory

For all instructions that load or store more than one general-purpose register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the elements accessed by these load or store instructions.

For all instructions that load or store more than one general-purpose register from an Exception level the order in which the registers are accessed is not defined by the architecture. This applies even to accesses to any type of Device memory.

For all instructions that load or store one or more floating-point and SIMD register from an Exception level there is no requirement for the memory system beyond the PE to be able to identify the size of the element accessed by these load or store instructions, even for access to any type of Device memory.

B2.8.3 Memory access restrictions

The following restrictions apply to memory accesses:

- For accesses to any two bytes, *p* and *q*, that are generated by the same instruction:
  - The bytes *p* and *q* must have the same memory type and shareability attributes, otherwise the results are CONSTRAINED UNPREDICTABLE. For example, an `LD1`, `ST1`, or an unaligned load or store that spans the boundary between Normal memory and Device memory is CONSTRAINED UNPREDICTABLE.
  - Except for possible differences in the cache allocation hints, ARM deprecates having different cacheability attributes for bytes *p* and *q*.
- An instruction that causes multiple accesses to Device memory must not cross a 4KB address boundary, otherwise the effect is constrained unpredictable. For this reason, it is important than an access to a volatile memory device is not made using a single instruction that crosses a 4KB address boundary.

  ARM expects this restriction to impose constraints on the placing of volatile memory devices in the memory map of a system, rather than expecting a compiler to be aware of the alignment of memory accesses.

B2.9 Mismatched memory attributes

Memory attributes are controlled by privileged software. For more information, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

Physical memory locations are accessed with *mismatched attributes* if all accesses to the location do not use a common definition of all of the following attributes of that location:

- Memory type, Device or Normal.
- Shareability.
- Cacheability, for the same level of the inner or outer cache, but excluding any cache allocation hints.

Collectively these are referred to as memory attributes.

Note

The terms *location* and *memory location* refer to any byte within the current coherency granule and are used interchangeably.

The following rules apply when a physical memory location is accessed with mismatched attributes:

1. When a memory location is accessed with mismatched attributes the only software visible effects are one or more of the following:
   - Uniprocessor semantics for reads and writes to that memory location might be lost. This means:
     - A read of the memory location by one agent might not return the value most recently written to that memory location by the same agent.
     - Multiple writes to the memory location by one agent with different memory attributes might not be ordered in program order.
   - There might be a loss of coherency when multiple agents attempt to access a memory location.
   - There might be a loss of properties derived from the memory type, as described in later bullets in this section.
   - If all Load-Exclusive/Store-Exclusive instructions executed across all threads to access a given memory location do not use consistent memory attributes, the exclusive monitor state becomes UNKNOWN.
   - Bytes written without the Write-Back cacheable attribute within the same Write-Back granule as bytes written with the Write-Back cacheable attribute might have their values reverted to the old values as a result of cache Write-Back.
2. The loss of properties associated with mismatched memory type attributes refers only to the following properties of Device memory that are additional to the properties of Normal memory:
   - Prohibition of speculative read accesses.
   - Prohibition on Gathering.
   - Prohibition on Re-ordering.
   - The Write Acknowledgement guarantee with respect to the endpoint of the access.

   If the only memory type mismatch associated with a memory location across all users of the memory location is between different types of Device memory, then all accesses might take the properties of the weakest Device memory type.
3. If all aliases of a memory location that permit write access to the location assign the same shareability and cacheability attributes to that location, and all these aliases use a definition of the shareability attribute that includes all the threads of execution that can access the location, then any agent that reads the memory location using these shareability and cacheability attributes accesses it coherently, to the extent required by that common definition of the memory attributes.
4. The possible loss of software-visible effects caused by mismatched attributes for a memory location are defined more precisely if all of the mismatched attributes define the memory location as one of:
   - Any Device memory type.
   - Normal Inner Non-cacheable, Outer Non-cacheable memory.

In these cases, the only permitted software-visible effects of the mismatched attributes are one or more of the following:

- Possible loss of properties described in point 2 page B2-97, derived from the memory type when multiple agents attempt to access the memory location.
- Possible reordering of memory transactions to the memory location with different memory attributes, potentially leading to a loss of coherency or uniprocessor semantics. Any possible loss of coherency or uniprocessor semantics can be avoided by inserting `DMB` barrier instructions between accesses to the same memory location that might use different attributes.

5. If the mismatched attributes for a memory location all assign the same shareability attribute to the location, any loss of uniprocessor semantics or coherency within a shareability domain can be avoided by use of software cache management. To do so, software must use the techniques that are required for the software management of the coherency of cacheable locations between agents a in different shareability domains. This means:
   - Before writing to a location not using the Write-Back attribute, software must invalidate, or clean, a location from the caches if any agent might have written to the location with the Write-Back attribute. This avoids the possibility of overwriting the location with stale data.
   - After writing to a location with the Write-Back attribute, software must clean the location from the caches, to make the write visible to external memory.
   - Before reading the location with a cacheable attribute, software must invalidate the location from the caches, to ensure that any value held in the caches reflects the last value made visible in external memory.

   In all cases:
   - Location refers to any byte within the current coherency granule.
   - A clean and invalidate instruction can be used instead of a clean instruction, or instead of an invalidate instruction.
   - In the sequences outlined in this section, all cache maintenance instructions and memory transactions must be completed, or ordered by the use of barrier operations, if they are not naturally ordered by the use of a common address, see *Ordering and completion of data and instruction cache instructions* on page D3-1614.

   Note

   With software management of coherency, race conditions can cause loss of data. A race condition occurs when different agents write simultaneously to bytes that are in the same location, and the invalidate, write, clean sequence of one agent overlaps with the equivalent sequence of another agent. A race condition also occurs if the first operation of either sequence is a clean, rather than an invalidate.

6. If the mismatched attributes for a location mean that multiple cacheable accesses to the location might be made with different shareability attributes, then coherency is guaranteed only if processing elements that accesses the location with a cacheable attribute performs a clean and invalidate of the location before and after accessing that location.

   Note

   The Note in rule 5 on page B2-98 about possible race conditions also applies to this rule.

In addition, if multiple agents attempt to use Load-Exclusive or Store-Exclusive instructions to access a location, and the accesses from the different agents have different memory attributes associated with the location, the exclusive monitor state becomes UNKNOWN.

ARM strongly recommends that software does not use mismatched attributes for aliases of the same location. An implementation might not optimize the performance of a system that uses mismatched aliases.

B2.10 Synchronization and semaphores

ARMv8 provides non-blocking synchronization of shared memory, using *synchronization primitives*. The information in this section about memory accesses by synchronization primitives applies to accesses to both Normal and Device memory.

Note

Use of the ARMv8 synchronization primitives scales for multiprocessing system designs.

Table B2-2 shows the synchronization primitives and the associated `CLREX` instruction.

Table B2-2 Synchronization primitives and associated instruction

Function	Instruction
Load-Exclusive	
Pair[a]	`LDXP, LDAXP`
Register[a]	`LDXR, LDAXR`
Halfword	`LDXRH, LDAXRH`
Byte	`LDXRB, LDAXRB`
Store-Exclusive	
Pair[a]	`STXP, STLXP`
Register[a]	`STXR, STLXR`
Halfword	`STXRH, STLXRH`
Byte	`STXRB, STLXRB`
Clear-Exclusive	`CLREX`

a. The instruction operates on a doubleword if accessing an X register, or on a word if accessing a W register.

The model for the use of a Load-Exclusive/Store-Exclusive instruction pair accessing a non-aborting memory address *x* is:

- The Load-Exclusive instruction reads a value from memory address *x*.
- The corresponding Store-Exclusive instruction succeeds in writing back to memory address *x* only if no other observer, process, or thread has performed a more recent store to address *x*. The Store-Exclusive instruction returns a status bit that indicates whether the memory write succeeded.

A Load-Exclusive instruction marks a small block of memory for exclusive access. The size of the marked block is IMPLEMENTATION DEFINED, see *Marking and the size of the marked memory block* on page B2-105. A Store-Exclusive instruction to any address in the marked block clears the marking.

Note

In this section, the term PE includes any observer that can generate a Load-Exclusive or a Store-Exclusive instruction.

B2.10.1 Exclusive access instructions and Non-shareable memory locations

For memory locations that do not have the *Shareable* attribute, the exclusive access instructions rely on a *local monitor* that marks any address from which the PE executes a Load-Exclusive instruction. Any non-aborted attempt by the same PE to use a Store-Exclusive instruction to modify any address is guaranteed to clear the marking.

A Load-Exclusive instruction performs a load from memory, and:

- The executing PE marks the physical memory address for exclusive access.
- The local monitor of the executing PE transitions to the Exclusive Access state.

A Store-Exclusive instruction performs a conditional store to memory that depends on the state of the local monitor:

If the local monitor is in the Exclusive Access state

- If the address of the Store-Exclusive instruction is the same as the address that has been marked in the monitor by an earlier Load-Exclusive instruction, then the store occurs. Otherwise, it is IMPLEMENTATION DEFINED whether the store occurs.
- A status value is returned to a register:
  - If the store took place the status value is 0.
  - Otherwise, the status value is 1.
- The local monitor of the executing PE transitions to the Open Access state.

If the local monitor is in the Open Access state

- No store takes place.
- A status value of 1 is returned to a register.
- The local monitor remains in the Open Access state.

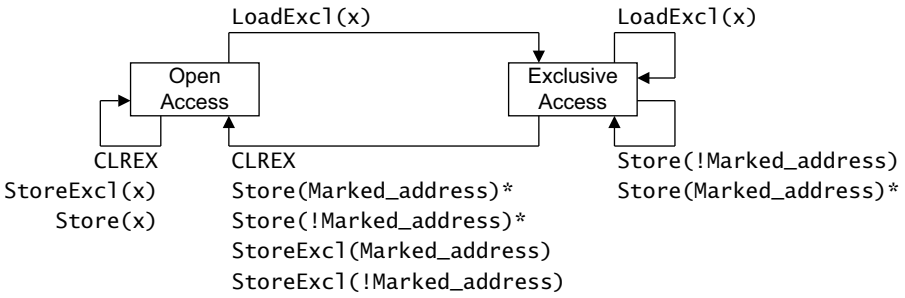
The Store-Exclusive instruction defines the register to which the status value is returned.

When a PE writes using any instruction other than a Store-Exclusive instruction:

- If the write is to a physical address that is not tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.
- If the write is to a physical address that is tagged by its local monitor it is IMPLEMENTATION DEFINED whether the write affects the state of the local monitor.

It is IMPLEMENTATION DEFINED whether a store to a marked physical address causes a mark in the local monitor to be cleared if that store is by an observer other than the one that caused the physical address to be marked.

Figure B2-4 shows the state machine for the local monitor and the effect of each of the operations shown in the figure.



Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: `LoadExcl` represents any Load-Exclusive instruction
`StoreExcl` represents any Store-Exclusive instruction
`Store` represents any other store instruction.

Any `LoadExcl` operation updates the marked address to the most significant bits of the address `x` used for the operation.

Figure B2-4 Local monitor state machine diagram

For more information about marking see *Marking and the size of the marked memory block* on page B2-105.

Note

For the local monitor state machine, as shown in Figure B2-4 on page B2-100:

- The IMPLEMENTATION DEFINED options for the local monitor are consistent with the local monitor being constructed so that it does not hold any physical address, but instead treats any access as matching the address of the previous Load-Exclusive instruction.
- A local monitor implementation can be unaware of Load-Exclusive and Store-Exclusive instructions from other PEs.
- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the local monitor.
- It is IMPLEMENTATION DEFINED whether the transition from Exclusive Access to Open Access state occurs when the `Store` or `StoreExcl` is from another observer.

Changes to the local monitor state resulting from speculative execution

The architecture permits a local monitor to transition to the Open Access state as a result of speculation, or from some other cause. This is in addition to the transitions to Open Access state caused by the architectural execution of an operation shown in Figure B2-4 on page B2-100.

An implementation must ensure that:

- The local monitor cannot be seen to transition to the Exclusive Access state except as a result of the architectural execution of one of the operations shown in Figure B2-4 on page B2-100.
- Any transition of the local monitor to the Open Access state not caused by the architectural execution of an operation shown in Figure B2-4 on page B2-100 must not indefinitely delay forward progress of execution.

B2.10.2 Exclusive access instructions and Shareable memory locations

For memory locations that have the *Shareable* attribute, exclusive access instructions rely on:

- A *local monitor* for each PE in the system, that marks any address from which the PE executes a Load-Exclusive. The local monitor operates as described in *Exclusive access instructions and Non-shareable memory locations* on page B2-100, except that for Shareable memory any Store-Exclusive is then subject to checking by the global monitor if it is described in that section as doing at least one of the following:
  - Updating memory.
  - Returning a status value of 0.

  The local monitor can ignore accesses from other PEs in the system.
- A *global monitor* that marks a physical address as exclusive access for a particular PE. This marking is used later to determine whether a Store-Exclusive to that address that has not been failed by the local monitor can occur. Any successful write to the marked block by any other observer in the shareability domain of the memory location is guaranteed to clear the marking. For each PE in the system, the global monitor:
  - Can hold one marked block.
  - Maintains a state machine for each marked block it can hold.

  Note

  For each PE, the architecture only requires global monitor support for a single marked address. Any situation that might benefit from the use of multiple marked addresses on a single PE is UNPREDICTABLE, see *Load-Exclusive and Store-Exclusive instruction usage restrictions* on page B2-105.

Note

The global monitor can either reside within the PE, or exist as a secondary monitor at the memory interfaces.The IMPLEMENTATION DEFINED aspects of the monitors mean that the global monitor and local monitor can be combined into a single unit, provided that the unit performs the global monitor and local monitor functions defined in this manual.

For Shareable locations of memory, in some implementations and for some memory types, the properties of the global monitor require functionality outside the PE. Some system implementations might not implement this functionality for all locations of memory. In particular, this can apply to:

- Any type of memory in the system implementation that does not support hardware cache coherency.
- Non-cacheable memory, or memory treated as Non-cacheable, in an implementation that does support hardware cache coherency.

In such a system, it is defined by the system:

- Whether the global monitor is implemented.
- If the global monitor is implemented, which address ranges or memory types it monitors.

Note

To support the use of the Load-Exclusive/Store-Exclusive mechanism when address translation is disabled, a system might define at least one location of memory, of at least the size of the translation granule, in the system memory map to support the global monitor for all ARM PEs within a common Inner Shareable domain. However, this is not an architectural requirement. Therefore, architecturally-compliant software that requires mutual exclusion must not rely on using the Load-Exclusive/Store-Exclusive mechanism, and must instead use a software algorithm such as Lamport's Bakery algorithm to achieve mutual exclusion.

Because implementations can choose which memory types are treated as Non-cacheable, the only memory types for which it is architecturally guaranteed that a global exclusive monitor is implemented are:

- Inner shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.
- Outer shareable, Inner Write-Back, Outer Write-Back Normal memory with Read allocation hints and Write allocation hints and not transient.

The set of memory types that support atomic instructions must include all of the memory types for which a global monitor is implemented.

If the global monitor is not implemented for an address range or memory type, then performing a Load-Exclusive/Store-Exclusive instruction to such a location has one or more of the following effects:

- The instruction generates an external abort.
- The instruction generates an IMPLEMENTATION DEFINED MMU fault. This is reported using the Fault Status code of ESR_ELx.DFSC = `110101`.
- The instruction is treated as a `NOP`.
- The Load-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN.
- The Store-Exclusive instruction is treated as if it were accessing a Non-shareable location, but the state of the local monitor becomes UNKNOWN. In this case, if the store exclusive instruction is a store exclusive pair of 64-bit quantities, then the two quantities being stored might not be stored atomically.
- The value held in the result register of the Store-Exclusive instruction becomes UNKNOWN.

In addition, for write transactions generated by non-PE observers that do not implement exclusive accesses or other atomic access mechanisms, the effect that writes have on the global and local monitors used by ARM PEs is IMPLEMENTATION DEFINED. The writes might not clear the global monitors of other PEs for:

- Some address ranges.
- Some memory types.

Operation of the global monitor

A Load-Exclusive instruction from Shareable memory performs a load from memory, and causes the physical address of the access to be marked as exclusive access for the requesting PE. This access also causes the exclusive access mark to be removed from any other physical address that has been marked by the requesting PE.

Note

The global monitor only supports a single outstanding exclusive access to Shareable memory per PE.

A Load-Exclusive instruction by one PE has no effect on the global monitor state for any other PE.

A Store-Exclusive instruction performs a conditional store to memory:

- The store is guaranteed to succeed only if the physical address accessed is marked as exclusive access for the requesting PE and both the local monitor and the global monitor state machines for the requesting PE are in the Exclusive Access state. In this case:
  - A status value of 0 is returned to a register to acknowledge the successful store.
  - The final state of the global monitor state machine for the requesting PE is IMPLEMENTATION DEFINED.
  - If the address accessed is marked for exclusive access in the global monitor state machine for any other PE then that state machine transitions to Open Access state.
- If no address is marked as exclusive access for the requesting PE, the store does not succeed:
  - A status value of 1 is returned to a register to indicate that the store failed.
  - The global monitor is not affected and remains in Open Access state for the requesting PE.
- If a different physical address is marked as exclusive access for the requesting PE, it is IMPLEMENTATION DEFINED whether the store succeeds or not:
  - If the store succeeds a status value of 0 is returned to a register, otherwise a value of 1 is returned.
  - If the global monitor state machine for the PE was in the Exclusive Access state before the Store-Exclusive instruction it is IMPLEMENTATION DEFINED whether that state machine transitions to the Open Access state.

The Store-Exclusive instruction defines the register to which the status value is returned.

In a shared memory system, the global monitor implements a separate state machine for each PE in the system. The state machine for accesses to Shareable memory by PE(n) can respond to all the Shareable memory accesses visible to it. This means it responds to:

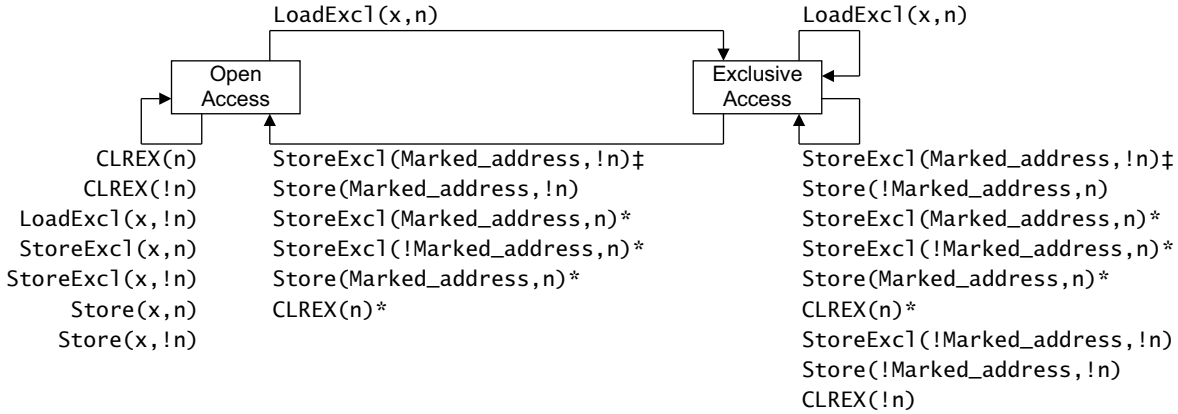
- Accesses generated by PE(n).
- Accesses generated by the other observers in the shareability domain of the memory location. These accesses are identified as (!n).

In a shared memory system, the global monitor implements a separate state machine for each observer that can generate a Load-Exclusive or a Store-Exclusive instruction in the system.

Clear global monitor event

Whenever the global monitor state for a PE changes from Exclusive access to Open access, an event is generated and held in the Event register for that PE. This register is used by the Wait for Event mechanism, see *Mechanisms for entering a low-power state* on page D1-1503.

Figure B2-5 shows the state machine for PE(n) in a global monitor.



‡StoreExcl(Marked_address,!n) clears the monitor only if the StoreExcl updates memory
Operations marked * are possible alternative IMPLEMENTATION DEFINED options.
In the diagram: LoadExcl represents any Load-Exclusive instruction
StoreExcl represents any Store-Exclusive instruction
Store represents any other store instruction.

Any LoadExcl operation updates the marked address to the most significant bits of the address x used for the operation.

Figure B2-5 Global monitor state machine diagram for PE(n) in a multiprocessor system

For more information about marking see *Marking and the size of the marked memory block* on page B2-105.

Note

For the global monitor state machine, as shown in Figure B2-5:

- The architecture does not require a load instruction by another PE, that is not a Load-Exclusive instruction, to have any effect on the global monitor.
- Whether a Store-Exclusive instruction successfully updates memory or not depends on whether the address accessed matches the marked Shareable memory address for the PE issuing the Store-Exclusive instruction, and whether the local and global monitors are in the exclusive state. For this reason, Figure B2-5 only shows how the operations by (!n) cause state transitions of the state machine for PE(n).
- A Load-Exclusive instruction can only update the marked Shareable memory address for the PE issuing the Load-Exclusive instruction.
- When the global monitor is in the Exclusive Access state, it is IMPLEMENTATION DEFINED whether a CLREX instruction causes the global monitor to transition from Exclusive Access to Open Access state.
- It is IMPLEMENTATION DEFINED:
  - Whether a modification to a Non-shareable memory location can cause a global monitor to transition from Exclusive Access to Open Access state.
  - Whether a Load-Exclusive instruction to a Non-shareable memory location can cause a global monitor to transition from Open Access to Exclusive Access state.

B2.10.3 Marking and the size of the marked memory block

When a Load-Exclusive instruction is executed, the resulting marked block ignores the least significant bits of the 64-bit memory address.

When a `LDXR` instruction is executed, a marked block of size 2^a is created by ignoring the least significant bits of the memory address. A marked address is any address within this marked block. For example, in an implementation where a is 4, a successful `LDXRB` of address `0x341B4` defines a marked block using bits[47:4] of the address. This means that the four words of memory from `0x341B0` to `0x341BF` are marked for exclusive access.

The size of the marked memory block is called the *Exclusives Reservation Granule*. The Exclusives Reservation Granule is IMPLEMENTATION DEFINED in the range 2 - 512 words:

- 3 words in an implementation where a is 4.
- 512 words in an implementation where a is 11.

In some implementations the CTR identifies the Exclusives Reservation Granule, see CTR_EL0. Otherwise, software must assume that the maximum Exclusives Reservation Granule, 512 words, is implemented.

B2.10.4 Context switch support

An exception return clears the local monitor. As a result, performing a `CLREX` instruction as part of a context switch is not required in most situations.

Note

Context switching is not an application level operation. However, this information is included here to complete the description of the exclusive operations.

B2.10.5 Load-Exclusive and Store-Exclusive instruction usage restrictions

The Load-Exclusive and Store-Exclusive instructions are intended to work together as a pair, for example a `LDXP`/`STXP` pair or a `LDXR`/`STXR` pair. To support different implementations of these functions, software must follow the notes and restrictions given here.

The following notes describe use of a Load-Exclusive/Store-Exclusive pair, `LoadExcl`/`StoreExcl`, to indicate the use of any of the Load-Exclusive/Store-Exclusive instruction pairs shown in Table B2-2 on page B2-99:

- The exclusives support a single outstanding exclusive access for each PE thread that is executed. The architecture makes use of this by not requiring an address or size check as part of the `IsExclusiveLocal()` function. If the target virtual address of a `StoreExcl` is different from the virtual address of the preceding `LoadExcl` instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, a `LoadExcl`/`StoreExcl` pair can only be relied upon to eventually succeed if the `LoadExcl` and the `StoreExcl` are executed with the same virtual address.
- If two `StoreExcl` instructions are executed without an intervening `LoadExcl` instruction the second `StoreExcl` instruction returns a status value of 1. This means that:
  — ARM recommends that, in a given thread of execution, every `StoreExcl` instruction has a preceding `LoadExcl` instruction associated with it.

  It is not necessary for every `LoadExcl` instruction to have a subsequent `StoreExcl` instruction.
- An implementation of the Load-Exclusive and Store-Exclusive instructions can require that, in any thread of execution, the transaction size of a Store-Exclusive instruction is the same as the transaction size of the preceding Load-Exclusive instruction executed in that thread. If the transaction size of a Store-Exclusive instruction is different from the preceding Load-Exclusive instruction in the same thread of execution, behavior can be UNPREDICTABLE. As a result, software can rely on an `LoadExcl`/`StoreExcl` pair to eventually succeed only if they have the same size.

- An implementation might clear an exclusive monitor between the `LoadExcl` instruction and the `StoreExcl`, instruction without any application-related cause. For example, this might happen because of cache evictions. Software must, in any single thread of execution, avoid having any explicit memory accesses or cache maintenance instructions between the `LoadExcl` instruction and the associated `StoreExcl` instruction.
- Implementations can benefit from keeping the `LoadExcl` and `StoreExcl` operations close together in a single thread of execution. This minimizes the likelihood of the exclusive monitor state being cleared between the `LoadExcl` instruction and the `StoreExcl` instruction. Therefore, for best performance, ARM strongly recommends a limit of 128 bytes between `LoadExcl` and `StoreExcl` instructions in a single thread of execution.
- The architecture sets an upper limit of 2048 bytes on the exclusive reservation granule that can be marked as exclusive. For performance reasons, ARM recommends that objects that are accessed by exclusive accesses are separated by the size of the exclusive reservations granule. This is a performance guideline rather than a functional requirement.
- After taking a Data Abort exception, the state of the exclusive monitors is UNKNOWN.
- If the memory attributes for the memory being accessed by a `LoadExcl`/`StoreExcl` pair differ between the `LoadExcl` instruction and the `StoreExcl` instruction, behavior is UNPREDICTABLE. This can occur either:
  - Because the translation has changed between the Load-Exclusive and the Store-Exclusive.
  - As a result of using different virtual addresses, with different attributes, that point to the same physical address. This case is covered by another bullet point in this list.
- The effect of a data or unified cache invalidate, clean, or clean and invalidate instruction on a local or global exclusive monitor that is in the Exclusive Access state is UNPREDICTABLE. The instruction might clear the monitor, or it might leave it in the Exclusive Access state. For address-based maintenance instructions, this also applies to the monitors of other PEs in the same shareability domain as the PE executing the cache maintenance instruction, as determined by the shareability domain of the address being maintained.

  Note

  ARM strongly recommends that implementations ensure that the use of such maintenance instructions by a PE in the Non-secure state cannot cause a denial of service on a PE in the Secure state.

Note

In the event of repeatedly-contending Load-Exclusive/Store-Exclusive instruction sequences from multiple PEs, an implementation must ensure that forward progress is made by at least one PE.

B2.10.6 Use of WFE and SEV instructions by spin-locks

ARMv8 provides Wait For Event, Send Event, and Send Event Local instructions, `WFE`, `SEV`, and `SEVL`, that can assist with reducing power consumption and bus contention caused by PEs repeatedly attempting to obtain a spin-lock. These instructions can be used at the application level, but a complete understanding of what they do depends on a system level understanding of exceptions. They are described in *Wait for Event mechanism and Send event* on page D1-1503. However, in ARMv8, when the global monitor for a PE changes from Exclusive Access state to Open Access state, an event is generated.

Note

This is equivalent to issuing an `SEV` instruction on the PE for which the monitor state has changed. It removes the need for spinlock code to include an `SEV` instruction after clearing a spinlock.

Part C

The AArch64 Instruction Set

Chapter C1
The A64 Instruction Set

This chapter describes the A64 instruction set. It contains the following sections:

C1.1 Introduction

The instruction set supported in the AArch64 Execution state is known as A64.

All A64 instructions have a width of 32 bits. The A64 encoding structure breaks down into the following functional groups:

- A miscellaneous group of branch instructions, exception generating instructions, and system instructions.
- Data processing instructions associated with general-purpose registers. These instructions are supported by two *functional groups*, depending on whether the operands:
  - Are all held in registers.
  - Include an operand with a constant immediate value.
- Load and store instructions associated with the general-purpose register file and the SIMD and floating-point register file.
- SIMD and scalar floating-point data processing instructions that operate on the SIMD and floating-point registers.

The encoding hierarchy within a functional group breaks down as follows:

- A functional group consists of a set of related instruction classes. *A64 instruction index by encoding* on page C4-174 provides an overview of the instruction encodings in the form of a list of instruction classes within their functional groups.
- An instruction class consists of a set of related instruction forms. Instruction forms are documented in one of two alphabetic lists:
  - The load, store, and data processing instructions associated with the general-purpose registers, together with those in the other instruction classes. See Chapter C6 *A64 Base Instruction Descriptions*.
  - The load, store, and data processing instructions associated with the SIMD and floating-point support. See Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.
- An instruction form might support a single instruction syntax. Where an instruction supports more than one syntax, each syntax is an *instruction variant*. Instruction variants can occur because of differences in:
  - The size or format of the operands.
  - The register file used for the operands.
  - The addressing mode used for load/load/store memory operands.

  Instruction variants might also arise as the result of other factors.

  Instruction variants are described in the instruction description for the individual instructions.

A64 instructions have a regular bit encoding structure:

- 5-bit register operand fields at fixed positions within the instruction. For general-purpose register operands, the values 0-30 select one of 31 registers. The value 31 is used as a special case that can:
  - Indicate use of the current stack pointer, when identifying a load/store base register or in a limited set of data processing instructions. See *The stack pointer registers* on page D1-1408.
  - Indicate the value zero when used as a source register operand.
  - Indicate discarding the result when used as a destination register operand.

  For SIMD and floating-point register access, the value used selects one of 32 registers.
- Immediate bits that provide constant data processing values or address offsets are placed in contiguous bit fields. Some computed values in instruction variants use one or more immediate bit fields together with the secondary encoding bit fields.

All encodings that are not fully defined are described as unallocated. An attempt to execute an unallocated instruction results in an Undefined Instruction exception, unless otherwise defined in the Exception model.

C1.2 Structure of the A64 assembler language

The letter *W* denotes a general-purpose register holding a 32-bit word, and *X* denotes a general-purpose register holding a 64-bit doubleword.

An A64 assembler recognizes both upper-case and lower-case variants of the instruction mnemonics and register names, but not mixed case variants. An A64 disassembler can output either upper-case or lower-case mnemonics and register names. Program and data labels are case-sensitive.

The A64 assembly language does not require the # character to introduce constant immediate operands, but an assembler must allow immediate values introduced with or without the # character. ARM recommends that an A64 disassembler outputs a # before an immediate operand.

In Example C1-1 on page C1-112 the sequence // is used as a comment leader and A64 assemblers are encouraged to accept this syntax.

C1.2.1 Common syntax terms

The following syntax terms are used frequently throughout the A64 instruction set description.

`UPPER` Text in upper-case letters is fixed. Text in lower-case letters is variable. This means that register name `Xn` indicates that the `X` is required, followed by a variable register number, for example `X29`.

`< >` Any text enclosed by angle braces, < >, is a value that the user supplies. Subsequent text might supply additional information.

`{ }` Any item enclosed by curly brackets, { }, is optional. A description of the item and how its presence or absence affects the instruction is normally supplied by subsequent text. In some cases curly braces are actual symbols in the syntax, for example when they surround a register list. These cases are called out in the surrounding text.

`[ ]` Any items enclosed by square brackets, [ ], constitute a list of alternative characters. A single one of the characters can be used in that position and the subsequent text describes the meaning of the alternatives. In some case the square brackets are part of the syntax itself, such as addressing modes or vector elements. These cases are called out in the surrounding text.

`a|b` Alternative words are separated by a vertical bar, |, and can be surrounded by parentheses to delimit them. For example, `U(ADD|SUB)W` represents `UADDW` or `USUBW`.

`±` This indicates an optional + or - sign. If neither is used then + is assumed.

`uimm`*n* An *n*-bit unsigned, positive, immediate value.

`simm`*n* An *n*-bit two's complement, signed immediate value, where *n* includes the sign bit.

`SP` See *Register names* on page C1-112.

`Wn` See *Register names* on page C1-112.

`WSP` See *Register names* on page C1-112.

`WZR` See *Register names* on page C1-112.

`Xn` See *Register names* on page C1-112.

`XZR` See *Register names* on page C1-112

C1.2.2 Instruction Mnemonics

The A64 assembly language overloads instruction mnemonics and distinguishes between the different forms of an instruction based on the operand types. For example, the following `ADD` instructions all have different opcodes. However, the programmer must only remember one mnemonic, as the assembler automatically chooses the correct opcode based on the operands. The disassembler follows the same procedure in reverse.

Example C1-1 ADD instructions with different opcodes

```
ADD W0, W1, W2              // add 32-bit register
ADD X0, X1, X2              // add 64-bit register
ADD X0, X1, W2, SXTW        // add 64-bit extended register
ADD X0, X1, #42             // add 64-bit immediate
```

C1.2.3 Condition Code

The A64 ISA has some instructions that set condition flags or test condition codes or both. For information about instructions that set the condition flags or use the condition mnemonics, see *Condition flags and related instructions* on page C6-386.

Table C1-1 shows the available condition codes.

Table C1-1 Condition codes

cond	Mnemonic	Meaning (integer)	Meaning (floating-point)[a]	Condition flags
0000	EQ	Equal	Equal	Z == 1
0001	NE	Not equal	Not equal or unordered	Z == 0
0010	CS or HS	Carry set	Greater than, equal, or unordered	C == 1
0011	CC or LO	Carry clear	Less than	C == 0
0100	MI	Minus, negative	Less than	N == 1
0101	PL	Plus, positive or zero	Greater than, equal, or unordered	N == 0
0110	VS	Overflow	Unordered	V == 1
0111	VC	No overflow	Ordered	V == 0
1000	HI	Unsigned higher	Greater than, or unordered	C ==1 && Z == 0
1001	LS	Unsigned lower or same	Less than or equal	!(C ==1 && Z ==0)
1010	GE	Signed greater than or equal	Greater than or equal	N == V
1011	LT	Signed less than	Less than, or unordered	N! = V
1100	GT	Signed greater than	Greater than	Z == 0 && N == V
1101	LE	Signed less than or equal	Less than, equal, or unordered	!(Z == 0 && N == V)
1110	AL	Always	Always	Any
1111	NV[b]	Always	Always	Any

a. Unordered means at least one NaN operand.

b. The condition code NV exists only to provide a valid disassembly of the 0b1111 encoding, otherwise its behavior is identical to AL.

C1.2.4 Register names

This section describes the AArch64 registers. It contains the following subsections:

- *General-purpose register file and the stack pointer* on page C1-113.
- *SIMD and floating-point register file* on page C1-113.
- *SIMD and floating-point scalar register names* on page C1-114.
- *SIMD vector register names* on page C1-114.

- *SIMD vector element names* on page C1-114.

General-purpose register file and the stack pointer

The 31 general-purpose registers in the general-purpose register file are named R0-R30 and encoded in the instruction register fields with values 0-30. A general-purpose register field that encodes the value 31 represents represents either the current stack pointer or the zero register, depending on the instruction and the operand position.

When the registers are used in a specific instruction variant, they must be qualified to indicate the operand data size, 32 bits or 64 bits, and the data size of the instruction.

When the data size is 32 bits, the lower 32 bits of the register are used and the upper 32 bits are ignored on a read and cleared to zero on a write.

Table C1-2 shows the qualified names for registers, where *n* is a register number 0-30.

Table C1-2 General-purpose register names

Name	Size	Encoding	Description
Wn	32 bits	0-30	General-purpose register 0-30
Xn	64 bits	0-30	General-purpose register 0-30
WZR	32 bits	31	Zero register
XZR	64 bits	31	Zero register
WSP	32 bits	31	Current stack pointer
SP	64 bits	31	Current stack pointer

The following list provides further details relating to Table C1-2.

- The names Xn and Wn both refer to the same general-purpose register, Rn.
- There is no register named W31 or X31.
- The name SP represents the stack pointer for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as a read or write of the current stack pointer. When instructions do not interpret this operand encoding as the stack pointer, use of the name SP is an error.
- The name WSP represents the current stack pointer in a 32-bit context.
- The name XZR represents the zero register for 64-bit operands where an encoding of the value 31 in the corresponding register field is interpreted as returning zero when read or discarding the result when written. When instructions do not interpret this operand encoding as the zero register, use of the name XZR is an error.
- The name WZR represents the zero register in a 32-bit context.
- The architecture does not define a special name for general-purpose register R30 that reflects its special role as the link register on procedure calls. An A64 assembler must always use W30 and X30. Additional software names might be defined as part of the Procedure Call Standard, see *Procedure Call Standard for the ARM 64-bit Architecture*.

SIMD and floating-point register file

The 32 registers in the SIMD and floating-point register file, V0-V31, hold floating-point operands for the scalar floating-point instructions, and both scalar and vector operands for the SIMD instructions. When they are used in a specific instruction form, the names must be further qualified to indicate the data shape, that is the data element size and the number of elements or lanes within the register. A similar requirement is placed on the general-purpose registers. See *General-purpose register file and the stack pointer*.

Note

The data type is described by the instruction mnemonics that operate on the data. The data type is not described by the register name. The data type is the interpretation of bits within each register or vector element, whether these are integers, floating-point values, polynomials or cryptographic hashes.

SIMD and floating-point scalar register names

SIMD and floating-point instructions that operate on scalar data only access the lower bits of a SIMD and floating-point register. The unused high bits are ignored on a read and cleared to 0 on a write.

Table C1-3 shows the qualified names for accessing scalar SIMD and floating-point registers. The letter *n* denotes a register number between 0 and 31.

Table C1-3 SIMD and floating-point scalar register names

Size	Name
8 bits	`Bn`
16 bits	`Hn`
32 bits	`Sn`
64 bits	`Dn`
128 bits	`Qn`

SIMD vector register names

If a register holds multiple data elements on which arithmetic is performed in a parallel, SIMD, manner, then a qualifier describes the vector shape. The vector shape is the element size and the number of elements or lanes. If the element size in bits multiplied by the number of lanes does not equal 128, then the upper 64 bits of the register are ignored on a read and cleared to zero on a write.

Table C1-4 shows the SIMD vector register names. The letter *n* denotes a register number between 0 and 31.

Table C1-4 SIMD vector register names

Shape	Name
8 bits × 8 lanes	`Vn.8B`
8 bits × 16 lanes	`Vn.16B`
16 bits × 4 lanes	`Vn.4H`
16 bits × 8 lanes	`Vn.8H`
32 bits × 2 lanes	`Vn.2S`
32 bits × 4 lanes	`Vn.4S`
64 bits × 1 lane	`Vn.1D`
64 bits × 2 lanes	`Vn.2D`

SIMD vector element names

Appending a constant, zero-based element index to the register name inside square brackets indicates that a single element from a SIMD and floating-point register is used as a scalar operand. The number of lanes is not represented, as it is not encoded in the instruction and can only be inferred from the index value.

Table C1-5 shows the vector register names and the element index. The letter *i* denotes the element index.

Table C1-5 Vector register names with element index

Size	Name
8 bits	`Vn.B[i]`
16 bits	`Vn.H[i]`
32 bits	`Vn.S[i]`
64 bits	`Vn.D[i]`

An assembler must accept a fully qualified SIMD register name, if the number of lanes is greater than the index value. See *SIMD vector register names* on page C1-114. For example, an assembler must accept all of the following forms as the name for the 32-bit element in bits [63:32] of the SIMD and floating-point register V9:

```
V9.S[1]     //standard disassembly
V9.2S[1]    //optional number of lanes
V9.4S[1]    //optional number of lanes
```

Note

The SIMD and floating-point register element name `Vn.S[0]` is not equivalent to the scalar SIMD and floating-point register name `Sn`. Although they represent the same bits in the register, they select different instruction encoding forms, either the vector element or the scalar form.

SIMD vector register list

Where an instruction operates on multiple SIMD and floating-point registers, for example vector Load/Store structure and table lookup operations, the registers are specified as a list enclosed by curly braces. This list consists of either a sequence of registers separated by commas, or a register range separated by a hyphen. The registers must be numbered in increasing order, modulo 32, in increments of one. The hyphenated form is preferred for disassembly if there are more than two registers in the list and the register number are increasing. The following examples are equivalent representations of a set of four registers `V4` to `V7`, each holding four lanes of 32-bit elements:

```
{ V4.4S - V7.4S }              //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S } //alternative representation
```

SIMD vector element list

Registers in a list can also have a vector element form. For example, the `LD4` instruction can load one element into each of four registers, and in this case the index is appended to the list as follows:

```
{ V4.S - V7.S }[3]                //standard disassembly
{ V4.4S, V5.4S, V6.4S, V7.4S }[3] //alternative with optional number of lanes
```

C1.3 Address generation

The A64 instruction set supports 64-bit addresses. The valid address range is determined by the following factors:

- The size of the implemented virtual address space.
- Memory Management Unit (MMU) configuration settings.

The top 8 bits of the 64-bit address can be used as a tag, see *Address tagging in AArch64 state* on page D4-1634. For more information on memory management and address translation, see Chapter D4 *The AArch64 Virtual Memory System Architecture*.

C1.3.1 Register indexed addressing

The A64 instruction set allows a 64-bit index register to be added to the 64-bit base register, with optional scaling of the index by the access size. Additionally it allows for sign-extension or zero-extension of a 32-bit value within an index register, followed by optional scaling.

C1.3.2 PC-relative addressing

The A64 instruction set has support for position-independent code and data addressing:

- PC-relative literal loads have an offset range of ± 1MB.
- Process state flag and compare based conditional branches have a range of ± 1MB. Test bit conditional branches have a restricted range of ± 32KB.
- Unconditional branches, including branch and link, have a range of ± 128MB.

PC-relative Load/Store operations, and address generation with a range of ± 4GB can be performed using two instructions.

C1.3.3 Load/Store addressing modes

Load/Store addressing modes in the A64 instruction set require a 64-bit base address from a general-purpose register X0-X30 or the current stack pointer, `SP`, with an optional immediate or register offset. Table C1-6 shows the assembler syntax for the complete set of Load/Store addressing modes.

Table C1-6 A64 Load/Store addressing modes

Addressing Mode	Offset		
	Immediate	Register	Extended Register
Base register only (no offset)	`[base{, #0}]`	-	-
Base plus offset	`[base{, #imm}]`	`[base, Xm{, LSL #imm}]`	`[base, Wm, (S|U)XTW {#imm}]`
Pre-indexed	`[base, #imm]!`	-	-
Post-indexed	`[base], #imm`	`[base], Xm`[a]	-
Literal (PC-relative)	`label`	-	-

a. The post-indexed by register offset mode can be used with the SIMD Load/Store structure instructions described in *Load/Store Vector* on page C3-139. Otherwise the post-indexed by register offset mode is not available.

Some types of Load/Store instruction support only a subset of the Load/Store addressing modes listed in Table C1-6 on page C1-116. Details of the supported modes are as follows:

- Base plus offset addressing means that the address is the value in the 64-bit base register plus an offset.
- Pre-indexed addressing means that the address is the sum of the value in the 64-bit base register and an offset, and the address is then written back to the base register.
- Post-indexed addressing means that the address is the value in the 64-bit base register, and the sum of the address and the offset is then written back to the base register.
- Literal addressing means that the address is the value of the 64-bit program counter for this instruction plus a 19-bit signed word offset. This means that it is a 4 byte aligned address within ±1MB of the address of this instruction with no offset. Literal addressing can only be used for loads of at least 32 bits and for prefetch instructions. The PC cannot be referenced using any other addressing modes. The syntax for labels is specific to individual toolchains.
- An immediate offset can be unsigned or signed, and scaled or unscaled, depending on the type of Load/Store instruction. When the immediate offset is scaled it is encoded as a multiple of the transfer size, although the assembly language always uses a byte offset, and the assembler or disassembler performs the necessary conversion. The usable byte offsets therefore depend on the type of Load/Store instruction and the transfer size.

  Table C1-7 shows the offset and the type of Load/Store instruction.

Table C1-7 Immediate offsets and the type of Load/Store instruction

Offset bits	Sign	Scaling	Write-Back	Load/Store type
0	-	-	-	Exclusive/acquire/release
7	Signed	Scaled	Optional	Register pair
9	Signed	Unscaled	Optional	Single register
12	Unsigned	Scaled	No	Single register

- A register offset means that the offset is the 64 bits from a general-purpose register, Xm, optionally scaled by the transfer size, in bytes, if `LSL #imm` is present and where `imm` must be equal to $\log_2$(transfer_size).
- An extended register offset means that offset is the bottom 32 bits from a general-purpose register Wm, sign-extended or zero-extended to 64 bits, and then scaled by the transfer size if so indicated by `#imm`, where imm must be equal to $\log_2$(transfer_size). An assembler must accept Wm or Xm as an extended register offset, but Wm is preferred for disassembly.
- Generating an address lower than the value in the base register requires a negative signed immediate offset or a register offset holding a negative value.
- When stack alignment checking is enabled by system software and the base register is the SP, the current stack pointer must be initially quadword aligned, that is aligned to 16 bytes. Misalignment generates a Stack Alignment fault. The offset does not have to be a multiple of 16 bytes unless the specific Load/Store instruction requires this. SP can not be used as a register offset.

Address calculation

General-purpose arithmetic instructions can calculate the result of most addressing modes and write the address to a general-purpose register or, in most cases, to the current stack pointer.

Table C1-8 shows the arithmetic instructions that can compute addressing modes.

Table C1-8 Arithmetic instructions to compute addressing modes

Addressing Form	Offset		
	Immediate	Register	Extended Register
Base register (no offset)	`MOV Xd|SP, base`	-	-

Base plus offset	`ADD Xd|SP, base, #imm`
	or
	`SUB Xd|SP, base, #imm`
		`ADD <Xd|SP>, base, Xm{,LSL#imm}`	`ADD <Xd|SP>, base, Wm,(S|U)XT(W|H|B|) {#imm}`

Pre-indexed	-	-	-
Post-indexed	-	-	-
Literal (PC-relative)	`ADR Xd, label`	-	-

Note

- To calculate a base plus immediate offset the `ADD` instructions defined in *Arithmetic (immediate)* on page C3-142 accept an unsigned 12-bit immediate offset, with an optional left shift by 12. This means that a single `ADD` instruction cannot support the full range of byte offsets available to a single register Load/Store with a scaled 12-bit immediate offset. For example, a quadword `LDR` effectively has a 16-bit byte offset. To calculate an address with a byte offset that requires more than 12 bits it is necessary to use two `ADD` instructions. The following example shows this:

  ```
  ADD  Xd, base, #(imm & 0xFFF)
  ADD  Xd, Xd, #(imm>>12), LSL #12
  ```

- To calculate a base plus extended register offset, the `ADD` instructions defined in *Arithmetic (extended register)* on page C3-147 provide a superset of the addressing mode that also supports sign-extension or zero-extension of a byte or halfword value with any shift amount between 0 and 4, for example:

  ```
  ADD   Xd, base, Wm, SXTW #3     // Xd = base + (SignExtend(Wm) LSL 3)
  ADD   Xd, base, Wm, UXTH #4     // Xd = base + (ZeroExtend(Wm<15:0>) LSL 4)
  ```

- If the same extended register offset is used by more than one Load/Store instruction, then, depending on the implementation, it might be more efficient to calculate the extended and scaled intermediate result just once, and then re-use it as a simple register offset. The extend and scale calculation can be performed using the `SBFIZ` and `UBFIZ` bitfield instructions defined in *Bitfield move* on page C3-144, for example:

  ```
  SBFIZ Xd, Xm, #3, #32     //Xd = “Wm, SXTW #3”
  UBFIZ Xd, Xm, #4, #16     //Xd = “Wm, UXTH #4”
  ```

C1.4 Instruction aliases

Some instructions have an associated *architecture alias* that is used for disassembly of the encoding when the associated conditions are met. Architecture alias instructions are included in the alphabetic lists of instruction types and clearly presented as an alias form in descriptions for the individual instructions.

Chapter C2
About the A64 Instruction Descriptions

This chapter describes the *instruction descriptions* that the following chapters include:

- Chapter C6 *A64 Base Instruction Descriptions*.
- Chapter C7 *A64 Advanced SIMD and Floating-point Instruction Descriptions*.

It contains the following section:

C2.1 Format of the A64 instruction descriptions

Each instruction description in Chapter C6 and Chapter C7 has the following content:

- *A title*.
- *An introduction to the instruction section*.
- *An instruction encoding or instruction encodings section*.
- *Alias conditions* on page C2-123.
- *Assembler symbols* on page C2-123.
- *Pseudocode describing how the instruction operates* on page C2-124.
- *Notes, if applicable* on page C2-124.

The following sections describe each of these in more detail.

C2.1.1 A title

The title of an instruction description is the base mnemonic for the instruction.

If the same base mnemonic is the title of two or more instruction descriptions, the mnemonic is followed by a short description of the *instruction form* in parentheses. This is most often used to distinguish between forms of an instruction where for one form one of the operands is an immediate value, and for another form it is a register.

For example, in Chapter C6, there are the following:

- *ADD (extended register)* on page C6-390.
- *ADD (immediate)* on page C6-392.
- *ADD (shifted register)* on page C6-394.

C2.1.2 An introduction to the instruction section

This briefly describes the main features of the instruction. The description in the introduction section is not necessarily a complete description and it is not definitive. If there is any conflict between it and the more detailed information that follows, the latter takes priority.

C2.1.3 An instruction encoding or instruction encodings section

This describes the instruction encoding, or if an instruction has more than one encoding, describes all of the encodings. Each encoding has a subheading. The subheadings might be, for example:

- Post-index.
- Pre-index.
- Unsigned offset.

For each encoding, there is:

- An encoding diagram that numbers the bits from 31 to 0. When the instruction ordering is little endian, the diagram for an instruction at address A shows the bytes at addresses A+3, A+2, A+1, and A, from left to right.

  There might be variants of an encoding, if the assembler syntax prototype differs depending on the value in one or more of the encoding fields. In this case, each variant has a subheading that describes the variant and lists the distinguishing field values in parentheses. For example in Chapter C6, there are the following variant subheadings for the `ADC` instruction:

  — 32-bit variant (sf = 0).
  — 64-bit variant (sf = 1).

  The assembler syntax prototype for each variant includes the mnemonic and all other parts that form a complete assembler source code instruction that assembles to the instruction encoding. Unless otherwise stated, the syntax prototype is also the preferred syntax for a disassembler to disassemble the variant to. Disassemblers are permitted to use simpler syntax, when it is beneficial given the operand combination, to produce more readable disassembled code. However, the resulting output must match the assembler prototype, and must re-assemble to the same encoding.

- Encoding-specific pseudocode. This is pseudocode that translates the encoding-specific instruction fields into inputs to the encoding-independent pseudocode in the *Operation* subsection, and that picks out any special cases in the encoding. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H *ARM Pseudocode Definition*.

C2.1.4 Alias conditions

This is an optional subsection of an instruction description. If included, it describes the set of conditions when an alternative assembler mnemonic and syntax is preferred for disassembly by a disassembler. It includes a link to the alias instruction description that defines the alternative syntax. The alias syntax and the encoding syntax can be used interchangeably in the assembler source code.

C2.1.5 Assembler symbols

The following conventions are used in the assembler syntax prototypes:

`< >` Any item bracketed by < and > identifies a name or a value that is supplied by the user. A longer description of the name or value is normally supplied by subsequent text. The subsequent text usually specifies the field or fields that the name or text is encoded in.

If a binary encoding of an integer constant or register number is substituted into the instruction encoding, this is not explained explicitly. For example, if the assembler syntax for an instruction contains an item, `<Rn>`, and the encoding diagram contains a 4-bit field, Rn, the number of the register specified in the assembler syntax is encoded in binary in the Rn field.

If the correspondence between the bracketed item and the instruction encoding is more complex than a binary encoding of an integer or a register number, the subsequent text indicates how it is encoded, often by including a list that shows the mapping from item to associated field value.

`{ }` Any item bracketed by { and } is optional. A description of the item and how its presence or absence is encoded in the instruction is normally supplied by subsequent text.

`#` This normally precedes a numeric constant. All uses of # are optional in assembler source code. ARM recommends that disassemblers output the # where it is shown.

`+/-` This indicates an optional + or - sign. If neither is coded, + is assumed.

Single spaces are used for clarity, to separate items. When a space is obligatory in the assembler syntax, two or more consecutive spaces are used.

All other characters must be encoded precisely as they appear in the assembler syntax. Apart from { and }, the special characters described above do not appear in the basic forms of assembler instructions documented in this manual. In a few places, the { and } characters are required characters in the assembly syntax, for example when surrounding a register list. When this happens, they are separated from other syntax items by one or more spaces.

The AArch64 register names, encodings and semantics are described in *Register names* on page C1-112. However, in the assembler syntax prototypes, the following symbol conventions are used:

<Xn> The 64-bit name of a general-purpose register (X0-X30) or zero register (XZR).

<Wn> The 32-bit name of a general-purpose register (W0-W30) or zero register (WZR).

<Xn|SP> The 64-bit name of a general-purpose register (X0-X30) or current stack pointer (SP).

<Wn|WSP> The 32-bit name of a general-purpose register (W0-W30) or current stack pointer (WSP).

<Bn>, <Hn>, <Sn>, <Dn>, <Qn>

The 8, 16, 32, 64 or 128-bit name of a SIMD and floating-point register in a scalar context as described in section C1.2.4

<Vn> The name of a SIMD and floating-point register name in a vector context as described in *Register names* on page C1-112.

The explanation of a symbol that specifies a register sometimes extends or restricts the permitted range of registers, or documents other differences from the default rules for such fields.

C2.1.6 Pseudocode describing how the instruction operates

This contains encoding-independent pseudocode that describes the main operation of the instruction. For a detailed description of the pseudocode used and of the relationship between the encoding diagram, the encoding-specific pseudocode and the encoding-independent pseudocode, see Appendix H *ARM Pseudocode Definition*.

C2.1.7 Notes, if applicable

Where appropriate, other notes about the instruction appear under additional subheadings.

Chapter C3
A64 Instruction Set Overview

This chapter provides an overview of the A64 instruction set. It contains the following sections:

- *Branches, Exception generating, and System instructions* on page C3-126.
- *Loads and stores* on page C3-131.
- *Data processing - immediate* on page C3-142.
- *Data processing - register* on page C3-147.
- *Data processing - SIMD and floating-point* on page C3-154.

For a structured breakdown of instruction groups by encoding, see Chapter C4 *A64 Instruction Set Encoding*.

C3.1 Branches, Exception generating, and System instructions

This section describes the branch, exception generating, and system instructions. It contains the following subsections:

- *Conditional branch*.
- *Unconditional branch (immediate)*.
- *Unconditional branch (register)* on page C3-127.
- *Exception generation and return* on page C3-127.
- *System register instructions* on page C3-128.
- *System instructions* on page C3-128.
- *Hint instructions* on page C3-129.
- *Barriers and CLREX instructions* on page C3-129.

For information about the encoding structure of the instructions in this instruction group, see *Branches, exception generating and system instructions* on page C4-175.

Note

Software must:

- Use only `BLR` or `BL` to perform a nested subroutine call when that subroutine is expected to return to the immediately following instruction, that is, the instruction with the address of the `BLR` or `BL` instruction incremented by four.
- Use only `RET` to perform a subroutine return, when that subroutine is expected to have been entered by a `BL` or `BLR` instruction.
- Use only `B`, `BR`, or the instructions listed in Table C3-1 to perform a control transfer that is not a subroutine call or subroutine return described in this *Note*.

C3.1.1 Conditional branch

Conditional branches change the flow of execution depending on the current state of the condition flags or the value in a general-purpose register. See Table C1-1 on page C1-112 for a list of the condition codes that can be used for `cond`.

Table C3-1 shows the Conditional branch instructions.

Table C3-1 Conditional branch instructions

Mnemonic	Instruction	Branch offset range from the PC	See
`B.cond`	Branch conditionally	±1MB	*B.cond* on page C6-415
`CBNZ`	Compare and branch if nonzero	±1MB	*CBNZ* on page C6-429
`CBZ`	Compare and branch if zero	±1MB	*CBZ* on page C6-430
`TBNZ`	Test bit and branch if nonzero	±32KB	*TBNZ* on page C6-749
`TBZ`	Test bit and branch if zero	±32KB	*TBZ* on page C6-750

C3.1.2 Unconditional branch (immediate)

Unconditional branch (immediate) instructions change the flow of execution unconditionally by adding an immediate offset with a range of ±128MB to the value of the program counter that fetched the instruction. The `BL` instruction also writes the address of the sequentially following instruction to general-purpose register, X30.

Table C3-2 shows the Unconditional branch instructions with an immediate branch offset.

Table C3-2 Unconditional branch instructions (immediate)

Mnemonic	Instruction	Immediate branch offset range from the PC	See
B	Branch unconditionally	±128MB	*B* on page C6-416
BL	Branch with link	±128MB	*BL* on page C6-425

C3.1.3 Unconditional branch (register)

Unconditional branch (register) instructions change the flow of execution unconditionally by setting the program counter to the value in a general-purpose register. The BLR instruction also writes the address of the sequentially following instruction to general-purpose register X30. The RET instruction behaves identically to BR, but provides an additional hint to the PE that this is a return from a subroutine.Table C3-3 shows Unconditional branch instructions that jump directly to an address held in a general-purpose register.

Table C3-3 Unconditional branch instructions (register)

Mnemonic	Instruction	See
BLR	Branch with link to register	*BLR* on page C6-426
BR	Branch to register	*BR* on page C6-427
RET	Return from subroutine	*RET* on page C6-637

C3.1.4 Exception generation and return

This section describes the following exceptions:

- *Exception generating*.
- *Exception return* on page C3-128.
- *Debug state* on page C3-128.

Exception generating

Table C3-4 shows the Exception generating instructions.

Table C3-4 Exception generating instructions

Mnemonic	Instruction	See
BRK	Software breakpoint instruction	*BRK* on page C6-428
HLT	Halting software breakpoint instruction	*HLT* on page C6-479
HVC	Generate exception targeting Exception level 2	*HVC* on page C6-480
SMC	Generate exception targeting Exception level 3	*SMC* on page C6-658
SVC	Generate exception targeting Exception level 1	*SVC* on page C6-743

Exception return

Table C3-5 shows the Exception return instructions.

Table C3-5 Exception return instructions

Mnemonic	Instruction	See
ERET	Exception return using current ELR and SPSR	*ERET* on page C6-474

Debug state

Table C3-6 shows the Debug state instructions.

Table C3-6 Debug state instructions

Mnemonic	Instruction	See
DCPS1	Debug switch to Exception level 1	*DCPS1* on page C6-461
DCPS2	Debug switch to Exception level 2	*DCPS2* on page C6-462
DCPS3	Debug switch to Exception level 3	*DCPS3* on page C6-463
DRPS	Debug restore PE state	*DRPS* on page C6-466

C3.1.5 System register instructions

For detailed information about the System register instructions, see Chapter C5 *The A64 System Instruction Class*. Table C3-7 shows the System register instructions.

Table C3-7 System register instructions

Mnemonic	Instruction	See
MRS	Move system register to general-purpose register	*MRS* on page C6-605
MSR	• Move general-purpose register to system register • Move immediate to PE state field	• *MSR (register)* on page C6-608 • *MSR (immediate)* on page C6-606

C3.1.6 System instructions

For detailed information about the System instructions, see Chapter C5 *The A64 System Instruction Class*.

Table C3-8 shows the System instructions.

Table C3-8 System instructions

Mnemonic	Instruction	See
SYS	System instruction	*SYS* on page C6-747
SYSL	System instruction with result	*SYSL* on page C6-748
IC	Instruction cache maintenance	*IC* on page C6-481 and Table C5-2 on page C5-239

Table C3-8 System instructions (continued)

Mnemonic	Instruction	See
DC	Data cache maintenance	*DC* on page C6-460 and Table C5-2 on page C5-239
AT	Address translation	*AT* on page C6-414 and Table C5-3 on page C5-239
TLBI	TLB Invalidate	*TLBI* on page C6-751 and Table C5-4 on page C5-240

C3.1.7 Hint instructions

Table C3-9 shows the Hint instructions.

Table C3-9 Hint instructions

Mnemonic	Instruction	See
NOP	No operation	*NOP* on page C6-617
YIELD	Yield hint	*YIELD* on page C6-768.
WFE	Wait for event	*WFE* on page C6-766.
WFI	Wait for interrupt	*WFI* on page C6-767
SEV	Send event	*SEV* on page C6-655
SEVL	Send event local	*SEVL* on page C6-656
HINT	Unallocated hint	*HINT* on page C6-477

C3.1.8 Barriers and CLREX instructions

Table C3-10 shows the barrier and CLREX instructions.

Table C3-10 Barriers and CLREX instructions

Mnemonic	Instruction	See
CLREX	Clear exclusive monitor	*CLREX* on page C6-437
DSB	Data synchronization barrier	*DSB* on page C6-467
DMB	Data memory barrier	*DMB* on page C6-464
ISB	Instruction synchronization barrier	*ISB* on page C6-482

Table C3-11 shows the allocated options for the data barriers. If an unallocated value is used in the option field, the instruction behaves as SY, but unallocated values might be allocated to other barrier functionality in future revisions of the architecture.

Table C3-11 Allocated values for the data barriers

Option	Shareability Domain	Ordered-accesses (before-after)
OSHLD	Outer Shareable	Load-Load/Store
OSHST		Store-Store
OSH		Any-Any

Table C3-11 Allocated values for the data barriers (continued)

Option	Shareability Domain	Ordered-accesses (before-after)
NSHLD	Non-shareable	Load-Load/Store
NSHST		Store-Store
NSH		Any-Any
ISHLD	Inner Shareable	Load-Load/Store
ISHST		Store-Store
ISH		Any-Any
LD	Full System	Load-Load/Store
ST		Store-Store
SY		Any-Any

C3.2 Loads and stores

This section describes the Load/Store instructions. It contains the following subsections:

- *Load/Store register*.
- *Load/Store register (unscaled offset)* on page C3-132.
- *Load/Store Pair* on page C3-133.
- *Load/Store Non-temporal Pair* on page C3-134.
- *Load/Store Unprivileged* on page C3-134.
- *Load-Exclusive/Store-Exclusive* on page C3-135.
- *Load-Acquire/Store-Release* on page C3-136.
- *Load/Store scalar SIMD and floating-point* on page C3-136.
- *Load/Store Vector* on page C3-139.
- *Prefetch memory* on page C3-140.

Apart from Load-Exclusive, Store-Exclusive, Load-Acquire, and Store-Release, addresses can have any alignment unless strict alignment checking is enabled, that is if SCTLR_ELx.A == 1.

The additional control bits SCTLR_ELx.SA and SCTLR_EL1.SA0 control whether the stack pointer must be quadword aligned when used as a base register. See *Stack pointer alignment checking* on page D1-1416. Using a misaligned stack pointer generates a Stack Alignment exception.

For information about the encoding structure of the instructions in this instruction group, see *Loads and stores* on page C4-178.

Note

In some cases, Load/Store instructions can lead to CONSTRAINED UNPREDICTABLE behavior. See *Constraints on AArch64 state UNPREDICTABLE behaviors* on page AppxA-4856.

C3.2.1 Load/Store register

The Load/Store register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset, optionally scaled.
- Base plus a 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

See also *Load/Store addressing modes* on page C1-116.

If a Load instruction specifies writeback and the register being loaded is also the base register, then one of the following behaviors occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs the load using the specified addressing mode and the base register becomes UNKNOWN. In addition, if an exception occurs during the execution of such an instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store instruction performs a writeback and the register that is stored is also the base register, then one of the following behaviors occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.

- The instruction performs the store to the designated register using the specified addressing mode, but the value stored is UNKNOWN.

Table C3-12 shows the Load/Store Register instructions.

Table C3-12 Load/Store register instructions

Mnemonic	Instruction	See
LDR	• Load register (register offset) • Load register (immediate offset) • Load register (PC-relative literal)	• *LDR (register)* on page C6-516 • *LDR (immediate)* on page C6-512 • *LDR (literal)* on page C6-515
LDRB	• Load byte (register offset) • Load byte (immediate offset)	• *LDRB (register)* on page C6-522 • *LDRB (immediate)* on page C6-519
LDRSB	• Load signed byte (register offset) • Load signed byte (immediate offset)	• *LDRSB (register)* on page C6-534 • *LDRSB (immediate)* on page C6-531
LDRH	• Load halfword (register offset) • Load halfword (immediate offset)	• *LDRH (register)* on page C6-528 • *LDRH (immediate)* on page C6-525
LDRSH	• Load signed halfword (register offset) • Load signed halfword (immediate offset)	• *LDRSH (register)* on page C6-540 • *LDRSH (immediate)* on page C6-537
LDRSW	• Load signed word (register offset) • Load signed word (immediate offset) • Load signed word (PC-relative literal)	• *LDRSW (register)* on page C6-547 • *LDRSW (immediate)* on page C6-543 • *LDRSW (literal)* on page C6-546
STR	• Store register (register offset) • Store register (immediate offset)	• *STR (register)* on page C6-692 • *STR (immediate)* on page C6-689
STRB	• Store byte (register offset) • Store byte (immediate offset)	• *STRB (register)* on page C6-698 • *STRB (immediate)* on page C6-695
STRH	• Store halfword (register offset) • Store halfword (immediate offset)	• *STRH (register)* on page C6-704 • *STRH (immediate)* on page C6-701

C3.2.2 Load/Store register (unscaled offset)

The Load/Store register instructions with an unscaled offset support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-116.

The Load/Store register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store register instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset, because that can represent some offset values in the same range.

The ambiguous immediate offsets are byte offsets that are both:

- In the range 0-255, inclusive.
- Naturally aligned to the access size.

Other byte offsets in the range -256 to 255 inclusive are unambiguous. An assembler program translating a Load/Store instruction, for example LDR, is required to encode an unambiguous offset using the unscaled 9-bit offset form, and to encode an ambiguous offset using the scaled 12-bit offset form. A programmer might force the

generation of the unscaled 9-bit form by using one of the mnemonics in Table C3-13. ARM recommends that a disassembler outputs all unscaled 9-bit offset forms using one of these mnemonics, but unambiguous offsets can be output using a Load/Store single register mnemonic, for example, LDR.

Table C3-13 shows the Load/Store register instructions with an unscaled offset.

Table C3-13 Load/Store register (unscaled offset) instructions

Mnemonic	Instruction	See
LDUR	Load register (unscaled offset)	*LDUR* on page C6-562
LDURB	Load byte (unscaled offset)	*LDURB* on page C6-564
LDURSB	Load signed byte (unscaled offset)	*LDURSB* on page C6-568
LDURH	Load halfword (unscaled offset)	*LDURH* on page C6-566
LDURSH	Load signed halfword (unscaled offset)	*LDURSH* on page C6-570
LDURSW	Load signed word (unscaled offset)	*LDURSW* on page C6-572
STUR	Store register (unscaled offset)	*STUR* on page C6-713
STURB	Store byte (unscaled offset)	*STURB* on page C6-715
STURH	Store halfword (unscaled offset)	*STURH* on page C6-717

C3.2.3 Load/Store Pair

The Load/Store Pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-116.

If a Load Pair instruction specifies the same register for the two register that are being loaded, then one of the following behaviors occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

If a Load Pair instruction specifies writeback and one of the registers being loaded is also the base register, then one of the following behaviors occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode, and the base register becomes UNKNOWN. In addition, if an exception occurs during the instruction, the base address might be corrupted so that the instruction cannot be repeated.

If a Store Pair instruction performs a writeback and one of the registers being stored is also the base register, then one of the following behaviors occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.

- The instruction performs all the stores of the registers indicated by the specified addressing mode, but the value stored for the base register is UNKNOWN.

Table C3-14 shows the Load/Store Pair instructions.

Table C3-14 Load/Store Pair instructions

Mnemonic	Instruction	See
LDP	Load Pair	*LDP* on page C6-506
LDPSW	Load Pair signed words	*LDPSW* on page C6-509
STP	Store Pair	*STP* on page C6-686

C3.2.4 Load/Store Non-temporal Pair

The Load/Store Non-temporal Pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-116.

The Load/Store Non-temporal Pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition there is a special exception to the normal memory ordering rules. If an address dependency exists between two memory reads, and a Load Non-temporal Pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, the memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-Temporal Pair instruction specifies the same register for the two registers that are being loaded, then one of the following can occur:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-15 shows the Load/Store Non-temporal Pair instructions.

Table C3-15 Load/Store Non-temporal Pair instructions

Mnemonic	Instruction	See
LDNP	Load Non-temporal Pair	*LDNP* on page C6-504
STNP	Store Non-temporal Pair	*STNP* on page C6-684

C3.2.5 Load/Store Unprivileged

The Load/Store Unprivileged instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See *Load/Store addressing modes* on page C1-116.

The Load/Store Unprivileged instructions can be used when the PE is at EL1 to perform unprivileged memory accesses. If the PE is executing in any other Exception level, then a normal memory access for that level is performed.

Table C3-16 shows the Load/Store Unprivileged instructions.

Table C3-16 Load-Store Unprivileged instructions

Mnemonic	Instruction	See
LDTR	Load Unprivileged register	*LDTR* on page C6-550
LDTRB	Load Unprivileged byte	*LDTRB* on page C6-552
LDTRSB	Load Unprivileged signed byte	*LDTRSB* on page C6-556
LDTRH	Load Unprivileged halfword	*LDTRH* on page C6-554
LDTRSH	Load Unprivileged signed halfword	*LDTRSH* on page C6-558
LDTRSW	Load Unprivileged signed word	*LDTRSW* on page C6-560
STTR	Store Unprivileged register	*STTR* on page C6-707
STTRB	Store Unprivileged byte	*STTRB* on page C6-709
STTRH	Store Unprivileged halfword	*STTRH* on page C6-711

C3.2.6 Load-Exclusive/Store-Exclusive

The Load-Exclusive/Store-Exclusive instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-116.

The Load-Exclusive instructions mark the physical address being accessed as an exclusive access. This exclusive access mark is checked by the Store-Exclusive instruction, permitting the construction of atomic read-modify-write operations on shared memory variables, semaphores, mutexes, and spinlocks. See *Load-Acquire Exclusive, Store-Release Exclusive and barriers* on page AppxF-4919.

Natural alignment is required and an unaligned address generates an Alignment fault. Memory accesses generated by Load-Exclusive pair or Store-Exclusive pair instructions must be aligned to the size of the pair. When a Store-Exclusive pair succeeds, it causes a single-copy atomic update of the entire memory location.

Table C3-17 shows the Load-Exclusive/Store-Exclusive instructions.

Table C3-17 Load-Exclusive/Store-Exclusive instructions

Mnemonic	Instruction	See
LDXR	Load Exclusive register	*LDXR* on page C6-577
LDXRB	Load Exclusive byte	*LDXRB* on page C6-580
LDXRH	Load Exclusive halfword	*LDXRH* on page C6-583
LDXP	Load Exclusive pair	*LDXP* on page C6-574
STXR	Store Exclusive register	*STXR* on page C6-722
STXRB	Store Exclusive byte	*STXRB* on page C6-725.
STXRH	Store Exclusive halfword	*STXRH* on page C6-728
STXP	Store Exclusive pair	*STXP* on page C6-719

C3.2.7 Load-Acquire/Store-Release

The Load-Acquire/Store-Release instructions support only one addressing mode:

- Base register with no offset.

See *Load/Store addressing modes* on page C1-116.

The Load-Acquire/Store-Release instructions can remove the requirement to use the explicit DMB memory barrier instruction. For more information about the ordering of Load-Acquire/Store-Release, see *Load-Acquire, Store-Release* on page B2-87.

Table C3-18 shows the Non-exclusive Load-Acquire/Store-Release instructions.

Table C3-18 Non-exclusive Load-Acquire and Store-Release instructions

STLXRB	Store-Release Exclusive byte	*STLXRB* on page C6-678.
STLXRH	Store-Release Exclusive halfword	*STLXRH* on page C6-681
STLXP	Store-Release Exclusive pair	*STLXP* on page C6-672

C3.2.8 Load/Store scalar SIMD and floating-point

The Load/Store scalar SIMD and floating-point instructions operate on scalar values in the SIMD and floating-point register file as described in *SIMD and floating-point scalar register names* on page C1-114. The memory addressing modes available, described in *Load/Store addressing modes* on page C1-116, are identical to the general-purpose register Load/Store instructions, and like those instructions permit arbitrary address alignment unless strict alignment checking is enabled. However, unlike the Load/Store instructions that transfer general-purpose registers, Load/Store scalar SIMD and floating-point instructions make no guarantee of atomicity, even when the address is naturally aligned to the size of the data.

Load/Store scalar SIMD and floating-point register

The Load/Store scalar SIMD and floating-point register instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus unscaled 9-bit signed immediate offset.
- Base plus 64-bit register offset, optionally scaled.
- Base plus 32-bit extended register offset, optionally scaled.
- Pre-indexed by an unscaled 9-bit signed immediate offset.
- Post-indexed by an unscaled 9-bit signed immediate offset.
- PC-relative literal for loads of 32 bits or more.

For more information on the addressing modes, see *Load/Store addressing modes* on page C1-116.

Note

The unscaled 9-bit signed immediate offset address mode requires its own instruction form, see *Load/Store scalar SIMD and floating-point register (unscaled offset)*.

Table C3-20 shows the Load/Store instructions for a single SIMD and floating-point register.

Table C3-20 Load/Store single SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDR	• Load scalar SIMD&FP register (register offset) • Load scalar SIMD&FP register (immediate offset) • Load scalar SIMD &FP register (PC-relative literal)	• *LDR (register, SIMD&FP)* on page C7-1054 • *LDR (immediate, SIMD&FP)* on page C7-1050 • *LDR (literal, SIMD&FP)* on page C7-1053
STR	• Store scalar SIMD &FP register (register offset) • Store scalar SIMD &FP register (immediate offset)	• *STR (register, SIMD&FP)* on page C7-1283 • *STR (immediate, SIMD&FP)* on page C7-1280

Load/Store scalar SIMD and floating-point register (unscaled offset)

The Load /Store scalar SIMD and floating-point register instructions support only one addressing mode:

- Base plus an unscaled 9-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-116.

The Load/Store scalar SIMD and floating-point register (unscaled offset) instructions are required to disambiguate this instruction class from the Load/Store single SIMD and floating-point instruction forms that support an addressing mode of base plus a scaled, unsigned 12-bit immediate offset. This is similar to the Load/Store register (unscaled offset) instructions, that disambiguate this instruction class from the Load/Store register instruction, see *Load/Store register (unscaled offset)* on page C3-132.

Table C3-21 shows the Load/Store SIMD and floating-point register instructions with an unscaled offset.

Table C3-21 Load/Store SIMD and floating-point register instructions

Mnemonic	Instruction	See
LDUR	Load scalar SIMD&FP register (unscaled offset)	*LDUR (SIMD&FP)* on page C7-1057
STUR	Store scalar SIMD&FP register (unscaled offset)	*STUR (SIMD&FP)* on page C7-1286

Load/Store SIMD and Floating-point register pair

The Load/Store SIMD and floating-point register pair instructions support the following addressing modes:

- Base plus a scaled 7-bit signed immediate offset.
- Pre-indexed by a scaled 7-bit signed immediate offset.
- Post-indexed by a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-116.

If a Load pair instruction specifies the same register for the two registers that are being loaded, then one of the following occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs all of the loads using the specified addressing mode and the register being loaded takes an UNKNOWN value.

Table C3-22 shows the Load/Store SIMD and floating-point register pair instructions.

Table C3-22 Load/Store SIMD and floating-point register pair instructions

Mnemonic	Instruction	See
LDP	Load pair of scalar SIMD&FP registers	*LDP (SIMD&FP)* on page C7-1047
STP	Store pair of scalar SIMD&FP registers	*STP (SIMD&FP)* on page C7-1277

Load/Store SIMD and Floating-point Non-temporal pair

The Load/Store SIMD and Floating-point Non-temporal pair instructions support only one addressing mode:

- Base plus a scaled 7-bit signed immediate offset.

See also *Load/Store addressing modes* on page C1-116.

The Load/Store Non-temporal pair instructions provide a hint to the memory system that an access is non-temporal or streaming, and unlikely to be repeated in the near future. This means that data caching is not required. However, depending on the memory type, the instructions might permit memory reads to be preloaded and memory writes to be gathered to accelerate bulk memory transfers.

In addition there is a special exception to the normal memory ordering rules. If an address dependency exists between two memory reads, and a Load non-temporal pair instruction generated the second read, then in the absence of any other barrier mechanism to achieve order, those memory accesses can be observed in any order by the other observers within the shareability domain of the memory addresses being accessed.

If a Load Non-temporal pair instruction specifies the same register for the two registers that are being loaded, then one of the following occurs:

- The instruction is treated as unallocated.
- The instruction is treated as a NOP.
- The instruction performs all the loads using the specified addressing mode and the register that is loaded takes an UNKNOWN value.

Table C3-23 shows the Load/Store SIMD and floating-point Non-temporal pair instructions.

Table C3-23 Load/Store SIMD and floating-point Non-temporal pair instructions

Mnemonic	Instruction	See
LDNP	Load pair of scalar SIMD&FP registers	*LDNP (SIMD&FP)* on page C7-1045
STNP	Store pair of scalar SIMD&FP registers	*STNP (SIMD&FP)* on page C7-1275

C3.2.9 Load/Store Vector

The Vector Load/Store structure instructions support the following addressing modes:

- Base register only.
- Post-indexed by a 64-bit register.
- Post-indexed by an immediate, equal to the number of bytes transferred.

Load/Store vector instructions, like other Load/Store instructions, allow any address alignment, unless strict alignment checking is enabled. If strict alignment checking is enabled, then alignment checking to the size of the element is performed. However, unlike the Load/Store instructions that transfer general-purpose registers, the Load/Store vector instructions do not guarantee atomicity, even when the address is naturally aligned to the size of the element.

Load/Store structures

Table C3-24 shows the Load/Store structure instructions. A post-increment immediate offset, if present, must be 8, 16, 24, 32, 48, or 64, depending on the number of elements transferred.

Table C3-24 Load/Store multiple structures instructions

Mnemonic	Instruction	See
LD1	• Load single 1-element structure to one lane of one register • Load multiple 1-element structures to one register or to two, three or four consecutive registers	• *LD1 (single structure)* on page C7-1012 • *LD1 (multiple structures)* on page C7-1009
LD2	• Load single 2-element structure to one lane of two consecutive registers • Load multiple 2-element structures to two consecutive registers	• *LD2 (single structure)* on page C7-1021 • *LD2 (multiple structures)* on page C7-1018
LD3	• Load single 3-element structure to one lane of three consecutive registers • Load multiple 3-element structures to three consecutive registers	• *LD3 (single structure)* on page C7-1030 • *LD3 (multiple structures)* on page C7-1027
LD4	• Load single 4-element structure to one lane of four consecutive registers • Load multiple 4-element structures to four consecutive registers	• *LD4 (single structure)* on page C7-1039 • *LD4 (multiple structures)* on page C7-1036
ST1	• Store single 1-element structure from one lane of one register • Store multiple 1-element structures from one register, or from two, three or four consecutive registers	• *ST1 (single structure)* on page C7-1254 • *ST1 (multiple structures)* on page C7-1251

Table C3-24 Load/Store multiple structures instructions (continued)

Mnemonic	Instruction	See
ST2	• Store single 2-element structure from one lane of two consecutive registers • Store multiple 2-element structures from two consecutive registers	• *ST2 (single structure)* on page C7-1260 • *ST2 (multiple structures)* on page C7-1257
ST3	• Store single 3-element structure from one lane of three consecutive registers • Store multiple 3-element structures from three consecutive registers	• *ST3 (single structure)* on page C7-1266 • *ST3 (multiple structures)* on page C7-1263
ST4	• Store single 4-element structure from one lane of four consecutive registers • Store multiple 4-element structures from four consecutive registers	• *ST4 (single structure)* on page C7-1272 • *ST4 (multiple structures)* on page C7-1269

Load single structure and replicate

Table C3-25 shows the Load single structure and replicate instructions. A post-increment immediate offset, if present, must be 1, 2, 3, 4, 6, 8, 12, 16, 24, or 32, depending on the number of elements transferred.

Table C3-25 Load single structure and replicate instructions

Mnemonic	Instruction	See
LD1R	Load single 1-element structure and replicate to all lanes of one register	*LD1R* on page C7-1015
LD2R	Load single 2-element structure and replicate to all lanes of two registers	*LD2R* on page C7-1024
LD3R	Load single 3-element structure and replicate to all lanes of three registers	*LD3R* on page C7-1033
LD4R	Load single 4-element structure and replicate to all lanes of four registers	*LD4R* on page C7-1042

C3.2.10 Prefetch memory

The Prefetch memory instructions support the following addressing modes:

- Base plus a scaled 12-bit unsigned immediate offset or base plus an unscaled 9-bit signed immediate offset.
- Base plus a 64-bit register offset. This can be optionally scaled by 8-bits, for example LSL#3.
- Base plus a 32-bit extended register offset. This can be optionally scaled by 8-bits.
- PC-relative literal.

The prefetch memory instructions signal to the memory system that memory accesses from a specified address are likely to occur in the near future. The memory system can respond by taking actions that are expected to speed up the memory access when they do occur, such as pre-loading the specified address into one or more caches. Because these signals are only hints, it is valid for the PE to treat any or all prefetch instructions as a NOP.

Because they are hints to the memory system, the operation of a PRFM instruction cannot cause a synchronous exception. However, a memory operation performed as a result of one of these memory system hints might in exceptional cases trigger an asynchronous event, and thereby influence the execution of the PE. An example of an asynchronous event that might be triggered is a SError interrupt.

A PRFM instruction can only have an effect on software visible structures, such as caches and translation lookaside buffers associated with memory locations that can be accessed by reads, writes, or execution as defined in the translation regime of the current Exception level.

A PRFM instruction is guaranteed not to access Device memory.

A PRFM instruction using a PLI hint must not result in any access that could not be performed by the PE speculatively fetching an instruction. Therefore, if all associated MMUs are disabled, a PLI hint cannot access any memory location that cannot be accessed by instruction fetches.

The PRFM instructions require an additional <prfop> operand to be specified, which must be one of the following:

```
PLDL1KEEP, PLDL1STRM, PLDL2KEEP, PLDL2STRM, PLDL3KEEP, PLDL3STRM

PSTL1KEEP, PSTL1STRM, PSTL2KEEP, PSTL2STRM, PSTL3KEEP, PSTL3STRM

PLIL1KEEP, PLIL1STRM, PLIL2KEEP, PLIL2STRM, PLIL3KEEP, PLIL3STRM
```

<prfop> is defined as <type><target><policy>.

Here:

<type>	Is one of:	
	PLD	Prefetch for load.
	PST	Prefetch for store.
	PLI	Preload instructions.
<target>	Is one of:	
	L1	Level 1 cache.
	L2	Level 2 cache.
	L3	Level 3 cache.
<policy>	Is one of:	
	KEEP	Retained or temporal prefetch, allocated in the cache normally.
	STRM	Streaming or non-temporal prefetch, for data that is used only once.

PRFUM explicitly uses the unscaled 9-bit signed immediate offset addressing mode, as described in *Load/Store register (unscaled offset)* on page C3-132.

Table C3-26 shows the Prefetch memory instructions.

Table C3-26 Prefetch memory instructions

Mnemonic	Instruction	See
PRFM	• Prefetch memory (register offset) • Prefetch memory (immediate offset) • Prefetch memory (PC-relative offset)	• *PRFM (register)* on page C6-629 • *PRFM (immediate)* on page C6-624 • *PRFM (literal)* on page C6-627
PRFUM	Prefetch memory (unscaled offset)	*PRFUM* on page C6-632

C3.3 Data processing - immediate

This section describes the instruction groups for data processing with immediate operands. It contains the following subsections:

- *Arithmetic (immediate)*.
- *Logical (immediate)*.
- *Move (wide immediate)* on page C3-143.
- *Move (immediate)* on page C3-143.
- *PC-relative address calculation* on page C3-144.
- *Bitfield move* on page C3-144.
- *Bitfield insert and extract* on page C3-145
- *Extract register* on page C3-145.
- *Shift (immediate)* on page C3-145.
- *Sign-extend and Zero-extend* on page C3-145.

For information about the encoding structure of the instructions in this instruction group, see *Data processing - immediate* on page C4-195.

C3.3.1 Arithmetic (immediate)

The Arithmetic (immediate) instructions accept a 12-bit unsigned immediate value, optionally shifted left by 12 bits.

The Arithmetic (immediate) instructions that do not set condition flags can read from and write to the current stack pointer. The flag setting instructions can read from the stack pointer, but they cannot write to it.

Table C3-27 shows the Arithmetic instructions with an immediate offset.

Table C3-27 Arithmetic instructions with an immediate

Mnemonic	Instruction	See
ADD	Add	*ADD (immediate)* on page C6-392
ADDS	Add and set flags	*ADDS (immediate)* on page C6-398
SUB	Subtract	*SUB (immediate)* on page C6-733
SUBS	Subtract and set flags	*SUBS (immediate)* on page C6-739
CMP	Compare	*CMP (immediate)* on page C6-446.
CMN	Compare negative	*CMN (immediate)* on page C6-442

C3.3.2 Logical (immediate)

The Logical (immediate) instructions accept a bitmask immediate value that is a 32-bit pattern or a 64-bit pattern viewed as a vector of identical elements of size e = 2, 4, 8, 16, 32 or, 64 bits. Each element contains the same sub-pattern, that is a single run of 1 to (e - 1) nonzero bits from bit 0 followed by zero bits, then rotated by 0 to (e - 1) bits. This mechanism can generate 5334 unique 64-bit patterns as 2667 pairs of pattern and their bitwise inverse.

Note

Values that consist of only zeros or only ones cannot be described in this way.

The Logical (immediate) instructions that do not set the condition flags can write to the current stack pointer, for example to align the stack pointer in a function prologue.

Note

Apart from ANDS, and its TST alias, Logical (immediate) instructions do not set the condition flags. However, the final results of a bitwise operation can be tested by a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-28 shows the Logical immediate instructions.

Table C3-28 Logical immediate instructions

Mnemonic	Instruction	See
AND	Bitwise AND	*AND (immediate)* on page C6-404
ANDS	Bitwise AND and set flags	*ANDS (immediate)* on page C6-407
EOR	Bitwise exclusive OR	*EOR (immediate)* on page C6-471
ORR	Bitwise inclusive OR	*ORR (immediate)* on page C6-620
TST	Test bits	*TST (immediate)* on page C6-752

C3.3.3 Move (wide immediate)

The Move (wide immediate) instructions insert a 16-bit immediate, or inverted immediate, into a 16-bit aligned position in the destination register. The value of the other bits in the destination register depends on the variant used. The optional shift amount can be any multiple of 16 that is smaller than the register size.

Table C3-29 shows the Move (wide immediate) instructions.

Table C3-29 Move (wide immediate) instructions

Mnemonic	Instruction	See
MOVZ	Move wide with zero	*MOVZ* on page C6-603
MOVN	Move wide with NOT	*MOVN* on page C6-601
MOVK	Move wide with keep	*MOVK* on page C6-600

C3.3.4 Move (immediate)

The Move (immediate) instructions are aliases for a single MOVZ, MOVN, or ORR (immediate with zero register), instruction to load an immediate value into the destination register. An assembler must permit a signed or unsigned immediate, as long as its binary representation can be generated using one of these instructions, and an assembler error results if the immediate cannot be generated in this way. On disassembly it is unspecified whether the immediate is output as a signed or an unsigned value.

If there is a choice between the MOVZ, MOVN, and ORR instruction to encode the immediate, then an assembler must prefer MOVZ to MOVN, and MOVZ or MOVN to ORR, to ensure reversability. A disassembler must output ORR (immediate with zero register) MOVZ, and MOVN, as a MOV mnemonic except that the underlying instruction must be used when:

- ORR has an immediate that can be generated by a MOVZ or MOVN instruction.
- A MOVN instruction has an immediate that can be encoded by MOVZ.
- MOVZ #0 or MOVN #0 have a shift amount other than LSL #0.

Table C3-30 shows the Move (immediate) instructions.

Table C3-30 Move (immediate) instructions

Mnemonic	Instruction	See
MOV	• Move (inverted wide immediate) • Move (wide immediate) • Move (bitmask immediate)	• *MOV (inverted wide immediate)* on page C6-596 • *MOV (wide immediate)* on page C6-597 • *MOV (bitmask immediate)* on page C6-598

C3.3.5 PC-relative address calculation

The ADR instruction adds a signed, 21-bit immediate to the value of the program counter that fetched this instruction, and then writes the result to a general-purpose register. This permits the calculation of any byte address within ±1MB of the current PC.

The ADRP instruction shifts a signed, 21-bit immediate left by 12 bits, adds it to the value of the program counter with the bottom 12 bits cleared to zero, and then writes the result to a general-purpose register. This permits the calculation of the address at a 4KB aligned memory region. In conjunction with an ADD (immediate) instruction, or a Load/Store instruction with a 12-bit immediate offset, this allows for the calculation of, or access to, any address within ±4GB of the current PC.

Note

The term *page* used in the ADRP description is short-hand for the 4KB memory region, and is not related to the virtual memory translation granule size.

Table C3-31 shows the instructions used for PC-relative address calculations are as follows:

Table C3-31 PC-relative address calculation instructions

Mnemonic	Instruction	See
ADRP	Compute address of 4KB page at a PC-relative offset	*ADRP* on page C6-403
ADR	Compute address of label at a PC-relative offset.	*ADR* on page C6-402

C3.3.6 Bitfield move

The Bitfield move instructions copy a bitfield of constant width from bit 0 in the source register to a constant bit position in the destination register, or from a constant bit position in the source register to bit 0 in the destination register. The remaining bits in the destination register are set as follows:

- For BFM the remaining bits are unchanged.
- For UBFM the lower bits, if any, and upper bits, if any, are set to zero.
- For SBFM the lower bits, if any, are set to zero, and the upper bits, if any, are set to a copy of the most-significant bit in the copied bitfield.

Table C3-32 shows the Bitfield move instructions.

Table C3-32 Bitfield move instructions

Mnemonic	Instruction	See
BFM	Bitfield move	*BFM* on page C6-418
SBFM	Signed bitfield move	*SBFM* on page C6-651
UBFM	Unsigned bitfield move (32-bit)	*UBFM* on page C6-755

C3.3.7 Bitfield insert and extract

The Bitfield insert and extract instructions are implemented as aliases of the Bitfield move instructions. Table C3-33 shows the Bitfield insert and extract aliases.

Table C3-33 Bitfield insert and extract instructions

Mnemonic	Instruction	See
BFI	Bitfield insert	*BFI* on page C6-417
BFXIL	Bitfield extract and insert low	*BFXIL* on page C6-420
SBFIZ	Signed bitfield insert in zero	*SBFIZ* on page C6-650
SBFX	Signed bitfield extract	*SBFX* on page C6-653
UBFIZ	Unsigned bitfield insert in zero	*UBFIZ* on page C6-754
UBFX	Unsigned bitfield extract	*UBFX* on page C6-757

C3.3.8 Extract register

Depending on the register width of the operands, the Extract register instruction copies a 32-bit or 64-bit field from a constant bit position within a double-width value formed by the concatenation of a pair of source registers to a destination register.

Table C3-34 shows the Extract (immediate) instructions.

Table C3-34 Extract register instructions

Mnemonic	Instruction	See
EXTR	Extract register from pair	*EXTR* on page C6-475

C3.3.9 Shift (immediate)

Shifts and rotates by a constant amount are implemented as aliases of the Bitfield move or Extract register instructions. The shift or rotate amount must be in the range 0 to one less than the register width of the instruction, inclusive.

Table C3-35 shows the aliases that can be used as immediate shift and rotate instructions.

Table C3-35 Aliases for immediate shift and rotate instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	*ASR (immediate)* on page C6-412
LSL	Logical shift left	*LSL (immediate)* on page C6-587
LSR	Logical shift right	*LSR (immediate)* on page C6-590
ROR	Rotate right	*ROR (immediate)* on page C6-643

C3.3.10 Sign-extend and Zero-extend

The Sign-extend and Zero-extend instructions are implemented as aliases of the Bitfield move instructions.

Table C3-36 on page C3-146 shows the aliases that can be used as zero-extend and sign-extend instructions.

Table C3-36 Zero-extend and sign-extend instructions

Mnemonic	Instruction	See
SXTB	Sign-extend byte	*SXTB* on page C6-744
SXTH	Sign-extend halfword	*SXTH* on page C6-745
SXTW	Sign-extend word	*SXTW* on page C6-746
UXTB	Unsigned extend byte	*UXTB* on page C6-764
UXTH	Unsigned extend halfword	*UXTH* on page C6-765

C3.4 Data processing - register

This section describes the instruction groups for data processing with all register operands. It contains the following subsections:

- *Arithmetic (shifted register)*.
- *Arithmetic (extended register)*.
- *Arithmetic with carry* on page C3-148.
- *Logical (shifted register)* on page C3-149.
- *Move (register)* on page C3-150.
- *Shift (register)* on page C3-150.
- *Multiply and divide* on page C3-150.
- *CRC32* on page C3-152.
- *Bit operation* on page C3-152.
- *Conditional select* on page C3-152.
- *Conditional comparison* on page C3-153.

For information about the encoding structure of the instructions in this instruction group, see *Data processing - register* on page C4-198.

C3.4.1 Arithmetic (shifted register)

The Arithmetic (shifted register) instructions apply an optional shift operator to the second source register value before performing the arithmetic operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators `LSL`, `ASR` and `LSR` accept an immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator implies `LSL #0`, which means that there is no shift. A disassembler must not output `LSL #0`. However, a disassembler must output all other shifts by zero.

The current stack pointer, SP or WSP, cannot be used with this class of instructions. See *Arithmetic (extended register)* for arithmetic instructions that can operate on the current stack pointer.

Table C3-37 shows the Arithmetic (shifted register) instructions.

Table C3-37 Arithmetic (shifted register) instructions

Mnemonic	Instruction	See
ADD	Add	*ADD (shifted register)* on page C6-394
ADDS	Add and set flags	*ADDS (shifted register)* on page C6-400
SUB	Subtract	*SUB (shifted register)* on page C6-735
SUBS	Subtract and set flags	*SUBS (shifted register)* on page C6-741
CMN	Compare negative	*CMN (shifted register)* on page C6-443
CMP	Compare	*CMP (shifted register)* on page C6-447
NEG	Negate	*NEG* on page C6-613
NEGS	Negate and set flags	*NEGS* on page C6-614

C3.4.2 Arithmetic (extended register)

The extended register instructions provide an optional sign-extension or zero-extension of a portion of the second source register value, followed by an optional left shift by a constant amount of 1-4, inclusive.

The extended shift is described by the mandatory extend operator SXTB, SXTH, SXTW, UXTB, UXTH,or UXTW. This is followed by an optional left shift amount. If the shift amount is not specified, the default shift amount is zero. A disassembler must not output a shift amount of zero.

For 64-bit instruction forms the additional operators UXTX and SXTX use all 64 bits of the second source register with an optional shift. In that case ARM recommends UXTX as the operator. If and only if at least one register is SP, ARM recommends use of the LSL operator name, rather than UXTX, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

For 32-bit instruction forms the operators UXTW and SXTW both use all 32 bits of the second source register with an optional shift. In that case ARM recommends UXTW as the operator. If and only if at least one register is WSP, ARM recommends use of the LSL operator name, rather than UXTW, and when the shift amount is also zero then both the operator and the shift amount can be omitted.

The non-flag setting variants of the extended register instruction permit the use of the current stack pointer as either the destination register and the first source register. The flag setting variants only permit the stack pointer to be used as the first source register.

In the 64-bit form of these instructions the final register operand is written as Wm for all except the UXTX/LSL and SXTX extend operators. For example:

```
CMP X4, W5, SXTW
ADD X1, X2, W3, UXTB #2
SUB SP, SP, X1              // SUB SP, SP, X1, UXTX #0
```

Table C3-38 shows the Arithmetic (extended register) instructions.

Table C3-38 Arithmetic (extended register) instructions

Mnemonic	Instruction	See
ADD	Add	*ADD (extended register)* on page C6-390
ADDS	Add and set flags	*ADDS (extended register)* on page C6-396
SUB	Subtract	*SUB (extended register)* on page C6-731
SUBS	Subtract and set flags	*SUBS (extended register)* on page C6-737
CMN	Compare negative	*CMN (extended register)* on page C6-440
CMP	Compare	*CMP (extended register)* on page C6-444

C3.4.3 Arithmetic with carry

The Arithmetic with carry instructions accept two source registers, with the carry flag as an additional input to the calculation. They do not support shifting of the second source register.

Table C3-39 shows the Arithmetic with carry instructions

Table C3-39 Arithmetic with carry instructions

Mnemonic	Instruction	See
ADC	Add with carry	*ADC* on page C6-388
ADCS	Add with carry and set flags	*ADCS* on page C6-389
SBC	Subtract with carry	*SBC* on page C6-646

Table C3-39 Arithmetic with carry instructions (continued)

Mnemonic	Instruction	See
SBCS	Subtract with carry and set flags	*SBCS* on page C6-648
NGC	Negate with carry	*NGC* on page C6-615
NGCS	Negate with carry and set flags	*NGCS* on page C6-616

C3.4.4 Logical (shifted register)

The Logical (shifted register) instructions apply an optional shift operator to the second source register value before performing the main operation. The register width of the instruction controls whether the new bits are fed into the intermediate result on a right shift or rotate at bit[63] or bit[31].

The shift operators LSL, ASR, LSR and ROR accept a constant immediate shift amount in the range 0 to one less than the register width of the instruction, inclusive.

Omitting the shift operator and amount implies LSL #0, which means that there is no shift. A disassembler must not output LSL #0. However, a disassembler must output all other shifts by zero.

Note

Apart from ANDS,TST and BICS the logical instructions do not set the condition flags, but the final result of a bit operation can usually directly control a CBZ, CBNZ, TBZ, or TBNZ conditional branch.

Table C3-40 shows the Logical (shifted register) instructions.

Table C3-40 Logical (shifted register) instructions

Mnemonic	Instruction	See
AND	Bitwise AND	*AND (shifted register)* on page C6-405
ANDS	Bitwise AND and set flags	*ANDS (shifted register)* on page C6-409
BIC	Bitwise bit clear	*BIC (shifted register)* on page C6-421
BICS	Bitwise bit clear and set flags	*BICS (shifted register)* on page C6-423
EON	Bitwise exclusive OR NOT	*EON (shifted register)* on page C6-469
EOR	Bitwise exclusive OR	*EOR (shifted register)* on page C6-472
ORR	Bitwise inclusive OR	*ORR (shifted register)* on page C6-622
MVN	Bitwise NOT	*MVN* on page C6-612
ORN	Bitwise inclusive OR NOT	*ORN (shifted register)* on page C6-618
TST	Test bits	*TST (shifted register)* on page C6-753

C3.4.5 Move (register)

The Move (register) instructions are aliases for other data processing instructions. They copy a value from a general-purpose register to another general-purpose register or the current stack pointer, or from the current stack pointer to a general-purpose register.

Table C3-41 MOV register instructions

Mnemonic	Instruction	See
MOV	• Move register • Move register to SP or move SP to register	• *MOV (register)* on page C6-599 • *MOV (to/from SP)* on page C6-595

C3.4.6 Shift (register)

In the Shift (register) instructions, the shift amount is the positive value in the second source register modulo the register size. The register width of the instruction controls whether the new bits are fed into the result on a right shift or rotate at bit[63] or bit[31].

Table C3-42 shows the Shift (register) instructions.

Table C3-42 Shift (register) instructions

Mnemonic	Instruction	See
ASRV	Arithmetic shift right variable	*ASRV* on page C6-413
LSLV	Logical shift left variable	*LSLV* on page C6-588
LSRV	Logical shift right variable	*LSRV* on page C6-591
RORV	Rotate right variable	*RORV* on page C6-645

However, the Shift (register) instructions have a preferred set of aliases that match the shift immediate aliases described in *Shift (immediate)* on page C3-145.

Table C3-43 shows the aliases for Shift (register) instructions.

Table C3-43 Aliases for Variable shift instructions

Mnemonic	Instruction	See
ASR	Arithmetic shift right	*ASR (register)* on page C6-411
LSL	Logical shift left	*LSL (register)* on page C6-586
LSR	Logical shift right	*LSR (register)* on page C6-589
ROR	Rotate right	*ROR (register)* on page C6-644

C3.4.7 Multiply and divide

This section describes the instructions used for integer multiplication and division. It contains the following subsections:

- *Multiply* on page C3-151.
- *Divide* on page C3-151.

Multiply

The Multiply instructions write to a single 32-bit or 64-bit destination register, and are built around the fundamental four operand multiply-add and multiply-subtract operation, together with 32-bit to 64-bit widening variants. A 64-bit to 128-bit widening multiple can be constructed with two instructions, using `SMULH` or `UMULH` to generate the upper 64 bits. Table C3-44 shows the Multiply instructions.

Table C3-44 Multiply integer instructions

Mnemonic	Instruction	See
`MADD`	Multiply-add	*MADD* on page C6-592
`MSUB`	Multiply-subtract	*MSUB* on page C6-609
`MNEG`	Multiply-negate	*MNEG* on page C6-594
`MUL`	Multiply	*MUL* on page C6-611
`SMADDL`	Signed multiply-add long	*SMADDL* on page C6-657
`SMSUBL`	Signed multiply-subtract long	*SMSUBL* on page C6-660
`SMNEGL`	Signed multiply-negate long	*SMNEGL* on page C6-659
`SMULL`	Signed multiply long	*SMULL* on page C6-662
`SMULH`	Signed multiply high	*SMULH* on page C6-661
`UMADDL`	Unsigned multiply-add long	*UMADDL* on page C6-759.
`UMSUBL`	Unsigned multiply-subtract long	*UMSUBL* on page C6-761
`UMNEGL`	Unsigned multiply-negate long	*UMNEGL* on page C6-760
`UMULL`	Unsigned multiply long	*UMULL* on page C6-763
`UMULH`	Unsigned multiply high	*UMULH* on page C6-762

Divide

The Divide instructions compute the quotient of a division, rounded towards zero. The remainder can then be computed as (numerator - (quotient × denominator)), using the `MSUB` instruction.

If a signed integer division (`INT_MIN / -1`) is performed where `INT_MIN` is the most negative integer value representable in the selected register size, then the result overflows the signed integer range. No indication of this overflow is produced and the result that is written to the destination register is `INT_MIN`.

A division by zero results in a zero being written to the destination register, without any indication that the division by zero occurred.

Table C3-45 shows the Divide instructions.

Table C3-45 Divide instructions

Mnemonic	Instruction	See
`SDIV`	Signed divide	*SDIV* on page C6-654
`UDIV`	Unsigned divide	*UDIV* on page C6-758

C3.4.8 CRC32

The optional CRC32 instructions operate on the general-purpose register file to update a 32-bit CRC value from an input value comprising 1, 2, 4, or 8 bytes. There are two different classes of CRC instructions, CRC32 and CRC32C, that support two commonly used 32-bit polynomials, known as CRC-32 and CRC-32C.

To fit with common usage, the bit order of the values is reversed as part of the operation.

When bits[19:16] of ID_AA64ISAR0_EL1 are set to 0b0001 the CRC instructions are implemented.

Table C3-46 shows the CRC instructions.

Table C3-46 CRC32 instructions

Mnemonic	Instruction	See
CRC32B	CRC-32 sum from byte	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-449
CRC32H	CRC-32 sum from halfword	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-449
CRC32W	CRC-32 sum from word	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-449
CRC32X	CRC-32 sum from doubleword	*CRC32B, CRC32H, CRC32W, CRC32X* on page C6-449
CRC32CB	CRC-32C sum from byte	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-450
CRC32CH	CRC-32C sum from halfword	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-450
CRC32CW	CRC-32C sum from word	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-450
CRC32CX	CRC-32C sum from doubleword	*CRC32CB, CRC32CH, CRC32CW, CRC32CX* on page C6-450

C3.4.9 Bit operation

Table C3-47 shows the Bit operation instructions.

Table C3-47 Bit operation instructions

Mnemonic	Instruction	See
CLS	Count leading sign bits	*CLS* on page C6-438
CLZ	Count leading zero bits	*CLZ* on page C6-439
RBIT	Reverse bit order	*RBIT* on page C6-635
REV	Reverse bytes in register	*REV* on page C6-638.
REV16	Reverse bytes in halfwords	*REV16* on page C6-640
REV32	Reverses bytes in words	*REV32* on page C6-642

C3.4.10 Conditional select

The Conditional select instructions select between the first or second source register, depending on the current state of the condition flags. When the named condition is true, the first source register is selected and its value is copied without modification to the destination register. When the condition is false the second source register is selected and its value might not be optionally inverted, negated, or incremented by one, before writing to the destination register.

Other useful conditional set and conditional unary operations are implemented as aliases of the four Conditional select instructions.

Table C3-48 shows the Conditional select instructions.

Table C3-48 Conditional select instructions

Mnemonic	Instruction	See
CSEL	Conditional select	*CSEL* on page C6-451
CSINC	Conditional select increment	*CSINC* on page C6-454
CSINV	Conditional select inversion	*CSINV* on page C6-456
CSNEG	Conditional select negation	*CSNEG* on page C6-458
CSET	Conditional set	*CSET* on page C6-452
CSETM	Conditional set mask	*CSETM* on page C6-453
CINC	Conditional increment	*CINC* on page C6-435
CINV	Conditional invert	*CINV* on page C6-436
CNEG	Conditional negate	*CNEG* on page C6-448

C3.4.11 Conditional comparison

The Conditional comparison instructions provide a conditional select for the NZCV condition flags, setting the flags to the result of an arithmetic comparison of its two source register values if the named input condition is true, or to an immediate value if the input condition is false. There are register and immediate forms. The immediate form compares the source register to a small 5-bit unsigned value.

Table C3-49 shows the Conditional comparison instructions.

Table C3-49 Conditional comparison instructions

Mnemonic	Instruction	See
CCMN	Conditional compare negative (register)	*CCMN (register)* on page C6-432
CCMN	Conditional compare negative (immediate)	*CCMN (immediate)* on page C6-431
CCMP	Conditional compare (register)	*CCMP (register)* on page C6-434
CCMP	Conditional compare (immediate)	*CCMP (immediate)* on page C6-433

C3.5 Data processing - SIMD and floating-point

This section describes the instruction groups for data processing with SIMD and floating-point register operands.

It contains the following subsections that describe the scalar floating-point data processing instructions:

- *Floating-point move (register)* on page C3-155.
- *Floating-point move (immediate)* on page C3-155.
- *Floating-point conversion* on page C3-156.
- *Floating-point round to integral* on page C3-157.
- *Floating-point multiply-add* on page C3-158.
- *Floating-point arithmetic (one source)* on page C3-158.
- *Floating-point arithmetic (two sources)* on page C3-158.
- *Floating-point minimum and maximum* on page C3-158.
- *Floating-point comparison* on page C3-159.
- *Floating-point conditional select* on page C3-159.

It also contains the following subsections that describe the SIMD data processing instructions:

- *SIMD move* on page C3-160
- *SIMD arithmetic* on page C3-160.
- *SIMD compare* on page C3-162.
- *SIMD widening and narrowing arithmetic* on page C3-163.
- *SIMD unary arithmetic* on page C3-164.
- *SIMD by element arithmetic* on page C3-166.
- *SIMD permute* on page C3-167.
- *SIMD immediate* on page C3-167.
- *SIMD shift (immediate)* on page C3-168.
- *SIMD floating-point and integer conversion* on page C3-169.
- *SIMD reduce (across vector lanes)* on page C3-170.
- *SIMD pairwise arithmetic* on page C3-170.
- *SIMD table lookup* on page C3-171.
- *The Cryptographic Extensions* on page C3-171.

For information about the encoding structure of the instructions in this instruction group, see *Data processing - SIMD and floating point* on page C4-205.

For information about the Floating-point exceptions, see *Floating-point Exception traps* on page D1-1451.

C3.5.1 Common features of SIMD instructions

A number of SIMD instructions come in three forms:

- Wide:
  - This is indicated by the suffix *W*. The element width of the destination register and the first source operand is double that of the second source operand.
- Long:
  - This is indicated by the suffix *L*. The element width of the destination register is double that of both source operands.
- Narrow:
  - This is indicated by the suffix *N*. The element width of the destination register is half that of both source operands.

Furthermore, each vector form of the instruction is part of a pair, with a second and upper half suffix of *2*, to identify the variant of the instruction:

- Where a SIMD operation widens or lengthens a 64-bit vector to a 128-bit vector, the instruction provides a second part operation that can extract the source from the upper 64-bits of the source registers.
- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the instruction provides a second-part operation that can pack the result of a second operation into the upper part of the same destination register.

Note

This is referred to as a *lane set specifier*.

C3.5.2 Floating-point move (register)

The Floating-point move (register) instructions copy a scalar floating-point value from one register to another register without performing any conversion.

Some of the Floating-point move (register) instructions overlap with the functionality provided by the Advanced SIMD instructions `DUP`, `INS`, and `UMOV`. However, ARM recommends using the `FMOV` instructions when operating on scalar floating-point data to avoid the creation of scalar floating-point code that depends on the availability of the Advanced SIMD instruction set.

Table C3-50 shows the Floating-point move (register) instructions.

Table C3-50 Floating-point move (register) instructions

Mnemonic	Instruction	See
`FMOV`	• Floating-point move register without conversion • Floating-point move to or from general-purpose register without conversion	• *FMOV (register)* on page C7-955 • *FMOV (general)* on page C7-956

C3.5.3 Floating-point move (immediate)

The Floating-point move (immediate) instructions convert a small constant immediate floating-point value into a single-precision or double-precision scalar floating-point value in a SIMD and floating-point register.

The floating-point constant can be specified either in decimal notation, such as 12.0 or -1.2e1, or as a string beginning with `0x` followed by a hexadecimal representation of the IEEE 754 single-precision or double-precision encoding. ARM recommends that a disassembler uses the decimal notation, provided that this displays the value precisely.

The floating-point value must be expressible as $(\pm n/16 \times 2^r)$, where n is an integer in the range $16 \le n \le 31$ and r is an integer in the range of $-3 \le r \le 4$, that is a normalized binary floating-point encoding with one sign bit, four bits of fraction, and a 3-bit exponent.

Note

This encoding does not include the floating-point constant 0.0. There are several instructions that can store zero in a SIMD and floating-point register, but ARM recommends that software uses `FMOV Sd,WZR` or `FMOV Dd,XZR` to provide consistency across a range of microarchitectures.

Table C3-51 shows the Floating-point move (immediate) instruction:

Table C3-51 Floating-point move (immediate) instruction

Mnemonic	Instruction	See
`FMOV`	Floating-point move immediate	*FMOV (scalar, immediate)* on page C7-958

C3.5.4 Floating-point conversion

The following subsections describe the conversion of floating-point values:

- *Convert floating-point precision*.
- *Convert between floating-point and integer or fixed-point*.

Convert floating-point precision

These instructions convert a floating-point scalar with one precision to a floating-point scalar with a different precision, using the current rounding mode as specified by FPCR.RMode.

Table C3-52 shows the Floating-point precision conversion instruction.

Table C3-52 Floating-point precision conversion instruction

Mnemonic	Instruction	See
FCVT	Floating-point convert precision (scalar)	*FCVT* on page C7-861

Convert between floating-point and integer or fixed-point

These instructions convert a floating-point scalar in a SIMD and floating-point register to or from a signed or unsigned integer or fixed-point in a general-purpose register. For a fixed-point value, a final immediate operand indicates that the general-purpose register holds a fixed-point number and `fbits` indicates the number of bits after the binary point. `fbits` is in the range 1- 32 inclusive for a 32-bit general-purpose register name, and 1-64 inclusive for a 64-bit general-purpose register name.

These instructions generate the Invalid Operation exception, in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out-of-range integer or fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input generates an Inexact exception. When flush-to-zero mode is enabled, zero replaces a denormal input and generates an Input Denormal exception.

Table C3-53 shows the Floating-point and fixed-point conversion instructions.

Table C3-53 Floating-point and integer or fixed-point conversion instructions

Mnemonic	Instruction	See
FCVTAS	Floating-point scalar convert to signed integer, rounding to nearest with ties to away (scalar form)	*FCVTAS (scalar)* on page C7-865
FCVTAU	Floating-point scalar convert to unsigned integer, rounding to nearest with ties to away (scalar form)	*FCVTAU (scalar)* on page C7-869
FCVTMS	Floating-point scalar convert to signed integer, rounding toward minus infinity (scalar form)	*FCVTMS (scalar)* on page C7-874.
FCVTMU	Floating-point scalar convert to unsigned integer, rounding toward minus infinity (scalar form)	*FCVTMU (scalar)* on page C7-878
FCVTNS	Floating-point scalar convert to signed integer, rounding to nearest with ties to even (scalar form)	*FCVTNS (scalar)* on page C7-883.
FCVTNU	Floating-point scalar convert to unsigned integer, rounding to nearest with ties to even (scalar form)	*FCVTNU (scalar)* on page C7-887

UCVTF	• Unsigned integer scalar convert to floating-point, using the current rounding mode (scalar form) • Unsigned fixed-point convert to floating-point, using the current rounding mode (scalar form)	• *UCVTF (vector, integer)* on page C7-1318 • *UCVTF (scalar, fixed-point)* on page C7-1320

C3.5.5 Floating-point round to integral

The Floating-point round to integral instructions round a floating-point value to an integral floating-point value of the same size.

These instructions generate the Invalid Operation exception in response to a signaling NaN input, or the Input Denormal exception in response to a denormal input when flush-to-zero mode is enabled. The FRINTX instruction can also generate the Inexact exception if the result is numeric and does not have the same numerical value as the input. A zero input gives a zero result with the same sign, an infinite input gives an infinite result with the same sign, and a NaN is propagated as in normal floating-point arithmetic.

Table C3-54 shows the Floating-point round to integral instructions.

Table C3-54 Floating-point round to integral instructions

Mnemonic	Instruction	See
FRINTA	Floating-point round to integral, to nearest with ties to away	*FRINTA (scalar)* on page C7-984
FRINTI	Floating-point round to integral, using current rounding mode	*FRINTI (scalar)* on page C7-986.
FRINTM	Floating-point round to integral, toward minus infinity	*FRINTM (scalar)* on page C7-988
FRINTN	Floating-point round to integral, to nearest with ties to even	*FRINTN (scalar)* on page C7-990
FRINTP	Floating-point round to integral, toward positive infinity	*FRINTP (scalar)* on page C7-992
FRINTX	Floating-point round to integral exact, using current rounding mode	*FRINTX (scalar)* on page C7-994.
FRINTZ	Floating-point round to integral, toward zero	*FRINTZ (scalar)* on page C7-996

C3.5.6 Floating-point multiply-add

Table C3-55 shows the Floating-point multiply-add instructions that require three source register operands.

Table C3-55 Floating-point multiply-add instructions

Mnemonic	Instruction	See
FMADD	Floating-point scalar fused multiply-add	*FMADD* on page C7-917
FMSUB	Floating-point scalar fused multiply-subtract	*FMSUB* on page C7-959
FNMADD	Floating-point scalar negated fused multiply-add	*FNMADD* on page C7-973
FNMSUB	Floating-point scalar negated fused multiply-subtract	*FNMSUB* on page C7-975

C3.5.7 Floating-point arithmetic (one source)

Table C3-56 shows the Floating-point arithmetic instructions that require a single source register operand.

Table C3-56 Floating-point arithmetic instructions with one source register

Mnemonic	Instructions	See
FABS	Floating-point scalar absolute value	*FABS (scalar)* on page C7-831
FNEG	Floating-point scalar negate	*FNEG (scalar)* on page C7-972
FSQRT	Floating-point scalar square root	*FSQRT (scalar)* on page C7-1002

C3.5.8 Floating-point arithmetic (two sources)

Table C3-57 shows the Floating-point arithmetic instructions that require two source register operands.

Table C3-57 Floating-point arithmetic instructions with two source registers

Mnemonic	Instruction	See
FADD	Floating-point scalar add	*FADD (scalar)* on page C7-837
FDIV	Floating-point scalar divide	*FDIV (scalar)* on page C7-916
FMUL	Floating-point scalar multiply	*FMUL (scalar)* on page C7-965
FNMUL	Floating-point scalar multiply-negate	*FNMUL* on page C7-977
FSUB	Floating-point scalar subtract	*FSUB (scalar)* on page C7-1004

C3.5.9 Floating-point minimum and maximum

The `min(x,y)` and `max(x,y)` operations return a quiet NaN when either *x* or *y* is NaN. In flush-to-zero mode subnormal operands are flushed to zero before comparison, and if the result of the comparison is the flushed value, then a zero value is returned. Where both *x* and *y* are zero, or subnormal values flushed to zero, with different signs, then +0.0 is returned by `max()` and -0.0 by `min()`.

The `minNum(x,y)` and `maxNum(x,y)` operations follow the IEEE 754-2008 standard and return the numerical operand when one operand is numerical and the other a quiet NaN. Apart from this additional handling of a single quiet NaN the result is then identical to `min(x,y)` and `max(x,y)`.

Table C3-58 shows the Floating-point instructions that can perform floating-point minimum and maximum operations.

Table C3-58 Floating-point minimum and maximum instructions

Mnemonic	Instruction	See
FMAX	Floating-point scalar maximum	*FMAX (scalar)* on page C7-921.
FMAXNM	Floating-point scalar maximum number	*FMAXNM (scalar)* on page C7-924
FMIN	Floating-point scalar minimum	*FMIN (scalar)* on page C7-935
FMINNM	Floating-point scalar minimum number	*FMINNM (scalar)* on page C7-938

C3.5.10 Floating-point comparison

These instructions set the NZCV condition flags in PSTATE, based on the result of a comparison of two operands. If the floating-point comparisons are *unordered*, where one or both operands are a form of NaN, the C and V bits are set to 1 and the N and Z bits are cleared to 0.

Note

The NZCV flags in the FPSR are associated with AArch32 state. The A64 floating-point comparison instructions do not change the condition flags in the FPSR.

For the conditional Floating-point comparison instructions, if the condition is TRUE, the flags are updated to the result of the comparison, otherwise the flags are updated to the immediate value that is defined in the instruction encoding.

The quiet compare instructions generate an Invalid Operation exception if either of the source operands is a signaling NaN. The signaling compare instructions generate an Invalid Operation exception if either of the source operands is any type of NaN.

Table C3-59 shows the Floating-point comparison instructions.

Table C3-59 Floating-point comparison instructions

Mnemonic	Instruction	See
FCMP	Floating-point quiet compare	*FCMP* on page C7-858.
FCMPE	Floating-point signaling compare	*FCMPE* on page C7-859.
FCCMP	Floating-point conditional quiet compare	*FCCMP* on page C7-840
FCCMPE	Floating-point conditional signaling compare	*FCCMPE* on page C7-841.

C3.5.11 Floating-point conditional select

Table C3-60 shows the Floating-point conditional select instructions.

Table C3-60 Floating-point conditional select instructions

Mnemonic	Instruction	See
FCSEL	Floating-point scalar conditional select	*FCSEL* on page C7-860

C3.5.12 SIMD move

The functionality of some data movement instructions overlaps with that provided by the scalar floating-point FMOV instructions described in *Floating-point move (register)* on page C3-155.

Table C3-61 shows the SIMD move instructions.

Table C3-61 SIMD move instructions

Mnemonic	Instruction	See
DUP	• Duplicate vector element to vector or scalar • Duplicate general-purpose register to vector	• *DUP (element)* on page C7-821 • *DUP (general)* on page C7-823
INS	• Insert vector element from another vector element • Insert vector element from general-purpose register **Note** Normally disassembled as MOV.	• *INS (element)* on page C7-1005 • *INS (general)* on page C7-1007

C3.5.14 SIMD compare

The SIMD compare instructions compare vector or scalar elements according to the specified condition and set the destination vector element to all ones if the condition holds, or to zero if the condition does not hold.

Note

Some of the comparisons, such as LS, LE, LO, and LT, can be made by reversing the operands and using the opposite comparison, HS, GE, HI, or GT.

Table C3-63 shows that SIMD compare instructions.

Table C3-63 SIMD compare instructions

Mnemonic	Instruction	See
CMEQ	• Compare bitwise equal (vector and scalar form) • Compare bitwise equal to zero (vector and scalar form)	• *CMEQ (register)* on page C7-798 • *CMEQ (zero)* on page C7-800
CMHS	Compare unsigned higher or same (vector and scalar form)	*CMHS (register)* on page C7-812
CMGE	• Compare signed greater than or equal (vector and scalar form) • Compare signed greater than or equal to zero (vector and scalar form)	• *CMGE (register)* on page C7-802 • *CMGE (zero)* on page C7-804
CMHI	Compare unsigned higher (vector and scalar form)	*CMHI (register)* on page C7-810
CMGT	• Compare signed greater than (vector and scalar form) • Compare signed greater than zero (vector and scalar form)	• *CMGT (register)* on page C7-806 • *CMGT (zero)* on page C7-808

Mnemonic	Instruction	See
CMLE	Compare signed less than or equal to zero (vector and scalar form)	*CMLE (zero)* on page C7-814
CMLT	Compare signed less than zero (vector and scalar form)	*CMLT (zero)* on page C7-816
CMTST	Compare bitwise test bits nonzero (vector and scalar form)	*CMTST* on page C7-818
FCMEQ	• Floating-point compare equal (vector and scalar form) • Floating-point compare equal to zero (vector and scalar form)	• *FCMEQ (register)* on page C7-842 • *FCMEQ (zero)* on page C7-844
FCMGE	• Floating-point compare greater than or equal (vector and scalar form) • Floating-point compare greater than or equal to zero (vector and scalar form)	• *FCMGE (register)* on page C7-846 • *FCMGE (zero)* on page C7-848
FCMGT	• Floating-point compare greater than (vector and scalar form) • Floating-point compare greater than zero (vector and scalar form)	• *FCMGT (register)* on page C7-850 • *FCMGT (zero)* on page C7-852
FCMLE	Floating-point compare less than or equal to zero (vector and scalar form)	*FCMLE (zero)* on page C7-854
FCMLT	Floating-point compare less than zero (vector and scalar form)	*FCMLT (zero)* on page C7-856
FACGE	Floating-point absolute compare greater than or equal (vector and scalar form)	*FACGE* on page C7-832
FACGT	Floating-point absolute compare greater than (vector and scalar form)	*FACGT* on page C7-834

C3.5.15 SIMD widening and narrowing arithmetic

For information about the variants of these instructions, see *Common features of SIMD instructions* on page C3-154.

Table C3-64 shows the SIMD widening and narrowing arithmetic instructions.

Table C3-64 SIMD widening and narrowing arithmetic instructions

Mnemonic	Instruction	See
ADDHN, ADDHN2	Add returning high, narrow (vector form)	*ADDHN, ADDHN2* on page C7-777
PMULL, PMULL2	Polynomial multiply long (vector form)	*PMULL, PMULL2* on page C7-1089 See also *The Cryptographic Extensions* on page C3-171
RADDHN, RADDHN2	Rounding add returning high, narrow (vector form)	*RADDHN, RADDHN2* on page C7-1091
RSUBHN, RSUBHN2	Rounding subtract returning high, narrow (vector form)	*RSUBHN, RSUBHN2* on page C7-1102
SABAL, SABAL2	Signed absolute difference and accumulate long (vector form)	*SABAL, SABAL2* on page C7-1105
SABDL, SABDL2	Signed absolute difference long (vector form)	*SABDL, SABDL2* on page C7-1108
SADDL, SADDL2	Signed add long (vector form)	*SADDL, SADDL2* on page C7-1112
SADDW, SADDW2	Signed add wide (vector form)	*SADDW, SADDW2* on page C7-1117
SMLAL, SMLAL2	Signed multiply-add long (vector form)	*SMLAL, SMLAL2 (vector)* on page C7-1157

Table C3-64 SIMD widening and narrowing arithmetic instructions (continued)

Mnemonic	Instruction	See
SMLSL, SMLSL2	Signed multiply-subtract long (vector form)	*SMLSL, SMLSL2 (vector)* on page C7-1161
SMULL, SMULL2	Signed multiply long (vector form)	*SMULL, SMULL2 (vector)* on page C7-1167
SQDMLAL, SQDMLAL2	Signed saturating doubling multiply-add long (vector and scalar form)	*SQDMLAL, SQDMLAL2 (vector)* on page C7-1176
SQDMLSL, SQDMLSL2	Signed saturating doubling multiply-subtract long (vector and scalar form)	*SQDMLSL, SQDMLSL2 (vector)* on page C7-1182
SQDMULL, SQDMULL2	Signed saturating doubling multiply long (vector and scalar form)	*SQDMULL, SQDMULL2 (vector)* on page C7-1193
SSUBL, SSUBL2	Signed subtract long (vector form)	*SSUBL, SSUBL2* on page C7-1247
SSUBW, SSUBW2	Signed subtract wide (vector form)	*SSUBW, SSUBW2* on page C7-1249
SUBHN, SUBHN2	Subtract returning high, narrow (vector form)	*SUBHN, SUBHN2* on page C7-1290
UABAL, UABAL2	Unsigned absolute difference and accumulate long (vector form)	*UABAL, UABAL2* on page C7-1302
UABDL, UABDL2	Unsigned absolute difference long (vector form)	*UABDL, UABDL2* on page C7-1305
UADDL, UADDL2	Unsigned add long (vector form)	*UADDL, UADDL2* on page C7-1309
UADDW, UADDW2	Unsigned add wide (vector form)	*UADDW, UADDW2* on page C7-1314
UMLAL, UMLAL2	Unsigned multiply-add long (vector form)	*UMLAL, UMLAL2 (vector)* on page C7-1336
UMLSL, UMLSL2	Unsigned multiply-subtract long (vector form)	*UMLSL, UMLSL2 (vector)* on page C7-1340
UMULL, UMULL2	Unsigned multiply long (vector form)	*UMULL, UMULL2 (vector)* on page C7-1346
USUBL, USUBL2	Unsigned subtract long (vector form)	*USUBL, USUBL2* on page C7-1386
USUBW, USUBW2	Unsigned subtract wide (vector form)	*USUBW, USUBW2* on page C7-1388

C3.5.16 SIMD unary arithmetic

For information about the variants of these instructions, see *Common features of SIMD instructions* on page C3-154.

Table C3-65 shows the SIMD unary arithmetic instructions.

Table C3-65 SIMD unary arithmetic instructions

Mnemonic	Instruction	See
ABS	Absolute value (vector and scalar form)	*ABS* on page C7-773
CLS	Count leading sign bits (vector form)	*CLS (vector)* on page C7-796
CLZ	Count leading zero bits (vector form)	*CLZ (vector)* on page C7-797
CNT	Population count per byte (vector form)	*CNT* on page C7-820
FABS	Floating-point absolute (vector form)	*FABS (vector)* on page C7-830
FCVTL, FCVTL2	Floating-point convert to higher precision long (vector form)	*FCVTL, FCVTL2* on page C7-871
FCVTN, FCVTN2	Floating-point convert to lower precision narrow (vector form)	*FCVTN, FCVTN2* on page C7-880

Table C3-65 SIMD unary arithmetic instructions (continued)

Mnemonic	Instruction	See
FCVTXN, FCVTXN2	Floating-point convert to lower precision narrow, rounding to odd (vector and scalar form)	*FCVTXN, FCVTXN2* on page C7-897
FNEG	Floating-point negate (vector form)	*FNEG (vector)* on page C7-971
FRECPE	Floating-point reciprocal estimate (vector and scalar form)	*FRECPE* on page C7-978
FRECPX	Floating-point reciprocal square root (scalar form)	*FRECPX* on page C7-982
FRINTA	Floating-point round to integral, to nearest with ties to away (vector form)	*FRINTA (scalar)* on page C7-984
FRINTI	Floating-point round to integral, using current rounding mode (vector form)	*FRINTI (vector)* on page C7-985
FRINTM	Floating-point round to integral, toward minus infinity (vector form)	*FRINTM (vector)* on page C7-987
FRINTN	Floating-point round to integral, to nearest with ties to even (vector form)	*FRINTN (vector)* on page C7-989
FRINTP	Floating-point round to integral, toward positive infinity (vector form)	*FRINTP (vector)* on page C7-991
FRINTX	Floating-point round to integral exact, using current rounding mode (vector form)	*FRINTX (vector)* on page C7-993
FRINTZ	Floating-point round to integral, toward zero (vector form)	*FRINTZ (vector)* on page C7-995
FRSQRTE	Floating-point reciprocal square root estimate (vector and scalar form)	*FRSQRTE* on page C7-997
FSQRT	Floating-point square root (vector form)	*FSQRT (vector)* on page C7-1001
MVN	Bitwise NOT (vector form)	*MVN* on page C7-1078
NEG	Negate (vector and scalar form)	*NEG (vector)* on page C7-1081
NOT	Bitwise NOT (vector form)	*NOT* on page C7-1083
RBIT	Bitwise reverse (vector form)	*RBIT (vector)* on page C7-1093
REV16	Reverse elements in 16-bit halfwords (vector form)	*REV16 (vector)* on page C7-1094
REV32	Reverse elements in 32-bit words (vector form)	*REV32 (vector)* on page C7-1096
REV64	Reverse elements in 64-bit doublewords (vector form)	*REV64* on page C7-1098
SADALP	Signed add and accumulate long pairwise (vector form)	*SADALP* on page C7-1110
SADDLP	Signed add long pairwise (vector form)	*SADDLP* on page C7-1114
SQABS	Signed saturating absolute value (vector and scalar form)	*SQABS* on page C7-1169
SQNEG	Signed saturating negate (vector and scalar form)	*SQNEG* on page C7-1195
SQXTN, SQXTN2	Signed saturating extract narrow (vector form)	*SQXTN, SQXTN2* on page C7-1226
SQXTUN, SQXTUN2	Signed saturating extract unsigned narrow (vector and scalar form)	*SQXTUN, SQXTUN2* on page C7-1228
SUQADD	Signed saturating accumulate of unsigned value (vector and scalar form)	*SUQADD* on page C7-1292

Table C3-65 SIMD unary arithmetic instructions (continued)

Mnemonic	Instruction	See
SXTL, SXTL2	Signed extend long	*SXTL* on page C7-1294
UADALP	Unsigned add and accumulate long pairwise (vector form)	*UADALP* on page C7-1307
UADDLP	Unsigned add long pairwise (vector form)	*UADDLP* on page C7-1311
UQXTN, UQXTN2	Unsigned saturating extract narrow (vector form)	*UQXTN, UQXTN2* on page C7-1365
URECPE	Unsigned reciprocal estimate (vector form)	*URECPE* on page C7-1367
URSQRTE	Unsigned reciprocal square root estimate (vector form)	*URSQRTE* on page C7-1373
USQADD	Unsigned saturating accumulate of signed value (vector and scalar form)	*USQADD* on page C7-1382
UXTL, UXTL2	Unsigned extend long	*UXTL* on page C7-1390
XTN, XTN2	Extract narrow (vector form)	*XTN, XTN2* on page C7-1393

C3.5.17 SIMD by element arithmetic

For information about the variants of these instructions, see *Common features of SIMD instructions* on page C3-154.

Table C3-66 shows the SIMD by element arithmetic instructions.

Table C3-66 SIMD by element arithmetic instructions

Mnemonic	Instruction	See
FMLA	Floating-point fused multiply-add (vector and scalar form)	*FMLA (by element)* on page C7-947
FMLS	Floating-point fused multiply-subtract (vector and scalar form)	*FMLS (by element)* on page C7-950.
FMUL	Floating-point multiply (vector and scalar form)	*FMUL (by element)* on page C7-961
FMULX	Floating-point multiply extended (vector and scalar form)	*FMULX (by element)* on page C7-966
MLA	Multiply-add (vector form)	*MLA (by element)* on page C7-1059
MLS	Multiply-subtract (vector form)	*MLS (by element)* on page C7-1063
MUL	Multiply (vector form)	*MUL (by element)* on page C7-1074
SMLAL, SMLAL2	Signed multiply-add long (vector form)	*SMLAL, SMLAL2 (by element)* on page C7-1155
SMLSL, SMLSL2	Signed multiply-subtract long (vector form)	*SMLSL, SMLSL2 (by element)* on page C7-1159
SMULL, SMULL2	Signed multiply long (vector form)	*SMULL, SMULL2 (by element)* on page C7-1165
SQDMLAL, SQDMLAL2	Signed saturating doubling multiply-add long (vector and scalar form)	*SQDMLAL, SQDMLAL2 (by element)* on page C7-1173
SQDMLSL, SQDMLSL2	Signed saturating doubling multiply-subtract long (vector form)	*SQDMLSL, SQDMLSL2 (by element)* on page C7-1179
SQDMULH	Signed saturating doubling multiply returning high half (vector and scalar form)	*SQDMULH (by element)* on page C7-1185

Table C3-66 SIMD by element arithmetic instructions (continued)

Mnemonic	Instruction	See
SQDMULL, SQDMULL2	Signed saturating doubling multiply long (vector and scalar form)	*SQDMULL, SQDMULL2 (by element)* on page C7-1190
SQRDMULH	Signed saturating rounding doubling multiply returning high half (vector and scalar form)	*SQRDMULH (by element)* on page C7-1197
UMLAL, UMLAL2	Unsigned multiply-add long (vector form)	*UMLAL, UMLAL2 (by element)* on page C7-1334
UMLSL, UMLSL2	Unsigned multiply-subtract long (vector form)	*UMLSL, UMLSL2 (by element)* on page C7-1338
UMULL, UMULL2	Unsigned multiply long (vector form)	*UMULL, UMULL2 (by element)* on page C7-1344

C3.5.18 SIMD permute

Table C3-67 shows the SIMD permute instructions.

Table C3-67 SIMD permute instructions

Mnemonic	Instruction	See
EXT	Extract vector from a pair of vectors	*EXT* on page C7-827
TRN1	Transpose vectors (primary)	*TRN1* on page C7-1299
TRN2	Transpose vectors (secondary)	*TRN2* on page C7-1300
UZP1	Unzip vectors (primary)	*UZP1* on page C7-1391
UZP2	Unzip vectors (secondary)	*UZP2* on page C7-1392
ZIP1	Zip vectors (primary)	*ZIP1* on page C7-1395
ZIP2	Zip vectors (secondary)	*ZIP2* on page C7-1396

C3.5.19 SIMD immediate

Table C3-68 shows the SIMD immediate instructions.

Table C3-68 SIMD immediate instructions

Mnemonic	Instruction	See
BIC	Bitwise bit clear immediate	*BIC (vector, immediate)* on page C7-787
FMOV	Floating-point move immediate	*FMOV (vector, immediate)* on page C7-953
MOVI	Move immediate	*MOVI* on page C7-1072
MVNI	Move inverted immediate	*MVNI* on page C7-1079
ORR	Bitwise inclusive OR immediate	*ORR (vector, immediate)* on page C7-1085

C3.5.20 SIMD shift (immediate)

For information about the variants of these instructions, see *Common features of SIMD instructions* on page C3-154.

Table C3-69 shows the SIMD shift immediate instructions.

Table C3-69 SIMD shift (immediate) instructions

Mnemonic	Instruction	See
RSHRN, RSHRN2	Rounding shift right narrow immediate (vector form)	*RSHRN, RSHRN2* on page C7-1100
SHL	Shift left immediate (vector and scalar form)	*SHL* on page C7-1138
SHLL, SHLL2	Shift left long (by element size) (vector form)	*SHLL, SHLL2* on page C7-1140
SHRN, SHRN2	Shift right narrow immediate (vector form)	*SHRN, SHRN2* on page C7-1142
SLI	Shift left and insert immediate (vector and scalar form)	*SLI* on page C7-1145
SQRSHRN, SQRSHRN2	Signed saturating rounded shift right narrow immediate (vector and scalar form)	*SQRSHRN, SQRSHRN2* on page C7-1204
SQRSHRUN, SQRSHRUN2	Signed saturating shift right unsigned narrow immediate (vector and scalar form)	*SQRSHRUN, SQRSHRUN2* on page C7-1207
SQSHL	Signed saturating shift left immediate (vector and scalar form)	*SQSHL (immediate)* on page C7-1210
SQSHLU	Signed saturating shift left unsigned immediate (vector and scalar form)	*SQSHLU* on page C7-1215
SQSHRN, SQSHRN2	Signed saturating shift right narrow immediate (vector and scalar form)	*SQSHRN, SQSHRN2* on page C7-1218
SQSHRUN, SQSHRUN2	Signed saturating shift right unsigned narrow immediate (vector and scalar form)	*SQSHRUN, SQSHRUN2* on page C7-1221
SRI	Shift right and insert immediate (vector and scalar form)	*SRI* on page C7-1231
SRSHR	Signed rounding shift right immediate (vector and scalar form)	*SRSHR* on page C7-1235
SRSRA	Signed rounding shift right and accumulate immediate (vector and scalar form)	*SRSRA* on page C7-1237.
SSHLL, SSHLL2	Signed shift left long immediate (vector form)	*SSHLL, SSHLL2* on page C7-1241
SSHR	Signed shift right immediate (vector and scalar form)	*SSHR* on page C7-1243
SSRA	Signed integer shift right and accumulate immediate (vector and scalar form)	*SSRA* on page C7-1245
SXTL, SXTL2	Signed integer extend (vector only)	*SXTL* on page C7-1294
UQRSHRN, UQRSHRN2	Unsigned saturating rounded shift right narrow immediate (vector and scalar form)	*UQRSHRN, UQRSHRN2* on page C7-1352
UQSHL	Unsigned saturating shift left immediate (vector and scalar form)	*UQSHL (immediate)* on page C7-1355
UQSHRN, UQSHRN2	Unsigned saturating shift right narrow immediate (vector and scalar form)	*UQSHRN* on page C7-1360
URSHR	Unsigned rounding shift right immediate (vector and scalar form)	*URSHR* on page C7-1371
URSRA	Unsigned integer rounding shift right and accumulate immediate (vector and scalar form)	*URSRA* on page C7-1374
USHLL, USHLL2	Unsigned shift left long immediate (vector form)	*USHLL, USHLL2* on page C7-1378

Table C3-69 SIMD shift (immediate) instructions (continued)

Mnemonic	Instruction	See
USHR	Unsigned shift right immediate (vector and scalar form)	*USHR* on page C7-1380
USRA	Unsigned shift right and accumulate immediate (vector and scalar form)	*USRA* on page C7-1384
UXTL, UXTL2	Unsigned integer extend (vector only)	*UXTL* on page C7-1390

C3.5.21 SIMD floating-point and integer conversion

The SIMD floating-point and integer conversion instructions generate the Invalid Operation exception in response to a floating-point input of NaN, infinity, or a numerical value that cannot be represented within the destination register. An out-of-range integer or a fixed-point result is saturated to the size of the destination register. A numeric result that differs from the input raises the Inexact exception.

Table C3-70 shows the SIMD floating-point and integer conversion instructions.

Table C3-70 SIMD floating-point and integer conversion instructions

Mnemonic	Instruction	See
FCVTAS	Floating-point convert to signed integer, rounding to nearest with ties to away (vector and scalar form)	*FCVTAS (vector)* on page C7-863
FCVTAU	Floating-point convert to unsigned integer, rounding to nearest with ties to away (vector and scalar form)	*FCVTAU (vector)* on page C7-867
FCVTMS	Floating-point convert to signed integer, rounding toward minus infinity (vector and scalar form)	*FCVTMS (vector)* on page C7-872
FCVTMU	Floating-point convert to unsigned integer, rounding toward minus infinity (vector and scalar form)	*FCVTMU (vector)* on page C7-876
FCVTNS	Floating-point convert to signed integer, rounding to nearest with ties to even (vector and scalar form)	*FCVTNS (vector)* on page C7-881
FCVTNU	Floating-point convert to unsigned integer, rounding to nearest with ties to even (vector and scalar form)	*FCVTNU (vector)* on page C7-885
FCVTPS	Floating-point convert to signed integer, rounding toward positive infinity (vector and scalar form)	*FCVTPS (vector)* on page C7-889
FCVTPU	Floating-point convert to unsigned integer, rounding toward positive infinity (vector and scalar form)	*FCVTPU (vector)* on page C7-893
FCVTZS	• Floating-point convert to signed integer, rounding toward zero (vector and scalar form) • Floating-point convert to signed fixed-point, rounding toward zero (vector and scalar form)	• *FCVTZS (vector, integer)* on page C7-901 • *FCVTZS (vector, fixed-point)* on page C7-899

Table C3-70 SIMD floating-point and integer conversion instructions (continued)

Mnemonic	Instruction	See
FCVTZU	• Floating-point convert to unsigned integer, rounding toward zero (vector and scalar form) • Floating-point convert to unsigned fixed-point, rounding toward zero, (vector and scalar form)	• *FCVTZU (vector, integer)* on page C7-909 • *FCVTZU (vector, fixed-point)* on page C7-907
SCVTF	• Signed integer convert to floating-point (vector and scalar form) • Signed fixed-point convert to floating-point (vector and scalar form)	• *SCVTF (vector, integer)* on page C7-1121 • *SCVTF (vector, fixed-point)* on page C7-1119
UCVTF	• Unsigned integer convert to floating-point (vector and scalar form) • Unsigned fixed-point convert to floating-point (vector and scalar form)	• *UCVTF (vector, integer)* on page C7-1318 • *UCVTF (vector, fixed-point)* on page C7-1316

C3.5.22 SIMD reduce (across vector lanes)

The SIMD reduce (across vector lanes) instructions perform arithmetic operations horizontally, that is across all lanes of the input vector. They deliver a single scalar result.

Table C3-71 shows the SIMD reduce (across vector lanes) instructions.

Table C3-71 SIMD reduce (across vector lanes) instructions

Mnemonic	Instruction	See
ADDV	Add (across vector)	*ADDV* on page C7-781
FMAXNMV	Floating-point maximum number (across vector)	*FMAXNMV* on page C7-928
FMAXV	Floating-point maximum (across vector)	*FMAXV* on page C7-932
FMINNMV	Floating-point minimum number (across vector)	*FMINNMV* on page C7-942
FMINV	Floating-point minimum (across vector)	*FMINV* on page C7-946
SADDLV	Signed add long (across vector)	*SADDLV* on page C7-1116
SMAXV	Signed maximum (across vector)	*SMAXV* on page C7-1149
SMINV	Signed minimum (across vector)	*SMINV* on page C7-1153
UADDLV	Unsigned add long (across vector)	*UADDLV* on page C7-1313
UMAXV	Unsigned maximum (across vector)	*UMAXV* on page C7-1328
UMINV	Unsigned minimum (across vector)	*UMINV* on page C7-1332

C3.5.23 SIMD pairwise arithmetic

The SIMD pairwise arithmetic instructions perform operations on pairs of adjacent elements and deliver a vector result.

Table C3-72 shows the SIMD pairwise arithmetic instructions.

Table C3-72 SIMD pairwise arithmetic instructions

Mnemonic	Instruction	See
ADDP	Add pairwise (vector and scalar form)	• *ADDP (vector)* on page C7-780 • *ADDP (scalar)* on page C7-779
FADDP	Floating-point add pairwise (vector and scalar form)	• *FADDP (vector)* on page C7-839 • *FADDP (scalar)* on page C7-838
FMAXNMP	Floating-point maximum number pairwise (vector and scalar form)	• *FMAXNMP (vector)* on page C7-926 • *FMAXNMP (scalar)* on page C7-925
FMAXP	Floating-point maximum pairwise (vector and scalar form)	• *FMAXP (vector)* on page C7-930 • *FMAXP (scalar)* on page C7-929
FMINNMP	Floating-point minimum number pairwise (vector and scalar form)	• *FMINNMP (vector)* on page C7-940 • *FMINNMP (scalar)* on page C7-939
FMINP	Floating-point minimum pairwise (vector and scalar form)	• *FMINP (vector)* on page C7-944 • *FMINP (scalar)* on page C7-943
SMAXP	Signed maximum pairwise	*SMAXP* on page C7-1148
SMINP	Signed minimum pairwise	*SMINP* on page C7-1152
UMAXP	Unsigned maximum pairwise	*UMAXP* on page C7-1327
UMINP	Unsigned minimum pairwise	*UMINP* on page C7-1331

C3.5.24 SIMD table lookup

Table C3-73 shows the SIMD table lookup instructions.

Table C3-73 SIMD table lookup instructions

Mnemonic	Instruction	See
TBL	Table vector lookup	*TBL* on page C7-1295
TBX	Table vector lookup extension	*TBX* on page C7-1297

C3.5.25 The Cryptographic Extensions

The instructions provided by the optional Cryptographic Extension share the SIMD and floating-point register file. For more information see:

- *Announcing the Advanced Encryption Standard.*
- *The Galois/Counter Mode of Operation.*
- *Announcing the Secure Hash Standard.*

Table C3-74 shows the Cryptographic Extension instructions.

Table C3-74 Cryptographic Extension instructions

Mnemonic	Instruction	See
AESD	AES single round decryption	*AESD* on page C7-782
AESE	AES single round encryption	*AESE* on page C7-783
AESIMC	AES inverse mix columns	*AESIMC* on page C7-784
AESMC	AES mix columns	*AESMC* on page C7-785
PMULL	Polynomial multiply long	*PMULL, PMULL2* on page C7-1089
SHA1C	SHA1 hash update (choose)	*SHA1C* on page C7-1127
SHA1H	SHA1 fixed rotate	*SHA1H* on page C7-1128
SHA1M	SHA1 hash update (majority)	*SHA1M* on page C7-1129
SHA1P	SHA1 hash update (parity)	*SHA1P* on page C7-1130
SHA1SU0	SHA1 schedule update 0	*SHA1SU0* on page C7-1131
SHA1SU1	SHA1 schedule update 1	*SHA1SU1* on page C7-1132
SHA256H	SHA256 hash update (part 1)	*SHA256H* on page C7-1134
SHA256H2	SHA256 hash update (part 2)	*SHA256H2* on page C7-1133
SHA256SU0	SHA256 schedule update 0	*SHA256SU0* on page C7-1135
SHA256SU1	SHA256 schedule update 1	*SHA256SU1* on page C7-1136

Chapter C4
A64 Instruction Set Encoding

This chapter describes the A64 instruction set encoding. It contains an encoding index followed by a set of functional groups. Each group contains an alphabetical list of instructions that have similar function within the instruction set.

It contains the following sections:

C4.1 A64 instruction index by encoding

Table C4-1 A64 main encoding table

Instruction bits																						Encoding Group
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	
-	-	-	0	0	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	-	UNALLOCATED

C4.2 Branches, exception generating and system instructions

This section describes the encoding of the instruction classes in the Branch, exception generation and system instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see *Branches, Exception generating, and System instructions* on page C3-126.

Table C4-2 Encoding table for the Branches, Exception Generating and System instructions functional group

Instruction bits																						Instruction class
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10

C4.4 Data processing - immediate

This section describes the encoding of the instruction classes in the Data processing (immediate) instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see *Data processing - immediate* on page C3-142.

Table C4-4 Encoding table for the Data Processing - Immediate functional group

Instruction bits																				Instruction class
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11 10

C4.6 Data processing - SIMD and floating point

This section describes the encoding of the instruction classes in the Data processing (SIMD and floating-point) instruction group, and shows how each instruction class encodes the different instruction forms. For additional information on this functional group of instructions, see *Data processing - SIMD and floating-point* on page C3-154.

Table C4-6 Encoding table for the Data Processing - Scalar Floating-Point and Advanced SIMD functional group

Instruction bits																						Instruction class
31	30	29	28	27	26	25	24	23	22	21	20	19	18	17	16	15	14	13	12	11	10	
-	0	-	1	1	1	1	0	-	-	0	-	-	-	-	-	-	-	-	-	-	-	Floating-point<->fixed-point conversions
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	-	0	1	Floating-point conditional compare
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	-	1	0	Floating-point data-processing (2 source)
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	-	1	1	Floating-point conditional select
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	1	0	0	Floating-point immediate
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	-	1	0	0	0	Floating-point compare
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	-	1	0	0	0	0	Floating-point data-processing (1 source)
-	0	-	1	1	1	1	0	-	-	1	-	-	-	-	-	0	0	0	0	0	0	Floating-point<->integer conversions
-	0	-	1	1	1	1	1	-	-	-	-	-	-	-	-	-	-	-	-	-	-	Floating-point data-processing (3 source)
0	-	-	0	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	-	-	1	Advanced SIMD three same
0	-	-	0	1	1	1	0	-	-	1	-	-	-	-	-	-	-	-	-	0	0	Advanced SIMD three different

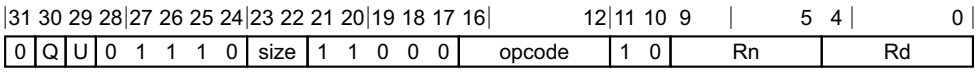
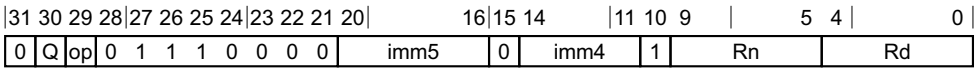
0	1	0	1	1	1	1	0	-	-	0	-	-	-	-	-	0	-	-	-	0	0	Cryptographic three-register SHA
0	1	0	1	1	1	1	0	-	-	1	0	1	0	0	-	-	-	-	-	1	0	Cryptographic two-register SHA

C4.6.1 Advanced SIMD across lanes



Decode fields			Instruction Page	Variant
U	size	opcode		
0	-	00011	SADDLV	-
0	-	01010	SMAXV	-
0	-	11010	SMINV	-
0	-	11011	ADDV	-
1	-	00011	UADDLV	-
1	-	01010	UMAXV	-
1	-	11010	UMINV	-
1	0x	01100	FMAXNMV	-
1	0x	01111	FMAXV	-
1	1x	01100	FMINNMV	-
1	1x	01111	FMINV	-

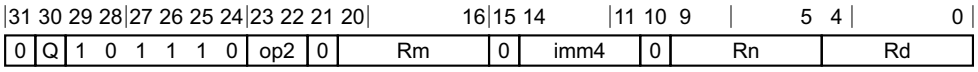
C4.6.2 Advanced SIMD copy



Decode fields				Instruction Page	Variant
Q	op	imm5	imm4		
-	0	-	0000	DUP (element)	Vector
-	0	-	0001	DUP (general)	-
0	0	-	0101	SMOV	32-bit

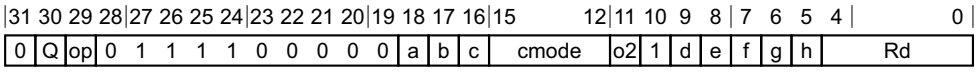
Decode fields				Instruction Page	Variant
Q	op	imm5	imm4		
0	0	-	0111	UMOV	32-bit
1	0	-	0011	INS (general)	-
1	0	-	0101	SMOV	64-bit
1	0	-	0111	UMOV	64-bit
1	1	-	-	INS (element)	-

C4.6.3 Advanced SIMD extract



Decode fields	Instruction Page	Variant
op2		
00	EXT	-

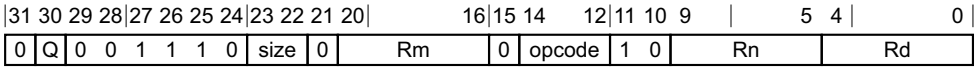
C4.6.4 Advanced SIMD modified immediate



Decode fields				Instruction Page	Variant
Q	op	cmode	o2		
-	0	0xx0	0	MOVI	32-bit shifted immediate
-	0	0xx1	0	ORR (vector, immediate)	32-bit
-	0	10x0	0	MOVI	16-bit shifted immediate
-	0	10x1	0	ORR (vector, immediate)	16-bit
-	0	110x	0	MOVI	32-bit shifting ones
-	0	1110	0	MOVI	8-bit
-	0	1111	0	FMOV (vector, immediate)	Single-precision
-	1	0xx0	0	MVNI	32-bit shifted immediate
-	1	0xx1	0	BIC (vector, immediate)	32-bit
-	1	10x0	0	MVNI	16-bit shifted immediate
-	1	10x1	0	BIC (vector, immediate)	16-bit

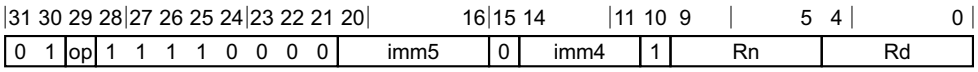
Decode fields				Instruction Page	Variant
Q	op	cmode	o2		
-	1	110x	0	MVNI	32-bit shifting ones
0	1	1110	0	MOVI	64-bit scalar
1	1	1110	0	MOVI	64-bit vector
1	1	1111	0	FMOV (vector, immediate)	Double-precision

C4.6.5 Advanced SIMD permute



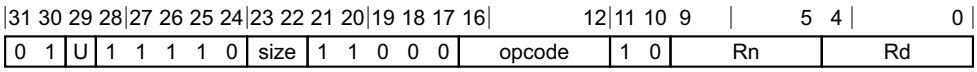
Decode fields	Instruction Page	Variant
opcode		
001	UZP1	-
010	TRN1	-
011	ZIP1	-
101	UZP2	-
110	TRN2	-
111	ZIP2	-

C4.6.6 Advanced SIMD scalar copy



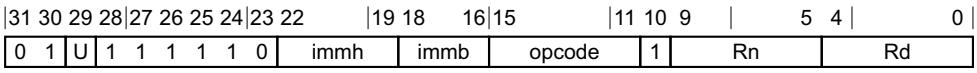
Decode fields			Instruction Page	Variant
op	imm5	imm4		
0	-	0000	DUP (element)	Scalar

C4.6.7 Advanced SIMD scalar pairwise



Decode fields			Instruction Page	Variant
U	size	opcode		
0	-	11011	ADDP (scalar)	-
1	0x	01100	FMAXNMP (scalar)	-
1	0x	01101	FADDP (scalar)	-
1	0x	01111	FMAXP (scalar)	-
1	1x	01100	FMINNMP (scalar)	-
1	1x	01111	FMINP (scalar)	-

C4.6.8 Advanced SIMD scalar shift by immediate



Decode fields			Instruction Page	Variant
U	immh	opcode		
0	!= 0000	00000	SSHR	Scalar
0	!= 0000	00010	SSRA	Scalar

1	0	00	10	000	FCVTMS (scalar)	Single-precision to 64-bit
1	0	00	10	001	FCVTMU (scalar)	Single-precision to 64-bit

Decode fields					Instruction Page	Variant
sf	S	type	rmode	opcode		
1	0	00	11	000	FCVTZS (scalar, integer)	Single-precision to 64-bit
1	0	00	11	001	FCVTZU (scalar, integer)	Single-precision to 64-bit
1	0	01	00	000	FCVTNS (scalar)	Double-precision to 64-bit
1	0	01	00	001	FCVTNU (scalar)	Double-precision to 64-bit
1	0	01	00	010	SCVTF (scalar, integer)	64-bit to double-precision
1	0	01	00	011	UCVTF (scalar, integer)	64-bit to double-precision
1	0	01	00	100	FCVTAS (scalar)	Double-precision to 64-bit
1	0	01	00	101	FCVTAU (scalar)	Double-precision to 64-bit
1	0	01	00	110	FMOV (general)	Double-precision to 64-bit
1	0	01	00	111	FMOV (general)	64-bit to double-precision
1	0	01	01	000	FCVTPS (scalar)	Double-precision to 64-bit
1	0	01	01	001	FCVTPU (scalar)	Double-precision to 64-bit
1	0	01	10	000	FCVTMS (scalar)	Double-precision to 64-bit
1	0	01	10	001	FCVTMU (scalar)	Double-precision to 64-bit
1	0	01	11	000	FCVTZS (scalar, integer)	Double-precision to 64-bit
1	0	01	11	001	FCVTZU (scalar, integer)	Double-precision to 64-bit
1	0	10	01	110	FMOV (general)	Top half of 128-bit to 64-bit
1	0	10	01	111	FMOV (general)	64-bit to top half of 128-bit

Chapter C5
The A64 System Instruction Class

This chapter describes the A64 system instructions and registers, and the system instruction class encoding space. It contains the following sections:

C5.1 About the System instruction and System register descriptions

This section provides general information about the System instructions and the System register descriptions.

The terms defined in *Fixed values in instruction and register descriptions* apply throughout this manual. That is, they are not restricted to the System instruction and the System register descriptions.

C5.1.1 Fixed values in instruction and register descriptions

This section summarizes the terms used to describe fixed values in register and instruction descriptions. The Glossary gives full descriptions of these terms, and each entry in this section includes a link to the corresponding Glossary entry.

Note

In register descriptions, the meaning of some bits depends on the PE state. This affects the definitions of RES0 and RES1, as shown in the Glossary.

The following terms are used to describe bits or fields with fixed values:

RAZ Read-as-Zero. See *Read-As-Zero (RAZ)*.

In diagrams, a RAZ bit can be shown as 0.

RES0 Reserved, Should-be-Zero. See *RES0*.

The RES0 description can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definition covers these cases.

In diagrams, and sometimes in other descriptions, a RES0 bit can be shown as `(0)`. This notation can be expanded for bitfields, so a three-bit RES0 field can be shown as either `(0)(0)(0)` or as `(000)`.

RAO Read-as-One. See *Read-As-One (RAO)*.

In diagrams, a RAO bit can be shown as 1.

RES1 Reserved, Should-be-One. See *RES1*.

The RES1 description can be applied to bits or bitfields that are read-only, or are write-only. The Glossary definition covers these cases.

In diagrams, and sometimes in other descriptions, a RES1 bit can be shown as `(1)`. This notation can be expanded for bitfields, so a three-bit RES1 field can be shown as either `(1)(1)(1)` or as `(111)`.

C5.2 The System instruction class encoding space

Part of the A64 instruction encoding space is assigned to instructions that access the system register space. These instructions provide:

- Access to *System registers*, including the debug registers, that provide system control, and system status information.
- Access to special-purpose registers such as SPSR_ELx, ELR_ELx, and the equivalent fields of the Process State.
- The cache and TLB maintenance instructions and address translation instructions.
- Barriers and the `CLREX` instruction.
- Architectural hint instructions.

This section describes the general model for accessing this functionality.

Note

In AArch32 state this functionality is provided through conceptual coprocessors CP14 and CP15, and in part through CP10 and CP11. These are accessed through a generic coprocessor interface. In ARMv8:

- AArch32 state retains this conceptual coprocessor model, and adds register and operation aliases, to simplify access to this functionality.
- In the instruction encoding descriptions, AArch64 state retains the naming of the instruction arguments as Op1, CRn, CRm, and Op2. However, there is no functional distinction between the Op*n* arguments and the CR*x* arguments.

Principles of the System instruction class encoding describes some general properties of these encodings. *System instruction class encoding overview* on page C5-234 then describes the top-level encoding of these instructions, and the following sections then describe the next level of the encoding hierarchy:

- *Op0==0b00, architectural hints, barriers and CLREX, and PSTATE access* on page C5-235.
- *Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-238.
- *Op0==0b10, Moves to and from debug and trace System registers* on page C5-241.
- *Op0==0b11, Moves to and from non-debug System registers and special-purpose registers* on page C5-243.
- *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

C5.2.1 Principles of the System instruction class encoding

In ARMv8, an encoding in the System instruction space is identified by a set of arguments, `Op0`, `Op1`, `CRn`, `CRm`, and `Op2`. These form an encoding hierarchy, where:

`Op0` Defines the top-level division of the encoding space, see *System instruction class encoding overview* on page C5-234.

`Op1` Identifies the lowest Exception level at which the encoding is accessible, as follows:

- **Accessible at EL0** `Op1` has the value 3.
- **Accessible at EL1** `Op1` has the value 0, 1, or 2. The value is the same as the `Op1` value used to access the equivalent AArch32 register.
- **Accessible at EL2** `Op1` has the value 4.
- **Accessible at EL3** `Op1` has the value 6.

ARM strongly recommends that implementers adopt this use of `Op1` when using the IMPLEMENTATION DEFINED regions of the encoding space described in *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

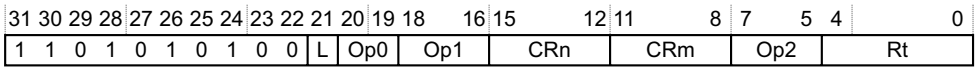
C5.2.2 System instruction class encoding overview

The encoding of the System instruction class describes each instruction as being either:

- A transfer to a System register. This is a System instruction with the semantics of a write.
- A transfer from a System register. This is a System instruction with the semantics of a read.

A System instruction that initiate an operation operates as if it was making a transfer to a register.

In the AArch64 instruction set, the decode structure for the System instruction class is:



The value of `L` indicates the transfer direction:

0 Transfer to system register.

1 Transfer from system register.

The `Op0` field is the top level encoding of the System instruction type. Its possible values are:

`0b00` These encodings provide:

- Instructions with an immediate field for accessing PSTATE, the current PE state.
- The architectural hint instructions.
- Barriers and the `CLREX` instruction.

For more information about these encodings, see *Op0==0b00, architectural hints, barriers and CLREX, and PSTATE access* on page C5-235.

`0b01` These encodings provide the cache maintenance, TLB maintenance, and address translation instructions.

Note

These are equivalent to operations in the AArch32 CP15 space.

For more information, see *Op0==0b01, cache maintenance, TLB maintenance, and address translation instructions* on page C5-238.

`0b10` These encodings provide moves to and from:

- Legacy AArch32 System registers for execution environments, to provide access to these registers from higher exception levels that are using AArch64.
- Debug and trace registers.

Note

These are equivalent to the registers in the AArch32 CP14 space,.

For more information, see *Op0==0b10, Moves to and from debug and trace System registers* on page C5-241.

`0b11` These encodings provide:

- Moves to and from System registers for software execution in Non-debug state. These registers provide Non-debug state system control, and system status information.

  Note

  These are equivalent to the registers in the AArch32 CP15 space,.

- Instructions for accessing special-purpose registers.

For more information, see *Instructions for accessing special-purpose registers* on page C5-249 and *Instructions for accessing non-debug System registers* on page C5-243.

UNDEFINED behaviors

In the System register instruction encoding space, the following principles apply:

- All unallocated encodings are treated as UNDEFINED.
- All encodings with L==1 and Op0==0b0x are UNDEFINED, except for encodings in the area reserved for IMPLEMENTATION DEFINED use, see *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

For registers and operations that are accessible from a particular Exception level, any attempt to access those registers from a lower Exception level is UNDEFINED.

If a particular Exception level:

- Defines a register to be RO then any attempt to write to that register, at that Exception level, is UNDEFINED. This means that any access to that register with L==0 is UNDEFINED.
- A register to be WO then any attempt to read from that register, at that Exception level, is UNDEFINED. This means that any access to that register with L==1 is UNDEFINED.

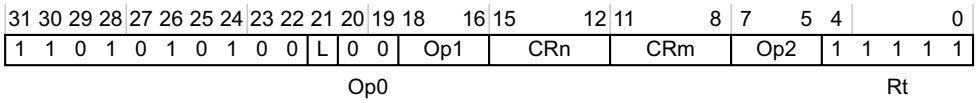
For IMPLEMENTATION DEFINED encoding spaces, the treatment of the encodings is IMPLEMENTATION DEFINED, but see the recommendation in *Principles of the System instruction class encoding* on page C5-233.

C5.2.3 Op0==0b00, architectural hints, barriers and CLREX, and PSTATE access

The different groups of System register instructions with Op0==0b00:

- Are identified by the value of CRn.
- Are always encoded with a value of 0b11111 in the Rt field.

The encoding of these instructions is:



The encoding of the CRn field is as follows:

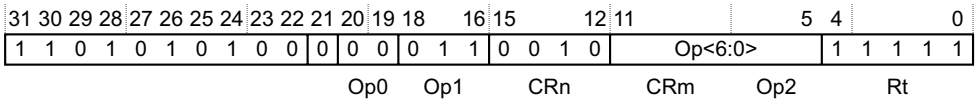
0b0010 See *Architectural hint instructions*.

0b0011 See *Barriers and CLREX* on page C5-236.

0b0100 See *Instructions for accessing the PSTATE fields* on page C5-237.

Architectural hint instructions

The architectural hint instructions are identified by CRn having the value 0b0010. The encoding of these instructions is:



The value of Op<6:0>, formed by concatenating the CRm and Op2 fields, determines the hint instruction as follows:

0b0000000 NOP instruction. This has no effect on architectural state other than to advance the PC.

0b0000001 YIELD instruction.

0b0000010 WFE instruction.

0b0000011 WFI instruction.

0b0000100 SEV instruction.

0b0000101 SEVL instruction.

0b0000110-0b1111111
Unallocated values. These encodings behave as NOPs.

Note

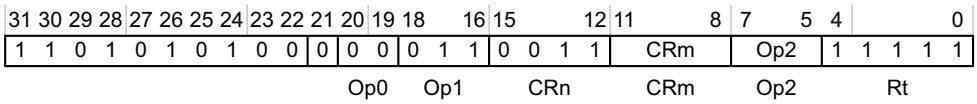
- Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.
- The operation of the A64 instructions for architectural hints are identical to the corresponding A32 and T32 instructions.

For more information about:

- The WFE, WFI, SEV, and SEVL instructions, see *Mechanisms for entering a low-power state* on page D1-1503.
- The YIELD instruction, see *Software control features and EL0* on page B1-64.

Barriers and CLREX

The barriers and CLREX instructions are identified by CRn having the value 0b0011. The encoding of these instructions is:



The value of Op2 determines the instruction, as follows. For the DSB and DMB instructions, CRm controls the instruction options.

0b010 CLREX instruction. The value of CRm is ignored.

0b100 DSB instruction. The value of CRm sets the option type, see Table C5-1.

0b101 DMB instruction. The value of CRm sets the option type, see Table C5-1.

0b110 ISB instruction. The value of CRm is ignored.

0b000, 0b001, 0b011, 0b111
UNDEFINED.

Note

Instruction encodings with bits[4:0] not set to 0b11111 are UNDEFINED.

Table C5-1 shows the CRm encodings for the data barrier option types.

Table C5-1 CRm encoding for DMB and DSB instructions

CRm value	Option, for DMB and DSB	Meaning
0001	OSHLD	Outer Shareable, load
0010	OSHST	Outer Shareable, store
0011	OSH	Outer Shareable, all
0101	NSHLD	Non-shareable, load
0110	NSHST	Non-shareable, store
0111	NSH	Non-shareable, all
1001	ISHLD	Inner Shareable, load
1010	ISHST	Inner Shareable, store
1011	ISH	Inner Shareable, all

Table C5-1 CRm encoding for DMB and DSB instructions (continued)

CRm value	Option, for DMB and DSB	Meaning
1101	LD	Full system, load
1110	ST	Full system, store
0000, 0100, 1000, 1111	SYS	Full system, all

Note

The operation of the A64 instructions for barriers and CLREX are identical to the corresponding A32 and T32 instructions.

For more information about:

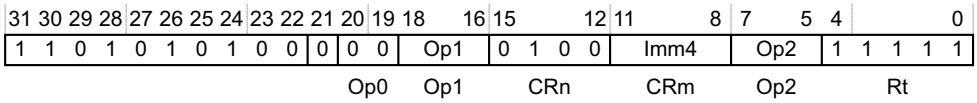
- The barrier instructions, see *Memory barriers* on page B2-85.
- The CLREX instruction, see *Synchronization and semaphores* on page B2-99.

Instructions for accessing the PSTATE fields

The A64 instruction set provides instructions that can be used to modify PSTATE fields directly. These instructions are:

```
MSR DAIFSet, #Imm4    ; Used to set any or all of DAIF to 1
MSR DAIFClr, #Imm4    ; Used to clear any or all of DAIF to 0
MSR SPSel, #Imm1      ; Used to select the Stack Pointer, between SP_EL0 and SP_ELx
```

The PSTATE field update instructions are identified by CRn having the value 0b0100. The encoding of these instructions is:



The value of Op2 selects the instruction form, which defines the constraints on the values of the Op1 and Imm4 arguments, as follows:

Op2==0b101 Selects the MSR SPSel instruction.

Op1 must be 0b000.

This instruction is accessible at EL1 or higher.

Imm4<0> selects the accessed stack pointer, as follows:

0 Selects SP_EL0.

1 Selects *SP_ELx* on page AppxJ-5173, where *x* is the number of the current Exception level, 1, 2, or 3.

Imm4<3:1> are RES0.

Op2==0b110 Selects the MSR DAIFSet instruction, that sets the specified PSTATE.{D, A, I, F} bits to 1.

Op1 must be 0b011.

This instruction is accessible at EL1 or higher, and when the value of the SCTLR_EL1.UMA bit is 1 it is also accessible at EL0.

Imm4 determines which of the PSTATE.{D, A, I, F} bits are set to 1, as follows:

Imm4<3> If this bit is set to 1 then the D bit is set to 1, otherwise the D bit is not changed.

Imm4<2> If this bit is set to 1 then the A bit is set to 1, otherwise the A bit is not changed.

Imm4<1> If this bit is set to 1 then the I bit is set to 1, otherwise the I bit is not changed.

Imm4<0> If this bit is set to 1 then the F bit is set to 1, otherwise the F bit is not changed.

`Op2==0b111` Selects the `MSR DAIFClr` instruction, that clears the specified PSTATE.{D, A, I, F} bits to 0.

`Op1` must be `0b011`.

This instruction is accessible at EL1 or higher, and when the value of the SCTLR_EL1.UMA bit is 1 it is also accessible at EL0.

`Imm4` determines which of the PSTATE.{D, A, I, F} bits is cleared to 0, as follows:

`Imm4<3>` If this bit is set to 1 then the D bit is cleared to 0, otherwise the D bit is not changed.

`Imm4<2>` If this bit is set to 1 then the A bit is cleared to 0, otherwise the A bit is not changed.

`Imm4<1>` If this bit is set to 1 then the I bit is cleared to 0, otherwise the I bit is not changed.

`Imm4<0>` If this bit is set to 1 then the F bit is cleared to 0, otherwise the F bit is not changed.

All other combinations of `Op1` and `Op2` are reserved, and the corresponding instructions are UNDEFINED.

Note

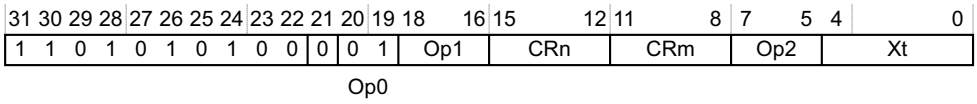
For PSTATE updates, instruction encodings with bits[4:0] not set to `0b11111` are UNDEFINED.

Writes to PSTATE.{D, A, I, F} occur in program order without the need for additional synchronization. Changing PSTATE.SPSel to use EL0 synchronizes any updates to SP_EL0 that have been written by an `MSR` to SP_EL0, without the need for additional synchronization.

For more information about PSTATE, see *Process state, PSTATE* on page D1-1413.

C5.2.4 `Op0==0b01`, cache maintenance, TLB maintenance, and address translation instructions

The System instructions are encoded with `Op0==0b01`. The different groups of System instructions are identified by the values of `CRn` and `CRm`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



The grouping of these instructions depending on the `CRn` and `CRm` fields is as follows:

`CRn==7` The instruction group is determined by the value of `CRm`, as follows:

- `CRm=={1, 5}` Instruction cache maintenance instructions.
- `CRm==4` Data cache zero operation.
- `CRm=={6, 10, 11, 14}` Data cache maintenance instructions.

  See *Cache maintenance instructions, and data cache zero* on page C5-239.
- `CRm==8` See *Address translation instructions* on page C5-239.

`CRn==8` See *TLB maintenance instructions* on page C5-240.

`CRn=={11, 15}` See *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

Cache maintenance instructions, and data cache zero

Table C5-2 lists the Cache maintenance instructions and their encodings. Instructions that take an argument include `Xt` in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as `0b11111`.

Table C5-2 Cache maintenance instructions

Instruction	Access instruction encoding				Notes
	Op1	CRn	CRm	Op2	
Instruction cache maintenance instructions					
IC IALLUIS	0	7	1	0	Accessible from EL1 or higher.
IC IALLU			5	0	
IC IVAU, `Xt`	3	7	5	1	When SCTLR_EL1.UCI == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.
Data cache maintenance instructions					
DC IVAC, `Xt`	0	7	6	1	Accessible from EL1 or higher.
DC ISW, `Xt`				2	
DC CSW, `Xt`			10	2	
DC CISW, `Xt`			14	2	
DC CVAC, `Xt`	3	7	10	1	When SCTLR_EL1.UCI == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.
DC CVAU, `Xt`			11	1	
DC CIVAC, `Xt`			14	1	
Data cache zero operation					
DC ZVA, `Xt`	3	7	4	1	When SCTLR_EL1.UCI == 1, accessible from EL0 or higher. Otherwise, accessible from EL1 or higher.

For more information about these instructions, see *Overview of the cache maintenance instructions* on page D3-1604 and *Cache maintenance instructions* on page D3-1608.

Address translation instructions

Table C5-3 lists the Address translation instructions and their encodings. The syntax of the instructions includes `Xt`, that provides the address to be translated.

Table C5-3 Address translation instructions

Instruction	Access instruction encoding				Notes
	Op1	CRn	CRm	Op2	
AT S1E1R, `Xt`	0	7	8	0	Accessible from EL1 or higher.
AT S1E1W, `Xt`				1	
AT S1E0R, `Xt`				2	
AT S1E0W, `Xt`				3	

Table C5-3 Address translation instructions (continued)

Instruction	Access instruction encoding				Notes
	Op1	CRn	CRm	Op2	
AT S1E2R, Xt	4	7	8	0	Accessible from EL2 or higher.
AT S1E2W, Xt				1	
AT S12E1R, Xt				4	
AT S12E1W, Xt				5	
AT S12E0R, Xt				6	
AT S12E0W, Xt				7	
AT S1E3R, Xt	6	7	8	0	Accessible only from EL3.
AT S1E3W, Xt				1	

For more information about these instructions, see *Address translation instructions* on page D4-1683.

TLB maintenance instructions

Table C5-4 lists the TLB maintenance instructions and their encodings. Instructions that take an argument include Xt in the instruction syntax. For instructions that do not take an argument, the Xt field is encoded as 0b11111.

Table C5-4 TLB maintenance instructions

Instruction	Access instruction encoding				Notes
	Op1	CRn	CRm	Op2	
TLBI VMALLE1IS	0	8	3	0	Accessible from EL1 or higher.
TLBI VAE1IS, Xt				1	
TLBI ASIDE1IS, Xt				2	
TLBI VAAE1IS, Xt				3	
TLBI VALE1IS, Xt				5	
TLBI VAALE1IS, Xt				7	
TLBI VMALLE1			7	0	Accessible from EL1 or higher.
TLBI VAE1, Xt				1	
TLBI ASIDE1, Xt				2	
TLBI VAAE1, Xt				3	
TLBI VALE1, Xt				5	
TLBI VAALE1, Xt				7	

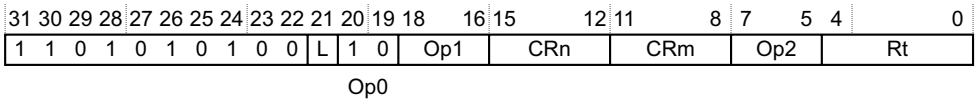
Table C5-4 TLB maintenance instructions (continued)

Instruction	Access instruction encoding				Notes
	Op1	CRn	CRm	Op2	
TLBI IPAS2E1IS, Xt	4	8	0	1	Accessible from EL2 or higher.
TLBI IPAS2LE1IS, Xt				5	
TLBI ALLE2IS			3	0	
TLBI VAE2IS, Xt				1	
TLBI ALLE1IS				4	
TLBI VALE2IS, Xt				5	
TLBI VMALLS12E1IS				6	
TLBI IPAS2E1, Xt			4	1	
TLBI IPAS2LE1, Xt				5	
TLBI ALLE2			7	0	
TLBI VAE2, Xt				1	
TLBI ALLE1				4	
TLBI VALE2, Xt				5	
TLBI VMALLS12E1				6	
TLBI ALLE3IS	6	8	3	0	Accessible only from EL3.
TLBI VAE3IS, Xt				1	
TLBI VALE3IS, Xt				5	
TLBI ALLE3			7	0	
TLBI VAE3, Xt				1	
TLBI VALE3, Xt				5	

For more information about these instructions, see *TLB maintenance instructions* on page D4-1735.

C5.2.5 Op0==0b10, Moves to and from debug and trace System registers

The instructions that move data to and from the debug, Execution environment, and trace system registers are encoded with Op0==0b10. This means the encoding of these instructions is:



Note

These encodings access the registers that are equivalent to the AArch32 CP14 registers.

The value of Op1 provides the next level of decode of these instructions, as follows:

Op1 == {0, 3, 4}

Debug. See *Instructions for accessing debug System registers*

Op1 == 1 Trace. See the appropriate trace architecture specification.

Instructions for accessing debug System registers

The instructions for accessing debug System registers are:

```
MSR <System register>, Xt    ; Write to System register
MRS Xt, <System register>    ; Read from System register
```

Where `<System_register>` is the register name, for example MDCCSR_EL0.

This section includes only the System register access encodings for which both:

- `Op0` is `0b10`.
- The value of `Op1` is one of {0, 3, 4}.

Note

These encodings access the registers that are equivalent to the AArch32 CP14 registers.

Table C5-5 shows the mapping of the System register encodings for debug System register access.

Table C5-5 System instruction encodings for debug System register access

Register	Access instruction encoding				Permitted accesses
	Op1	CRn	CRm	Op2	
OSDTRRX_EL1	0	0	0	2	RW
MDCCINT_EL1			2	0	RW
MDSCR_EL1				2	RW
OSDTRTX_EL1			3	2	RW
OSECCR_EL1			6	2	RW
DBGBVR<n>_EL1			0-15[a]	4	RW
DBGBCR<n>_EL1			0-15[a]	5	RW
DBGWVR<n>_EL1			0-15[a]	6	RW
DBGWCR<n>_EL1			0-15[a]	7	RW
MDRAR_EL1		1	0	0	RO
OSLAR_EL1				4	WO
OSLSR_EL1			1	4	RO
OSDLR_EL1			3	4	RW
DBGPRCR_EL1			4	4	RW
DBGCLAIMSET_EL1		7	8	6	RW
DBGCLAIMCLR_EL1			9	6	RW
DBGAUTHSTATUS_EL1			14	6	RO

Table C5-5 System instruction encodings for debug System register access (continued)

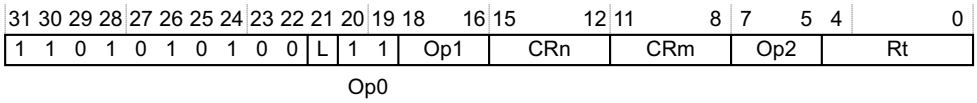
Register	Access instruction encoding				Permitted accesses
	Op1	CRn	CRm	Op2	
MDCCSR_EL0	3	0	1	0	RO
DBGDTR_EL0			4	0	RW
DBGDTRRX_EL0			5	0	RO
DBGDTRTX_EL0					WO
DBGVCR32_EL2	4	0	7	0	RW

a. Unimplemented breakpoint and watchpoint register access instructions are unallocated. If EL2 is not implemented or breakpoint *n* is not context-aware, DBGBXVR*n*_ EL1 is unallocated. CRm encodes *n*, the breakpoint or watchpoint number.

For more information see *Mapping of the System registers between the Execution states* on page D1-1515.

C5.2.6 `Op0==0b11`, Moves to and from non-debug System registers and special-purpose registers

The instructions that move data to and from non-debug system registers are encoded with `Op0==0b11`, except that some of this encoding space is reserved for IMPLEMENTATION DEFINED functionality. The encoding of these instructions is:



The value of `CRn` provides the next level of decode of these instructions, as follows:

`CRn==`**{0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14}**
See *Instructions for accessing non-debug System registers*.

`CRn==`**4** See *Instructions for accessing special-purpose registers* on page C5-249.

`CRn==`**{11, 15}** See *Reserved control space for IMPLEMENTATION DEFINED functionality* on page C5-251.

Instructions for accessing non-debug System registers

The A64 instructions for accessing System registers are:

```
MSR <System register>, Xt    ; Write to System register
MRS Xt, <System register>    ; Read from System register
```

Where `<System_register>` is the register name, for example MIDR_EL1.

This section includes only the System register access encodings for which both:

- `Op0` is `0b11`.
- The value of `CRn` is one of {0, 1, 2, 3, 5, 6, 7, 9, 10, 12, 13, 14}.

Note

These encodings access the registers that are equivalent to the AArch32 CP15 registers.

The instruction encoding for these accesses is:

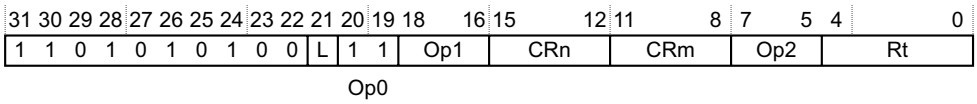


Table C5-6 shows the encodings of the register access instructions. For these registers, `CRn` often indicates register grouping, and therefore `CRn` is given as the first column of the encoding. Registers appended with [63:0] are 64-bit registers. All other registers are 32-bit registers for which bits [63:32] of the 64-bit register value are RES0.

Table C5-6 System instruction encodings for System register accesses

Register accessed	Access instruction encoding				Notes
	CRn	Op1	CRm	Op2

Timer registers					
CNTKCTL_EL1	14	0	1	0	RW.

Table C5-6 System instruction encodings for System register accesses (continued)

Register accessed	Access instruction encoding				Notes
	CRn	Op1	CRm	Op2	
CNTFRQ_EL0	14	3	0	0	RO at EL1 but can be written at the highest Exception Level implemented. Configurable to enable access at EL0.
CNTPCT_EL0[63:0]				1	RO. Configurable whether accesses at EL0 are permitted.
CNTVCT_EL0[63:0]				2	
CNTP_TVAL_EL0			2	0	Configurable whether accesses at EL0 are permitted.
CNTP_CTL_EL0				1	
CNTP_CVAL_EL0[63:0]				2	
CNTV_TVAL_EL0			3	0	Configurable whether accesses at EL0 are permitted.
CNTV_CTL_EL0				1	
CNTV_CVAL_EL0[63:0]				2	
CNTHCTL_EL2	14	4	1	0	RW.
CNTHP_TVAL_EL2	14	4	2	0	RW.
CNTHP_CTL_EL2				1	
CNTHP_CVAL_EL2[63:0]				2	
CNTPS_TVAL_EL1	14	7	2	0	Accessible at EL3. Configurable whether Secure accesses at EL1 are permitted.
CNTPS_CTL_EL1				1	
CNTPS_CVAL_EL1[63:0]				2	
The following registers are defined to allow access from AArch64 state to registers that are only used in AArch32 state					
SDER32_EL3	1	6	1	1	If EL1 cannot use AArch32, this register is UNDEFINED.
DACR32_EL2	3	4	0	0	If EL1 cannot use AArch32, this register is UNDEFINED.
IFSR32_EL2	5	4	0	1	If EL1 cannot use AArch32, this register is UNDEFINED.
FPEXC32_EL2			3	0	If EL1 cannot use AArch32, this register is UNDEFINED.

Instructions for accessing special-purpose registers

The A64 instructions for accessing special-purpose registers are:

```
MSR <special-purpose register>, Xt    ; Write to special-purpose register
MRS Xt, <special-purpose register>    ; Read from special-purpose register
```

For these accesses, `CRn` has the value 4. The encoding for special-purpose register accesses is:

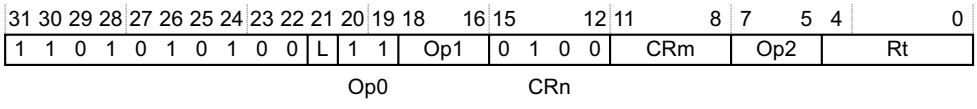

Table C5-7 lists the encodings for `Op1`, `CRm`, and `Op2` fields for accesses to the special-purpose registers in AArch64.

Table C5-7 Special-purpose register accesses

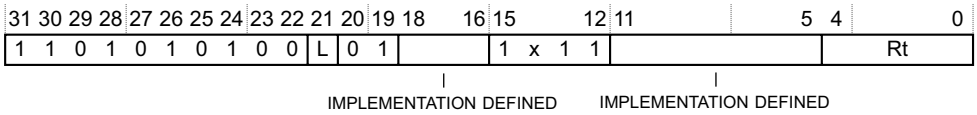
Register	Access instruction encoding:			Notes
	Op1	CRm	Op2	
SPSR_EL1	0	0	0	Accessible from EL1 or higher.
ELR_EL1			1	
SP_EL0		1	0	Accessible from EL1 or higher. If SP_EL0 is the current stack pointer then the access is UNDEFINED.
SPSel		2	0	Accessible from EL1 or higher.
CurrentEL			2	RO. Accessible from EL1 or higher.
DAIF	3	2	1	Configurable whether accesses at EL0 are permitted.
NZCV			0	Accessible from EL0 or higher.
FPCR		4	0	Accessible from EL0 or higher.
FPSR			1	
DSPSR_EL0		5	0	Accessible only in Debug state, from EL0 or higher.
DLR_EL0			1	
SPSR_EL2	4	0	0	Accessible from EL2 or higher.
ELR_EL2			1	
SP_EL1		1	0	
SPSR_irq		3	0	
SPSR_abt			1	
SPSR_und			2	
SPSR_fiq			3	
SPSR_EL3	6	0	0	Accessible from EL3 or higher.
ELR_EL3			1	
SP_EL2		1	0	

For the accesses to the special-purpose registers shown in Table C5-7:

- Any write to the FPCR must be synchronized, by a *Context synchronization operation*, before its effect on subsequent instructions can be relied upon.
- All other reads and writes to the registers appear to occur in program order relative to other instructions.

C5.2.7 Reserved control space for IMPLEMENTATION DEFINED functionality

The A64 instruction set reserves the following space for IMPLEMENTATION DEFINED instructions:

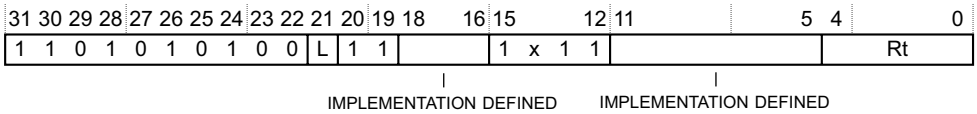


The value of L defines the use of Rt as follows:

0 Rt is an argument supplied to the instruction.

1 Rt is a result returned by the instruction.

The A64 instruction set reserves the following space for IMPLEMENTATION DEFINED registers:



The value of L defines the access type and the use of Rt as follows:

0 Write the value in Rt to the IMPLEMENTATION DEFINED register.

L==1 Read the value of the IMPLEMENTATION DEFINED register to Rt.

C5.3 PSTATE and special purpose registers

This section describes the following registers:

- CurrentEL, that software can read to determine the current Exception level.
- DAIF, that specifies the current interrupt mask bits.
- DLR_EL0, that holds the address to return to for a return from Debug state.
- DSPSR_EL0, that holds process state on entry to Debug state.
- ELR_EL1, that holds the address to return to for an exception return from EL1.
- ELR_EL2, that holds the address to return to for an exception return from EL2.
- ELR_EL3, that holds the address to return to for an exception return from EL3.
- FPCR, that provides control of floating-point operation.
- FPSR, that provides floating-point status information.
- NZCV, that holds the condition flags.
- SP_EL0, that holds the stack pointer for EL0.
- SP_EL1, that holds the stack pointer for EL1.
- SP_EL2, that holds the stack pointer for EL2.
- SP_EL3, that holds the stack pointer for EL3.
- SPSel, that at EL1 or higher selects between the SP for the current Exception level and SP_EL0.
- SPSR_abt, that holds process state on taking an exception to AArch32 Abort mode.
- SPSR_EL1, that holds process state on taking an exception to AArch64 EL1.
- SPSR_EL2, that holds process state on taking an exception to AArch64 EL2.
- SPSR_EL3, that holds process state on taking an exception to AArch64 EL3.
- SPSR_fiq, that holds process state on taking an exception to AArch32 FIQ mode.
- SPSR_irq, that holds process state on taking an exception to AArch32 IRQ mode.
- SPSR_und, that holds process state on taking an exception to AArch32 Undefined mode.

The PSRs hold the PE state from immediately before taking the exception or entering Debug state. This means they hold the state required for the return from Debug state, or for the exception return.

C5.3.1 CurrentEL, Current Exception Level

The CurrentEL characteristics are:

Purpose

Holds the current exception level.

This register is part of the Process state registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RO	RO	RO	RO	RO

A write to the CurrentEL register is UNDEFINED.

Configurations

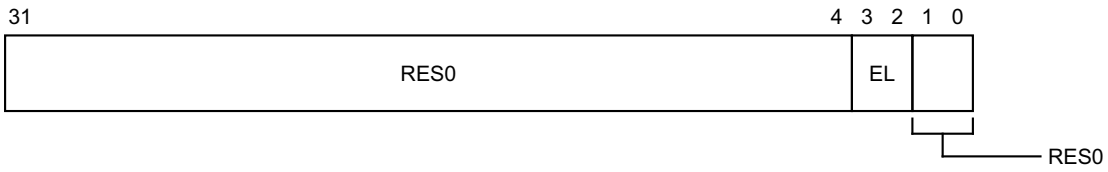
There are no configuration notes.

Attributes

CurrentEL is a 32-bit register.

Field descriptions

The CurrentEL bit assignments are:



Bits [31:4]

Reserved, RES0.

EL, bits [3:2]

Current exception level. Possible values of this field are:

00 EL0

01 EL1

10 EL2

11 EL3

Resets to an IMPLEMENTATION DEFINED value.

Bits [1:0]

Reserved, RES0.

Accessing the CurrentEL

To access the CurrentEL:

```
MRS <Xt>, CurrentEL ; Read CurrentEL into Xt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0010	010

C5.3.2 DAIF, Interrupt Mask Bits

The DAIF characteristics are:

Purpose

Allows access to the interrupt mask bits.

This register is part of the Process state registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-RW	RW	RW	RW	RW	RW

This register is accessible at EL0 when SCTLR_EL1.UMA is set to 1.

Configurations

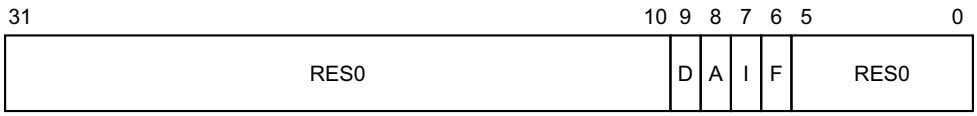
There are no configuration notes.

Attributes

DAIF is a 32-bit register.

Field descriptions

The DAIF bit assignments are:



Bits [31:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are not masked.

`1` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are masked.

When the target exception level of the debug exception is not than the current exception level, the exception is not masked by this bit.

Resets to 1.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Resets to 1.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Resets to 1.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Resets to 1.

Bits [5:0]

Reserved, RES0.

Accessing the DAIF

To access the DAIF:

```
MRS <Xt>, DAIF ; Read DAIF into Xt
MSR DAIF, <Xt> ; Write Xt to DAIF
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0010	001

C5.3.3 DLR_EL0, Debug Link Register

The DLR_EL0 characteristics are:

Purpose

In Debug state, holds the address to restart from.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

Configurations

DLR_EL0[31:0] is architecturally mapped to AArch32 register DLR.

Attributes

DLR_EL0 is a 64-bit register.

Field descriptions

DLR_EL0 is a member of multiple register groups and is defined elsewhere. For the full definition, see *DLR_EL0, Debug Link Register* on page D7-2016.

Accessing the DLR_EL0

To access the DLR_EL0:

```
MRS <Xt>, DLR_EL0 ; Read DLR_EL0 into Xt
MSR DLR_EL0, <Xt> ; Write Xt to DLR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0101	001

C5.3.4 DSPSR_EL0, Debug Saved Program Status Register

The DSPSR_EL0 characteristics are:

Purpose

Holds the saved processor state on entry to Debug state.

This register is part of:

- the Debug registers functional group
- the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Access to this register is from Debug state only. During normal execution this register is UNALLOCATED.

Configurations

DSPSR_EL0 is architecturally mapped to AArch32 register DSPSR.

Attributes

DSPSR_EL0 is a 32-bit register.

Field descriptions

DSPSR_EL0 is a member of multiple register groups and is defined elsewhere. For the full definition, see *DSPSR_EL0, Debug Saved Program Status Register* on page D7-2017.

Accessing the DSPSR_EL0

To access the DSPSR_EL0:

```
MRS <Xt>, DSPSR_EL0 ; Read DSPSR_EL0 into Xt
MSR DSPSR_EL0, <Xt> ; Write Xt to DSPSR_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0101	000

C5.3.5 ELR_EL1, Exception Link Register (EL1)

The ELR_EL1 characteristics are:

Purpose

When taking an exception to EL1, holds the address to return to.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

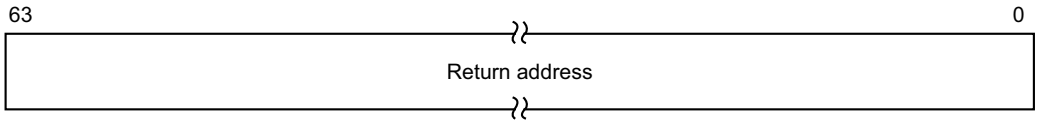
There are no configuration notes.

Attributes

ELR_EL1 is a 64-bit register.

Field descriptions

The ELR_EL1 bit assignments are:



Bits [63:0]

Return address.

Accessing the ELR_EL1

To access the ELR_EL1:

```
MRS <Xt>, ELR_EL1 ; Read ELR_EL1 into Xt
MSR ELR_EL1, <Xt> ; Write Xt to ELR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0000	001

C5.3.6 ELR_EL2, Exception Link Register (EL2)

The ELR_EL2 characteristics are:

Purpose

When taking an exception to EL2, holds the address to return to.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

When EL2 is in AArch32 Execution state and an exception is taken from EL0, EL1, or EL2 to EL3 and AArch64 execution, the upper 32-bits of ELR_EL2 are either set to 0 or hold the same value that they did before AArch32 execution. Which option is adopted is determined by an implementation, and might vary dynamically within an implementation. Correspondingly software must regard the value as being an UNKNOWN choice between the two values.

Configurations

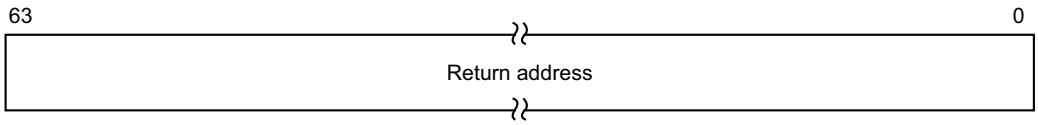
ELR_EL2 is architecturally mapped to AArch32 register ELR_hyp.

Attributes

ELR_EL2 is a 64-bit register.

Field descriptions

The ELR_EL2 bit assignments are:



Bits [63:0]

Return address.

Accessing the ELR_EL2

To access the ELR_EL2:

```
MRS <Xt>, ELR_EL2 ; Read ELR_EL2 into Xt
MSR ELR_EL2, <Xt> ; Write Xt to ELR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0000	001

C5.3.7 ELR_EL3, Exception Link Register (EL3)

The ELR_EL3 characteristics are:

Purpose

When taking an exception to EL3, holds the address to return to.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

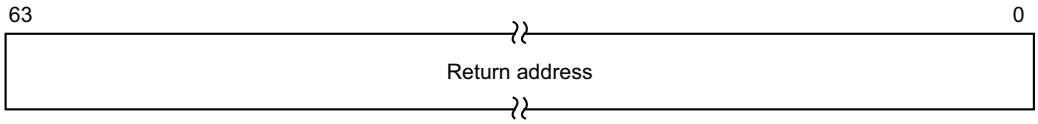
There are no configuration notes.

Attributes

ELR_EL3 is a 64-bit register.

Field descriptions

The ELR_EL3 bit assignments are:



Bits [63:0]

Return address.

Accessing the ELR_EL3

To access the ELR_EL3:

```
MRS <Xt>, ELR_EL3 ; Read ELR_EL3 into Xt
MSR ELR_EL3, <Xt> ; Write Xt to ELR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0100	0000	001

C5.3.8 FPCR, Floating-point Control Register

The FPCR characteristics are:

Purpose

Controls floating-point extension behavior.

This register is part of:

- the Special purpose registers functional group
- the Floating-point registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Configurations

The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

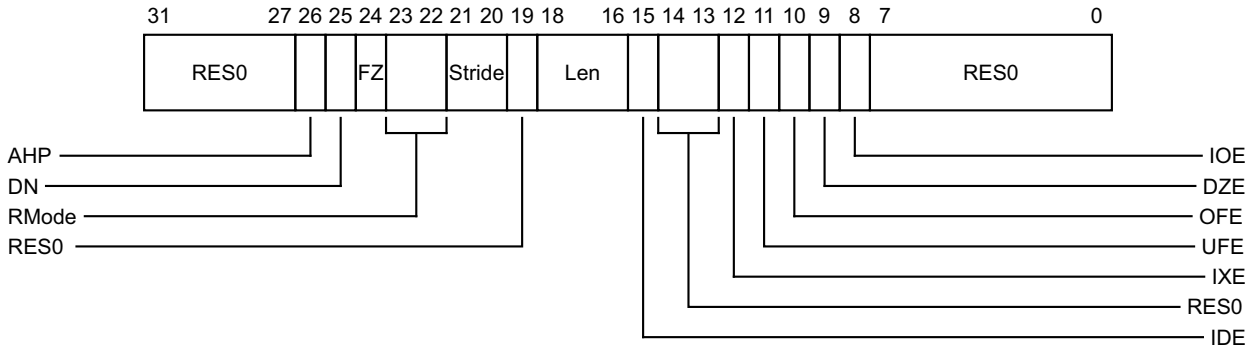
It is IMPLEMENTATION DEFINED whether the Len and Stride fields can be programmed to non-zero values, which will cause some AArch32 floating-point instruction encodings to be UNDEFINED, or whether these fields are RAZ.

Attributes

FPCR is a 32-bit register.

Field descriptions

The FPCR bit assignments are:



Bits [31:27]

Reserved, RES0.

AHP, bit [26]

Alternative half-precision control bit:

0 IEEE half-precision format selected.

1 Alternative half-precision format selected.

DN, bit [25]

Default NaN mode control bit:

0 NaN operands propagate through to the output of a floating-point operation.

1 Any operation involving one or more NaNs returns the Default NaN.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

FZ, bit [24]

Flush-to-zero mode control bit:

0 Flush-to-zero mode disabled. Behavior of the floating-point system is fully compliant with the IEEE 754 standard.

1 Flush-to-zero mode enabled.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

RMode, bits [23:22]

Rounding Mode control field. The encoding of this field is:

00 Round to Nearest (RN) mode

01 Round towards Plus Infinity (RP) mode

10 Round towards Minus Infinity (RM) mode

11 Round towards Zero (RZ) mode.

The specified rounding mode is used by both scalar and Advanced SIMD floating-point instructions.

Stride, bits [21:20]

This field is ignored during AArch64 execution.

Bit [19]

Reserved, RES0.

Len, bits [18:16]

This field is ignored during AArch64 execution.

IDE, bit [15]

Input Denormal exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IDC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IDC bit. The trap handling software can decide whether to set the FPSR.IDC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

Bits [14:13]

Reserved, RES0.

IXE, bit [12]

Inexact exception trap enable. Possible values are:

0 Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IXC bit is set to 1.

1 Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IXC bit. The trap handling software can decide whether to set the FPSR.IXC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

UFE, bit [11]

Underflow exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.UFC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.UFC bit. The trap handling software can decide whether to set the FPSR.UFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

OFE, bit [10]

Overflow exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.OFC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.OFC bit. The trap handling software can decide whether to set the FPSR.OFC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

DZE, bit [9]

Division by Zero exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.DZC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.DZC bit. The trap handling software can decide whether to set the FPSR.DZC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

IOE, bit [8]

Invalid Operation exception trap enable. Possible values are:

`0` Untrapped exception handling selected. If the floating-point exception occurs then the FPSR.IOC bit is set to 1.

`1` Trapped exception handling selected. If the floating-point exception occurs, the PE does not update the FPSR.IOC bit. The trap handling software can decide whether to set the FPSR.IOC bit to 1.

The value of this bit controls both scalar and Advanced SIMD floating-point arithmetic.

If the implementation does not support this exception, this bit is RES0.

Bits [7:0]

Reserved, RES0.

Accessing the FPCR

To access the FPCR:

```
MRS <Xt>, FPCR ; Read FPCR into Xt
MSR FPCR, <Xt> ; Write Xt to FPCR
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0100	000

C5.3.9 FPSR, Floating-point Status Register

The FPSR characteristics are:

Purpose

Provides floating-point system status information.

This register is part of:

- the Special purpose registers functional group
- the Floating-point registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Configurations

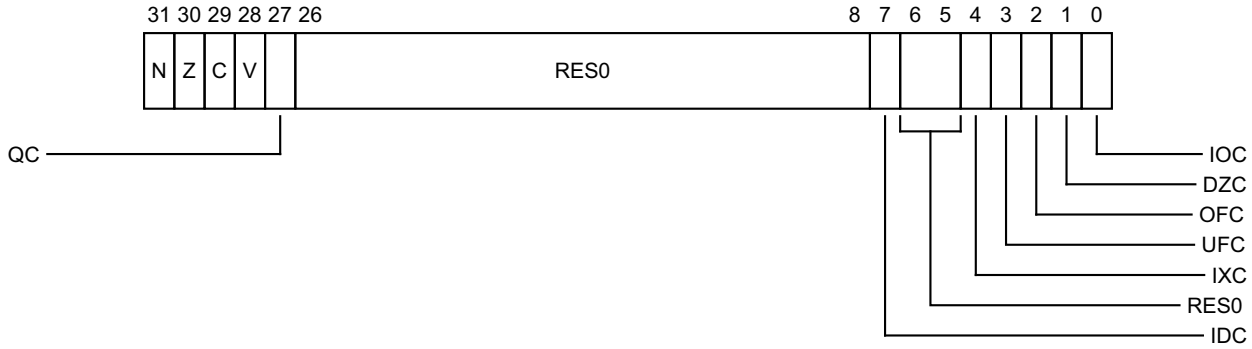
The named fields in this register map to the equivalent fields in the AArch32 FPSCR.

Attributes

FPSR is a 32-bit register.

Field descriptions

The FPSR bit assignments are:



N, bit [31]

Negative condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.N flag instead.

Z, bit [30]

Zero condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.Z flag instead.

C, bit [29]

Carry condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.C flag instead.

V, bit [28]

Overflow condition flag for AArch32 floating-point comparison operations. AArch64 floating-point comparisons set the PSTATE.V flag instead.

QC, bit [27]

Cumulative saturation bit, Advanced SIMD only. This bit is set to 1 to indicate that an Advanced SIMD integer operation has saturated since 0 was last written to this bit.

Bits [26:8]

Reserved, RES0.

IDC, bit [7]

Input Denormal cumulative exception bit. This bit is set to 1 to indicate that the Input Denormal exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IDE bit. This bit is only set to 1 to indicate an exception if FPCR.IDE is 0, or if trapping software sets it.

Bits [6:5]

Reserved, RES0.

IXC, bit [4]

Inexact cumulative exception bit. This bit is set to 1 to indicate that the Inexact exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IXE bit. This bit is only set to 1 to indicate an exception if FPCR.IXE is 0, or if trapping software sets it.

UFC, bit [3]

Underflow cumulative exception bit. This bit is set to 1 to indicate that the Underflow exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.UFE bit. This bit is only set to 1 to indicate an exception if FPCR.UFE is 0, or if trapping software sets it.

OFC, bit [2]

Overflow cumulative exception bit. This bit is set to 1 to indicate that the Overflow exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.OFE bit. This bit is only set to 1 to indicate an exception if FPCR.OFE is 0, or if trapping software sets it.

DZC, bit [1]

Division by Zero cumulative exception bit. This bit is set to 1 to indicate that the Division by Zero exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.DZE bit. This bit is only set to 1 to indicate an exception if FPCR.DZE is 0, or if trapping software sets it.

IOC, bit [0]

Invalid Operation cumulative exception bit. This bit is set to 1 to indicate that the Invalid Operation exception has occurred since 0 was last written to this bit.

How scalar and Advanced SIMD floating-point instructions update this bit depends on the value of the FPCR.IOE bit. This bit is only set to 1 to indicate an exception if FPCR.IOE is 0, or if trapping software sets it.

Accessing the FPSR

To access the FPSR:

```
MRS <Xt>, FPSR ; Read FPSR into Xt
MSR FPSR, <Xt> ; Write Xt to FPSR
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0100	001

C5.3.10 NZCV, Condition Flags

The NZCV characteristics are:

Purpose

Allows access to the condition flags.

This register is part of the Process state registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
RW	RW	RW	RW	RW	RW

Configurations

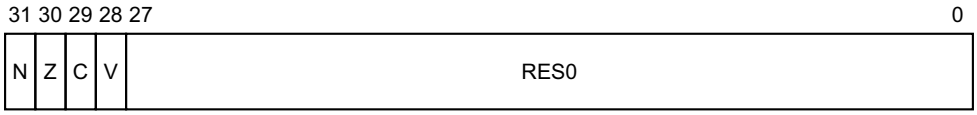
There are no configuration notes.

Attributes

NZCV is a 32-bit register.

Field descriptions

The NZCV bit assignments are:



N, bit [31]

Negative condition flag. Set to bit[31] of the result of the last flag-setting instruction. If the result is regarded as a two's complement signed integer, then the processor sets N to 1 if the result was negative, and sets N to 0 if it was positive or zero.

Z, bit [30]

Zero condition flag. Set to 1 if the result of the last flag-setting instruction was zero, and to 0 otherwise. A result of zero often indicates an equal result from a comparison.

C, bit [29]

Carry condition flag. Set to 1 if the last flag-setting instruction resulted in a carry condition, for example an unsigned overflow on an addition.

V, bit [28]

Overflow condition flag. Set to 1 if the last flag-setting instruction resulted in an overflow condition, for example a signed overflow on an addition.

Bits [27:0]

Reserved, RES0.

Accessing the NZCV

To access the NZCV:

```
MRS <Xt>, NZCV ; Read NZCV into Xt
MSR NZCV, <Xt> ; Write Xt to NZCV
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	011	0100	0010	000

C5.3.11 SP_EL0, Stack Pointer (EL0)

The SP_EL0 characteristics are:

Purpose

Holds the stack pointer if SPSel.SP is 0, or the stack pointer for EL0 if SPSel.SP is 1.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

This register is also accessible at EL0 as the current stack pointer, and at any exception level as the current stack pointer when SPSel.SP is 0.

If SPSel.SP is 0 (the stack pointer selected is SP_EL0) then any access to SP_EL0 using the MSR or MRS instructions is UNDEFINED.

Configurations

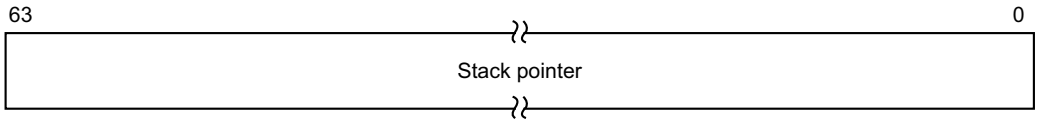
There are no configuration notes.

Attributes

SP_EL0 is a 64-bit register.

Field descriptions

The SP_EL0 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL0

To access the SP_EL0:

```
MRS <Xt>, SP_EL0 ; Read SP_EL0 into Xt
MSR SP_EL0, <Xt> ; Write Xt to SP_EL0
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0001	000

C5.3.12 SP_EL1, Stack Pointer (EL1)

The SP_EL1 characteristics are:

Purpose

Holds the stack pointer for EL1 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

This register is also accessible at EL1 as the current stack pointer when SPSel.SP is 1.

Configurations

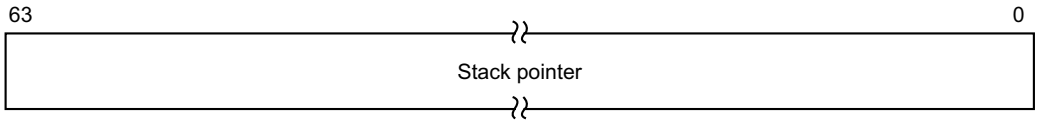
There are no configuration notes.

Attributes

SP_EL1 is a 64-bit register.

Field descriptions

The SP_EL1 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL1

To access the SP_EL1:

```
MRS <Xt>, SP_EL1 ; Read SP_EL1 into Xt
MSR SP_EL1, <Xt> ; Write Xt to SP_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0001	000

C5.3.13 SP_EL2, Stack Pointer (EL2)

The SP_EL2 characteristics are:

Purpose

Holds the stack pointer for EL2 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

This register is also accessible at EL2 as the current stack pointer when SPSel.SP is 1.

Configurations

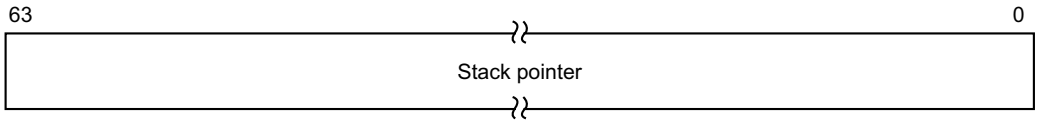
There are no configuration notes.

Attributes

SP_EL2 is a 64-bit register.

Field descriptions

The SP_EL2 bit assignments are:



Bits [63:0]

Stack pointer.

Accessing the SP_EL2

To access the SP_EL2:

```
MRS <Xt>, SP_EL2 ; Read SP_EL2 into Xt
MSR SP_EL2, <Xt> ; Write Xt to SP_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0100	0001	000

C5.3.14 SP_EL3, Stack Pointer (EL3)

The SP_EL3 characteristics are:

Purpose

Holds the stack pointer for EL3 if SPSel.SP is 1 (the stack pointer selected is SP_ELx).

This register is part of the Special purpose registers functional group.

Usage constraints

Accessing this register depends on which field is being accessed; see the register field descriptions for the states that they are accessible in.

This register is only accessible at EL3 as the current stack pointer when SPSel.SP is 1.

Configurations

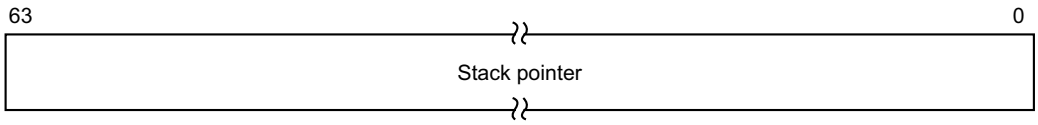
There are no configuration notes.

Attributes

SP_EL3 is a 64-bit register.

Field descriptions

The SP_EL3 bit assignments are:



Bits [63:0]

Stack pointer.

C5.3.15 SPSel, Stack Pointer Select

The SPSel characteristics are:

Purpose

Allows the Stack Pointer to be selected between SP_EL0 and SP_ELx.

This register is part of the Process state registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

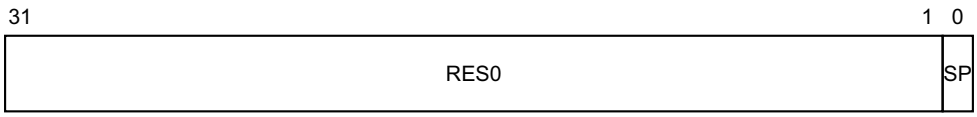
There are no configuration notes.

Attributes

SPSel is a 32-bit register.

Field descriptions

The SPSel bit assignments are:



Bits [31:1]

Reserved, RES0.

SP, bit [0]

Stack pointer to use. Possible values of this bit are:

0 Use SP_EL0 at all exception levels.

1 Use SP_ELx for exception level ELx.

Resets to 1.

Accessing the SPSel

To access the SPSel:

```
MRS <Xt>, SPSel ; Read SPSel into Xt
MSR SPSel, <Xt> ; Write Xt to SPSel
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0010	000

C5.3.16 SPSR_abt, Saved Program Status Register (Abort mode)

The SPSR_abt characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Abort mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SPSR_abt is architecturally mapped to AArch32 register SPSR_abt.

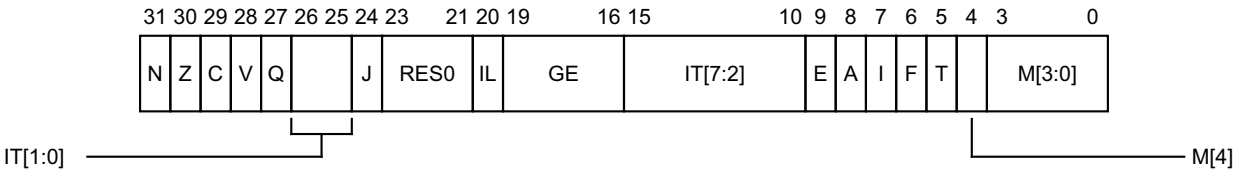
If EL1 does not support execution in AArch32, this register is RES0.

Attributes

SPSR_abt is a 32-bit register.

Field descriptions

The SPSR_abt bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Abort mode, and copied to CPSR.N on executing an exception return operation in Abort mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Abort mode, and copied to CPSR.Z on executing an exception return operation in Abort mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Abort mode, and copied to CPSR.C on executing an exception return operation in Abort mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Abort mode, and copied to CPSR.V on executing an exception return operation in Abort mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_abt

To access the SPSR_abt:

```
MRS <Xt>, SPSR_abt ; Read SPSR_abt into Xt
MSR SPSR_abt, <Xt> ; Write Xt to SPSR_abt
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0011	001

C5.3.17 SPSR_EL1, Saved Program Status Register (EL1)

The SPSR_EL1 characteristics are:

Purpose

Holds the saved processor state when an exception is taken to EL1.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	RW	RW	RW	RW	RW

Configurations

SPSR_EL1 is architecturally mapped to AArch32 register SPSR_svc.

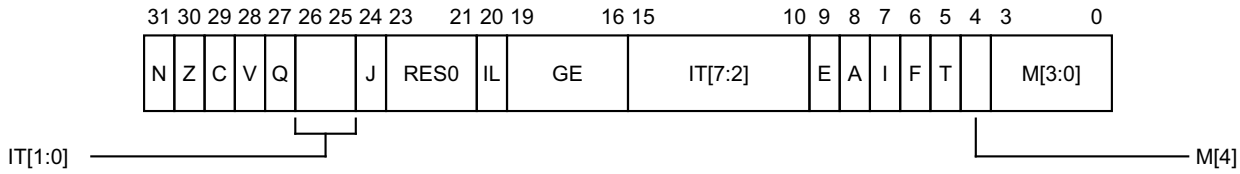
Attributes

SPSR_EL1 is a 32-bit register.

Field descriptions

The SPSR_EL1 bit assignments are:

When exception taken from AArch32:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Supervisor mode, and copied to CPSR.N on executing an exception return operation in Supervisor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Supervisor mode, and copied to CPSR.Z on executing an exception return operation in Supervisor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Supervisor mode, and copied to CPSR.C on executing an exception return operation in Supervisor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Supervisor mode, and copied to CPSR.V on executing an exception return operation in Supervisor mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

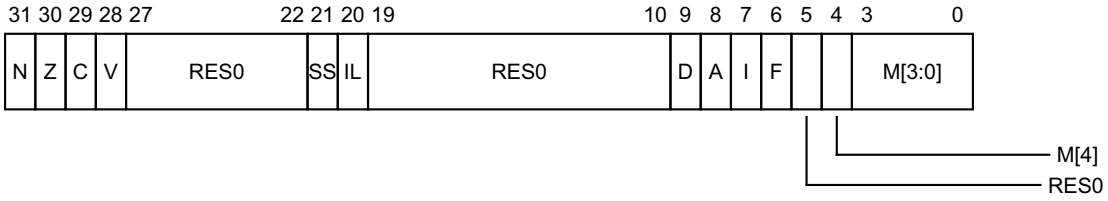
M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0111`	Abort
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

When exception taken from AArch64:



N, bit [31]

Set to the value of the N condition flag on taking an exception to EL1, and copied to the N condition flag on executing an exception return operation in EL1.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL1, and copied to the Z condition flag on executing an exception return operation in EL1.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL1, and copied to the C condition flag on executing an exception return operation in EL1.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL1, and copied to the V condition flag on executing an exception return operation in EL1.

Bits [27:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when an exception was taken.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are not masked.

`1` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are masked.

When the target exception level of the debug exception is not than the current exception level, the exception is not masked by this bit.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch64, the possible values are:

M[3:0]	Mode
0b0000	EL0t
0b0100	EL1t
0b0101	EL1h

Other values are reserved.

For exceptions from AArch64:

- M[3:2] holds the Exception Level.
- M[1] is unused, and returning to an exception level that is using AArch64 with this bit set is treated as an illegal exception return.
- M[0] is used to select the SP:
  - — 0 means the SP is always SP0.
  - — 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL1

To access the SPSR_EL1:

```
MRS <Xt>, SPSR_EL1 ; Read SPSR_EL1 into Xt
MSR SPSR_EL1, <Xt> ; Write Xt to SPSR_EL1
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	000	0100	0000	000

C5.3.18 SPSR_EL2, Saved Program Status Register (EL2)

The SPSR_EL2 characteristics are:

Purpose

Holds the saved processor state when an exception is taken to EL2.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SPSR_EL2 is architecturally mapped to AArch32 register SPSR_hyp.

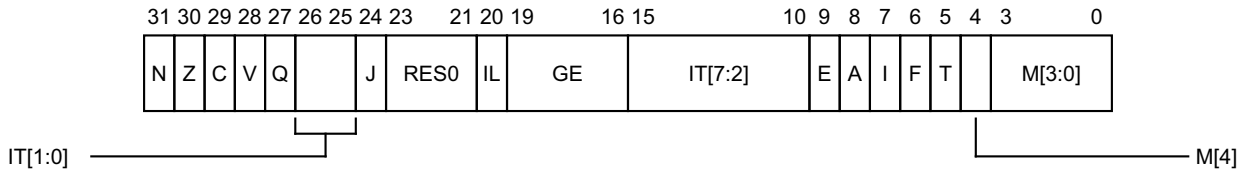
Attributes

SPSR_EL2 is a 32-bit register.

Field descriptions

The SPSR_EL2 bit assignments are:

When exception taken from AArch32:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Hyp mode, and copied to CPSR.N on executing an exception return operation in Hyp mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Hyp mode, and copied to CPSR.Z on executing an exception return operation in Hyp mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Hyp mode, and copied to CPSR.C on executing an exception return operation in Hyp mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Hyp mode, and copied to CPSR.V on executing an exception return operation in Hyp mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

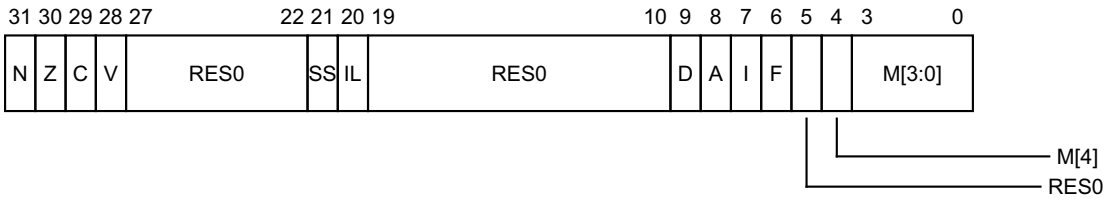
M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

When exception taken from AArch64:



N, bit [31]

Set to the value of the N condition flag on taking an exception to EL2, and copied to the N condition flag on executing an exception return operation in EL2.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL2, and copied to the Z condition flag on executing an exception return operation in EL2.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL2, and copied to the C condition flag on executing an exception return operation in EL2.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL2, and copied to the V condition flag on executing an exception return operation in EL2.

Bits [27:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when an exception was taken.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are not masked.

`1` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are masked.

When the target exception level of the debug exception is not than the current exception level, the exception is not masked by this bit.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch64, the possible values are:

M[3:0]	Mode
0b0000	EL0t
0b0100	EL1t
0b0101	EL1h
0b1000	EL2t
0b1001	EL2h

Other values are reserved.

For exceptions from AArch64:

- M[3:2] holds the Exception Level.
- M[1] is unused, and returning to an exception level that is using AArch64 with this bit set is treated as an illegal exception return.
- M[0] is used to select the SP:
  - — 0 means the SP is always SP0.
  - — 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL2

To access the SPSR_EL2:

```
MRS <Xt>, SPSR_EL2 ; Read SPSR_EL2 into Xt
MSR SPSR_EL2, <Xt> ; Write Xt to SPSR_EL2
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0000	000

C5.3.19 SPSR_EL3, Saved Program Status Register (EL3)

The SPSR_EL3 characteristics are:

Purpose

Holds the saved processor state when an exception is taken to EL3.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	RW	RW

Configurations

SPSR_EL3 can be mapped to AArch32 register SPSR_mon, but this is not architecturally mandated.

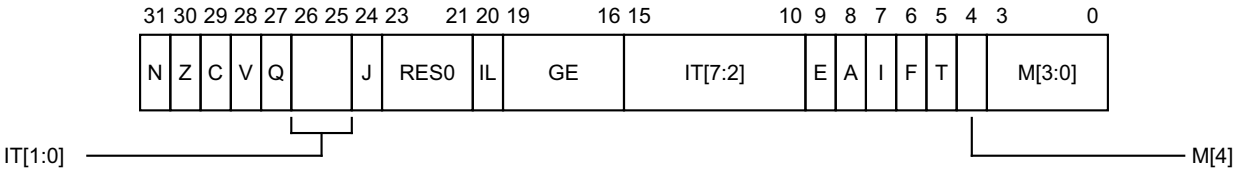
Attributes

SPSR_EL3 is a 32-bit register.

Field descriptions

The SPSR_EL3 bit assignments are:

When exception taken from AArch32:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Monitor mode, and copied to CPSR.N on executing an exception return operation in Monitor mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Monitor mode, and copied to CPSR.Z on executing an exception return operation in Monitor mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Monitor mode, and copied to CPSR.C on executing an exception return operation in Monitor mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Monitor mode, and copied to CPSR.V on executing an exception return operation in Monitor mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

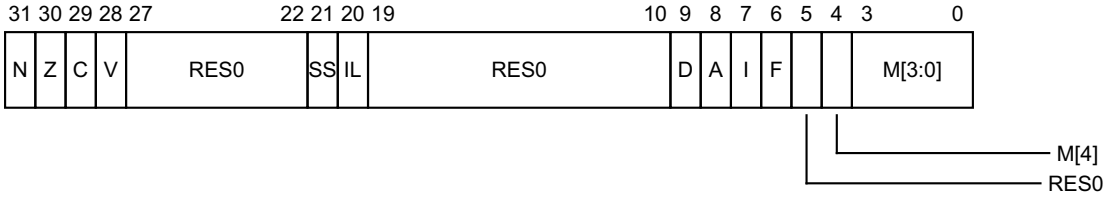
M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

When exception taken from AArch64:



N, bit [31]

Set to the value of the N condition flag on taking an exception to EL3, and copied to the N condition flag on executing an exception return operation in EL3.

Z, bit [30]

Set to the value of the Z condition flag on taking an exception to EL3, and copied to the Z condition flag on executing an exception return operation in EL3.

C, bit [29]

Set to the value of the C condition flag on taking an exception to EL3, and copied to the C condition flag on executing an exception return operation in EL3.

V, bit [28]

Set to the value of the V condition flag on taking an exception to EL3, and copied to the V condition flag on executing an exception return operation in EL3.

Bits [27:22]

Reserved, RES0.

SS, bit [21]

Software step. Indicates whether software step was enabled when an exception was taken.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

Bits [19:10]

Reserved, RES0.

D, bit [9]

Process state D mask. The possible values of this bit are:

`0` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are not masked.

`1` Debug exceptions from Watchpoint, Breakpoint, and Software step debug events targeted at the current exception level are masked.

When the target exception level of the debug exception is not than the current exception level, the exception is not masked by this bit.

A, bit [8]

SError (System Error) mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

Bit [5]

Reserved, RES0.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`0` Exception taken from AArch64.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch64, the possible values are:

M[3:0]	Mode
0b0000	EL0t
0b0100	EL1t
0b0101	EL1h
0b1000	EL2t
0b1001	EL2h
0b1100	EL3t
0b1101	EL3h

Other values are reserved.

For exceptions from AArch64:

- M[3:2] holds the Exception Level.
- M[1] is unused, and returning to an exception level that is using AArch64 with this bit set is treated as an illegal exception return.
- M[0] is used to select the SP:
  - — 0 means the SP is always SP0.
  - — 1 means the exception SP is determined by the EL.

Accessing the SPSR_EL3

To access the SPSR_EL3:

```
MRS <Xt>, SPSR_EL3 ; Read SPSR_EL3 into Xt
MSR SPSR_EL3, <Xt> ; Write Xt to SPSR_EL3
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	110	0100	0000	000

C5.3.20 SPSR_fiq, Saved Program Status Register (FIQ mode)

The SPSR_fiq characteristics are:

Purpose

Holds the saved processor state when an exception is taken to FIQ mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SPSR_fiq is architecturally mapped to AArch32 register SPSR_fiq.

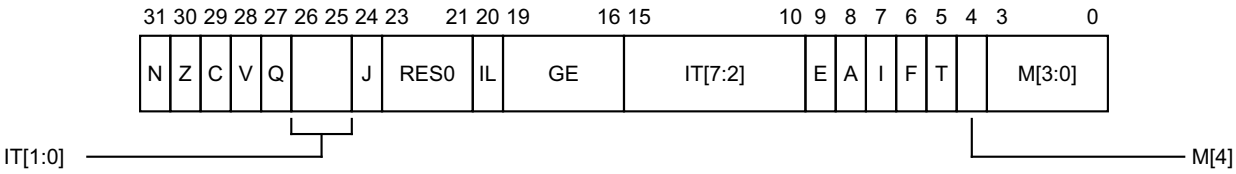
If EL1 does not support execution in AArch32, this register is RES0.

Attributes

SPSR_fiq is a 32-bit register.

Field descriptions

The SPSR_fiq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to FIQ mode, and copied to CPSR.N on executing an exception return operation in FIQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to FIQ mode, and copied to CPSR.Z on executing an exception return operation in FIQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to FIQ mode, and copied to CPSR.C on executing an exception return operation in FIQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to FIQ mode, and copied to CPSR.V on executing an exception return operation in FIQ mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

0 Exception not masked.

1 Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

0 Taken from A32 state.

1 Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

1 Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_fiq

To access the SPSR_fiq:

```
MRS <Xt>, SPSR_fiq ; Read SPSR_fiq into Xt
MSR SPSR_fiq, <Xt> ; Write Xt to SPSR_fiq
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0011	011

C5.3.21 SPSR_irq, Saved Program Status Register (IRQ mode)

The SPSR_irq characteristics are:

Purpose

Holds the saved processor state when an exception is taken to IRQ mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SPSR_irq is architecturally mapped to AArch32 register SPSR_irq.

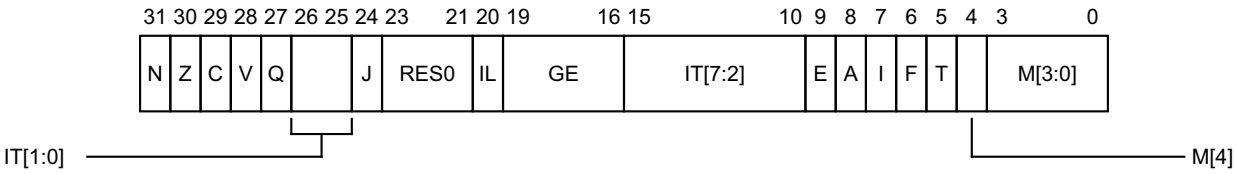
If EL1 does not support execution in AArch32, this register is RES0.

Attributes

SPSR_irq is a 32-bit register.

Field descriptions

The SPSR_irq bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to IRQ mode, and copied to CPSR.N on executing an exception return operation in IRQ mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to IRQ mode, and copied to CPSR.Z on executing an exception return operation in IRQ mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to IRQ mode, and copied to CPSR.C on executing an exception return operation in IRQ mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to IRQ mode, and copied to CPSR.V on executing an exception return operation in IRQ mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
`0b0000`	User
`0b0001`	FIQ
`0b0010`	IRQ
`0b0011`	Supervisor
`0b0110`	Monitor
`0b0111`	Abort
`0b1010`	Hyp
`0b1011`	Undefined
`0b1111`	System

Other values are reserved.

Accessing the SPSR_irq

To access the SPSR_irq:

```
MRS <Xt>, SPSR_irq ; Read SPSR_irq into Xt
MSR SPSR_irq, <Xt> ; Write Xt to SPSR_irq
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0011	000

C5.3.22 SPSR_und, Saved Program Status Register (Undefined mode)

The SPSR_und characteristics are:

Purpose

Holds the saved processor state when an exception is taken to Undefined mode.

This register is part of the Special purpose registers functional group.

Usage constraints

This register is accessible as shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	RW	RW	RW

Configurations

SPSR_und is architecturally mapped to AArch32 register SPSR_und.

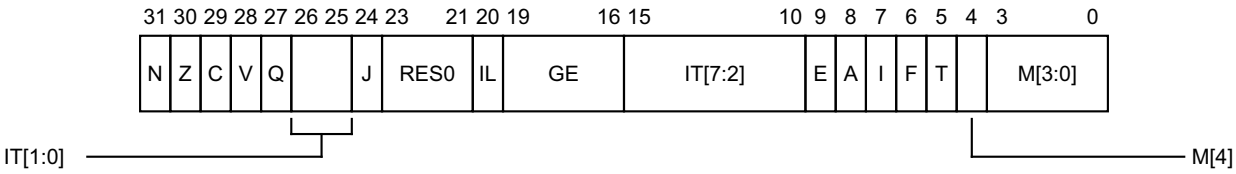
If EL1 does not support execution in AArch32, this register is RES0.

Attributes

SPSR_und is a 32-bit register.

Field descriptions

The SPSR_und bit assignments are:



N, bit [31]

Set to the value of CPSR.N on taking an exception to Undefined mode, and copied to CPSR.N on executing an exception return operation in Undefined mode.

Z, bit [30]

Set to the value of CPSR.Z on taking an exception to Undefined mode, and copied to CPSR.Z on executing an exception return operation in Undefined mode.

C, bit [29]

Set to the value of CPSR.C on taking an exception to Undefined mode, and copied to CPSR.C on executing an exception return operation in Undefined mode.

V, bit [28]

Set to the value of CPSR.V on taking an exception to Undefined mode, and copied to CPSR.V on executing an exception return operation in Undefined mode.

Q, bit [27]

Cumulative saturation bit. Set to 1 to indicate that overflow or saturation occurred in some instructions.

IT[1:0], bits [26:25]

If-Then Execution State bits for the T32 IT (If-Then) instruction. See IT[7:2] for explanation of this field.

J, bit [24]

RES0.

In previous versions of the architecture, the {J, T} bits determined the AArch32 Instruction set state. ARMv8 does not support either Jazelle state or T32EE state, and the T bit determines the Instruction set state.

Bits [23:21]

Reserved, RES0.

IL, bit [20]

Illegal Execution State bit. Shows the value of PSTATE.IL immediately before the exception was taken.

GE, bits [19:16]

Greater than or Equal flags, for parallel addition and subtraction.

IT[7:2], bits [15:10]

If-Then Execution State bits for the T32 IT (If-Then) instruction. This field must be interpreted in two parts.

- IT[7:5] holds the base condition for the IT block. The base condition is the top 3 bits of the condition code specified by the first condition field of the IT instruction.
- IT[4:0] encodes the size of the IT block, which is the number of instructions that are to be conditionally executed, by the position of the least significant 1 in this field. It also encodes the value of the least significant bit of the condition code for each instruction in the block.

The IT field is `0b00000000` when no IT block is active.

E, bit [9]

Endianness Execution State bit. Controls the load and store endianness for data accesses:

`0` Little-endian operation

`1` Big-endian operation.

Instruction fetches ignore this bit.

When the reset value of the SCTLR.EE bit is defined by a configuration input signal, that value also applies to the CPSR.E bit on reset, and therefore applies to software execution from reset.

If an implementation does not provide Big-endian support, this bit is RES0. If it does not provide Little-endian support, this bit is RES1.

If an implementation provides Big-endian support but only at EL0, this bit is RES0 for an exception return to any exception level other than EL0.

Likewise, if it provides Little-endian support only at EL0, this bit is RES1 for an exception return to any exception level other than EL0.

A, bit [8]

Asynchronous data abort mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

I, bit [7]

IRQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

F, bit [6]

FIQ mask bit. The possible values of this bit are:

`0` Exception not masked.

`1` Exception masked.

T, bit [5]

T32 Instruction set state bit. Determines the AArch32 instruction set state that the exception was taken from. Possible values of this bit are:

`0` Taken from A32 state.

`1` Taken from T32 state.

M[4], bit [4]

Execution state that the exception was taken from. Possible values of this bit are:

`1` Exception taken from AArch32.

M[3:0], bits [3:0]

Mode that an exception was taken from. For exceptions taken from AArch32, the possible values are:

M[3:0]	Mode
0b0000	User
0b0001	FIQ
0b0010	IRQ
0b0011	Supervisor
0b0110	Monitor
0b0111	Abort
0b1010	Hyp
0b1011	Undefined
0b1111	System

Other values are reserved.

Accessing the SPSR_und

To access the SPSR_und:

```
MRS <Xt>, SPSR_und ; Read SPSR_und into Xt
MSR SPSR_und, <Xt> ; Write Xt to SPSR_und
```

Register access is encoded as follows:

op0	op1	CRn	CRm	op2
11	100	0100	0011	010

C5.4 A64 system instructions for cache maintenance

This section lists the A64 cache maintenance system instructions:

C5.4.1 DC CISW, Data or unified Cache line Clean and Invalidate by Set/Way

The DC CISW characteristics are:

Purpose

Clean and Invalidate data cache by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

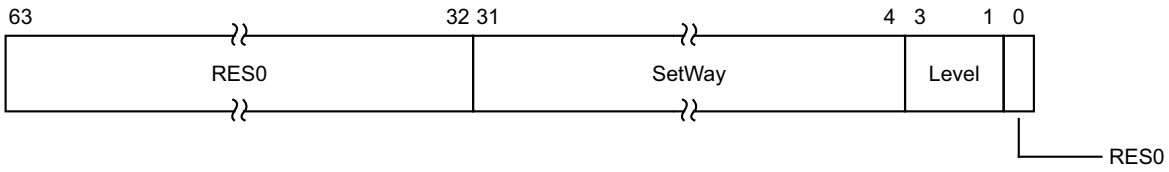
DC CISW performs the same function as AArch32 operation DCCISW.

Attributes

DC CISW is a 64-bit system operation.

Field descriptions

The DC CISW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DC CISW operation

To perform the DC CISW operation:

```
DC CISW, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1110	010

C5.4.2 DC CIVAC, Data or unified Cache line Clean and Invalidate by VA to PoC

The DC CIVAC characteristics are:

Purpose

Clean and Invalidate data cache by address to Point of Coherency.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

EL0 access is enabled when SCTLR_EL1.UCI is set to 1. When it is set to 0, this operation is UNDEFINED at EL0.

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

Configurations

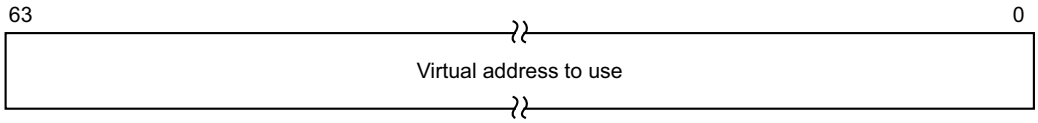
DC CIVAC performs the same function as AArch32 operation DCCIMVAC.

Attributes

DC CIVAC is a 64-bit system operation.

Field descriptions

The DC CIVAC input value bit assignments are:



Bits [63:0]

Virtual address to use.

Performing the DC CIVAC operation

To perform the DC CIVAC operation:

```
DC CIVAC, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	011	0111	1110	001

C5.4.3 DC CSW, Data or unified Cache line Clean by Set/Way

The DC CSW characteristics are:

Purpose

Clean data cache by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

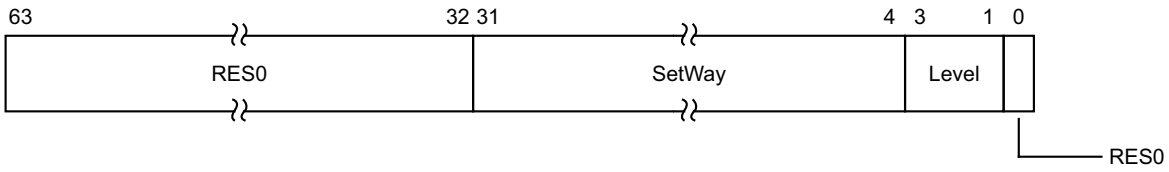
DC CSW performs the same function as AArch32 operation DCCSW.

Attributes

DC CSW is a 64-bit system operation.

Field descriptions

The DC CSW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DC CSW operation

To perform the DC CSW operation:

```
DC CSW, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1010	010

C5.4.4 DC CVAC, Data or unified Cache line Clean by VA to PoC

The DC CVAC characteristics are:

Purpose

Clean data cache by address to Point of Coherency.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

EL0 access is enabled when SCTLR_EL1.UCI is set to 1. When it is set to 0, this operation is UNDEFINED at EL0.

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

Configurations

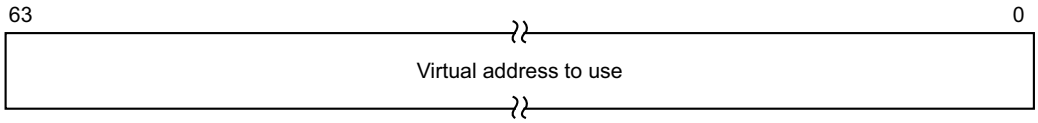
DC CVAC performs the same function as AArch32 operation DCCMVAC.

Attributes

DC CVAC is a 64-bit system operation.

Field descriptions

The DC CVAC input value bit assignments are:



Bits [63:0]

Virtual address to use.

Performing the DC CVAC operation

To perform the DC CVAC operation:

```
DC CVAC, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	011	0111	1010	001

C5.4.5 DC CVAU, Data or unified Cache line Clean by VA to PoU

The DC CVAU characteristics are:

Purpose

Clean data cache by address to Point of Unification.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

EL0 access is enabled when SCTLR_EL1.UCI is set to 1. When it is set to 0, this operation is UNDEFINED at EL0.

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

Configurations

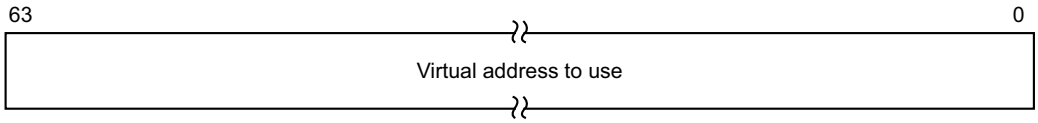
DC CVAU performs the same function as AArch32 operation DCCMVAU.

Attributes

DC CVAU is a 64-bit system operation.

Field descriptions

The DC CVAU input value bit assignments are:



Bits [63:0]

Virtual address to use.

Performing the DC CVAU operation

To perform the DC CVAU operation:

```
DC CVAU, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	011	0111	1011	001

C5.4.6 DC ISW, Data or unified Cache line Invalidate by Set/Way

The DC ISW characteristics are:

Purpose

Invalidate data cache by set/way.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

At EL1, this operation must be performed as DC CISW if all of the following apply:

- EL2 is implemented
- HCR_EL2.VM is set to 1
- SCR_EL3.NS is set to 1 or EL3 is not implemented.

Configurations

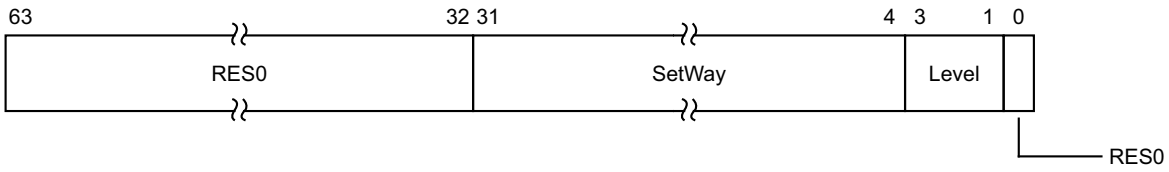
DC ISW performs the same function as AArch32 operation DCISW.

Attributes

DC ISW is a 64-bit system operation.

Field descriptions

The DC ISW input value bit assignments are:



Bits [63:32]

Reserved, RES0.

SetWay, bits [31:4]

Contains two fields:

- Way, bits[31:32-A], the number of the way to operate on.
- Set, bits[B-1:L], the number of the set to operate on.

Bits[L-1:4] are RES0.

A = Log_2(ASSOCIATIVITY), L = Log_2(LINELEN), B = (L + S), S = Log_2(NSETS).

ASSOCIATIVITY, LINELEN (line length, in bytes), and NSETS (number of sets) have their usual meanings and are the values for the cache level being operated on. The values of A and S are rounded up to the next integer.

Level, bits [3:1]

Cache level to operate on, minus 1. For example, this field is 0 for operations on L1 cache, or 1 for operations on L2 cache.

Bit [0]

Reserved, RES0.

Performing the DC ISW operation

To perform the DC ISW operation:

```
DC ISW, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	0110	010

C5.4.7 DC IVAC, Data or unified Cache line Invalidate by VA to PoC

The DC IVAC characteristics are:

Purpose

Invalidate instruction cache by address to Point of Coherency.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

This operation requires write access permission to the VA, otherwise it causes a Permission Fault.

At EL1, this operation must be performed as DC CIVAC if all of the following apply:

- EL2 is implemented.
- HCR_EL2.VM is set to 1.
- SCR_EL3.NS is set to 1 or EL3 is not implemented.

Configurations

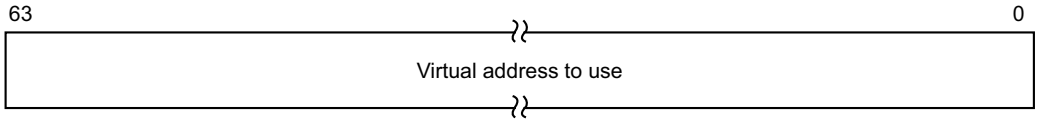
DC IVAC performs the same function as AArch32 operation DCIMVAC.

Attributes

DC IVAC is a 64-bit system operation.

Field descriptions

The DC IVAC input value bit assignments are:



Bits [63:0]

Virtual address to use.

Performing the DC IVAC operation

To perform the DC IVAC operation:

```
DC IVAC, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	0110	001

C5.4.8 DC ZVA, Data Cache Zero by VA

The DC ZVA characteristics are:

Purpose

Zero data cache by address. Zeroes a naturally aligned block of N bytes, where the size of N is identified in DCZID_EL0.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

There are two control bits associated with this instruction: SCTLR_EL1.DZE and HCR_EL2.TDZ.

- If execution at EL0 is disabled by the SCTLR_EL1.DZE bit being set to 0, the instruction is UNDEFINED at EL0.
- In the Non-secure state, HCR_EL2.TDZ controls whether the instruction executes at EL0 or EL1, or traps to EL2.

When UNDEFINED, the instruction always takes the EL1 UNDEFINED exception.

When the instruction is executed, it can generate memory faults or watchpoints which are prioritized in the same way as other memory related faults or watchpoints. If a synchronous data abort fault or a watchpoint is generated, the CM bit in the syndrome field is not set.

If the memory region being zeroed is any type of Device memory, these instructions give an alignment fault which is prioritized in the same way as other alignment faults that are determined by the memory type.

This instruction applies to Normal memory regardless of cacheability attributes.

The instruction behaves as a set of Stores to each byte within the block being accessed, and so it:

- Will cause a Permission Fault if the translation system does not permit writes to the locations.
- Requires the same considerations for ordering and the management of coherency as any other store instructions.

Configurations

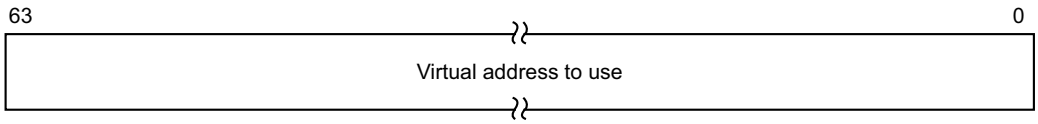
There are no configuration notes.

Attributes

DC ZVA is a 64-bit system operation.

Field descriptions

The DC ZVA input value bit assignments are:



Bits [63:0]

Virtual address to use. There is no alignment restriction on the address within the block of N bytes that is used.

Performing the DC ZVA operation

To perform the DC ZVA operation:

```
DC ZVA, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	011	0111	0100	001

C5.4.9 IC IALLU, Instruction Cache Invalidate All to PoU

The IC IALLU characteristics are:

Purpose

Invalidate all instruction caches to Point of Unification.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

IC IALLU performs the same function as AArch32 operation ICIALLU.

Attributes

IC IALLU is a 64-bit system operation.

Field descriptions

The IC IALLU operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the IC IALLU operation

To perform the IC IALLU operation:

```
IC IALLU
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	0101	000

C5.4.10 IC IALLUIS, Instruction Cache Invalidate All to PoU, Inner Shareable

The IC IALLUIS characteristics are:

Purpose

Invalidate all instruction caches in Inner Shareable domain to Point of Unification.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

IC IALLUIS performs the same function as AArch32 operation ICIALLUIS.

Attributes

IC IALLUIS is a 64-bit system operation.

Field descriptions

The IC IALLUIS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the IC IALLUIS operation

To perform the IC IALLUIS operation:

```
IC IALLUIS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	0001	000

C5.4.11 IC IVAU, Instruction Cache line Invalidate by VA to PoU

The IC IVAU characteristics are:

Purpose

Invalidate instruction cache by address to Point of Unification.

This register is part of the Cache maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
Config-WO	WO	WO	WO	WO	WO

EL0 access is enabled when SCTLR_EL1.UCI is set to 1. When it is set to 0, this operation is UNDEFINED at EL0.

If EL0 access is enabled, this operation is available at EL0 when the VA has read access permission, otherwise it causes a Permission Fault.

Configurations

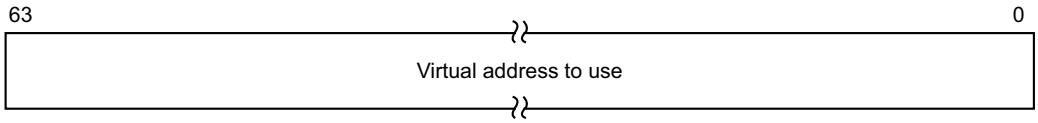
IC IVAU performs the same function as AArch32 operation ICIMVAU.

Attributes

IC IVAU is a 64-bit system operation.

Field descriptions

The IC IVAU input value bit assignments are:



Bits [63:0]

Virtual address to use.

Performing the IC IVAU operation

To perform the IC IVAU operation:

```
IC IVAU, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	011	0111	0101	001

C5.5 A64 system instructions for address translation

This section lists the A64 address translation system instructions.

C5.5.1 AT S12E0R, Address Translate Stages 1 and 2 EL0 Read

The AT S12E0R characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for EL0, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E0R.

Configurations

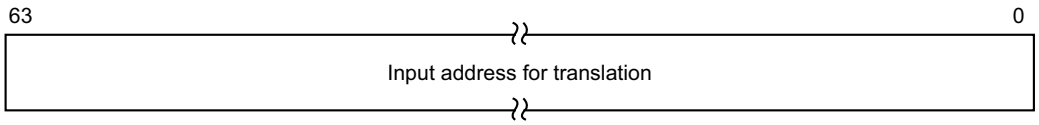
There are no configuration notes.

Attributes

AT S12E0R is a 64-bit system operation.

Field descriptions

The AT S12E0R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S12E0R operation

To perform the AT S12E0R operation:

```
AT S12E0R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	110

C5.5.2 AT S12E0W, Address Translate Stages 1 and 2 EL0 Write

The AT S12E0W characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for EL0, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E0W.

Configurations

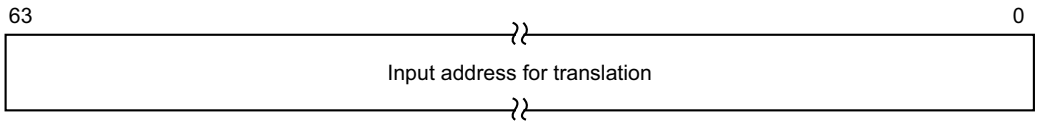
There are no configuration notes.

Attributes

AT S12E0W is a 64-bit system operation.

Field descriptions

The AT S12E0W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S12E0W operation

To perform the AT S12E0W operation:

```
AT S12E0W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	111

C5.5.3 AT S12E1R, Address Translate Stages 1 and 2 EL1 Read

The AT S12E1R characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for EL1, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E1R.

Configurations

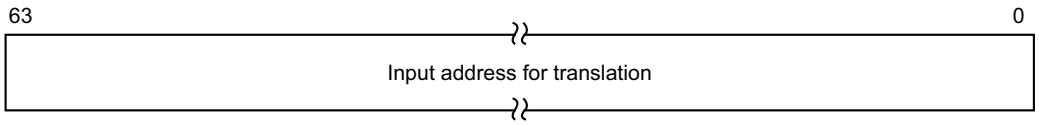
There are no configuration notes.

Attributes

AT S12E1R is a 64-bit system operation.

Field descriptions

The AT S12E1R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S12E1R operation

To perform the AT S12E1R operation:

```
AT S12E1R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	100

C5.5.4 AT S12E1W, Address Translate Stages 1 and 2 EL1 Write

The AT S12E1W characteristics are:

Purpose

Performs stage 1 and 2 address translations as defined for EL1, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL2 does not exist, or stage 2 translation is disabled, this operation executes as AT S1E1W.

Configurations

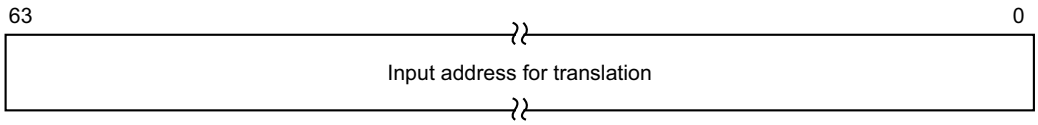
There are no configuration notes.

Attributes

AT S12E1W is a 64-bit system operation.

Field descriptions

The AT S12E1W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S12E1W operation

To perform the AT S12E1W operation:

```
AT S12E1W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	101

C5.5.5 AT S1E0R, Address Translate Stage 1 EL0 Read

The AT S1E0R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL0, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

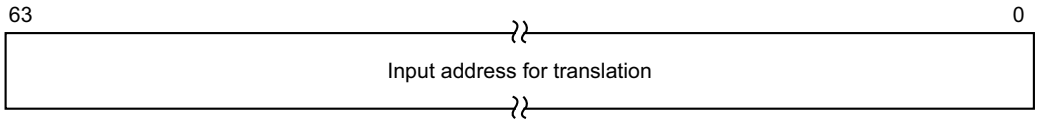
There are no configuration notes.

Attributes

AT S1E0R is a 64-bit system operation.

Field descriptions

The AT S1E0R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E0R operation

To perform the AT S1E0R operation:

```
AT S1E0R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1000	010

C5.5.6 AT S1E0W, Address Translate Stage 1 EL0 Write

The AT S1E0W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL0, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

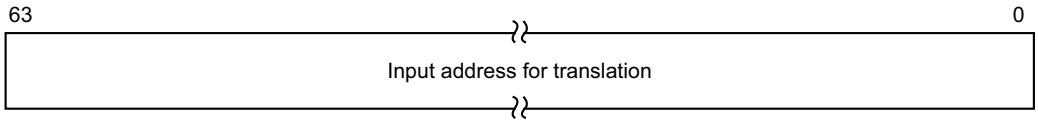
There are no configuration notes.

Attributes

AT S1E0W is a 64-bit system operation.

Field descriptions

The AT S1E0W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E0W operation

To perform the AT S1E0W operation:

```
AT S1E0W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1000	011

C5.5.7 AT S1E1R, Address Translate Stage 1 EL1 Read

The AT S1E1R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL1, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

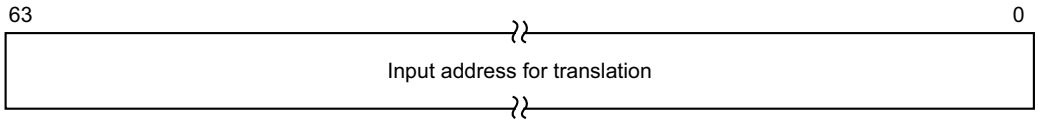
There are no configuration notes.

Attributes

AT S1E1R is a 64-bit system operation.

Field descriptions

The AT S1E1R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E1R operation

To perform the AT S1E1R operation:

```
AT S1E1R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1000	000

C5.5.8 AT S1E1W, Address Translate Stage 1 EL1 Write

The AT S1E1W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL1, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

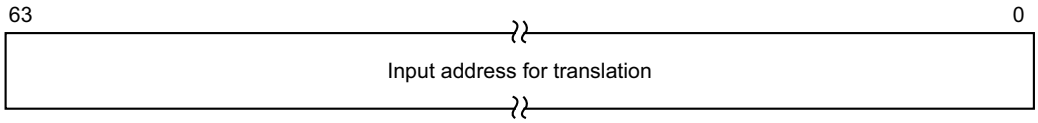
There are no configuration notes.

Attributes

AT S1E1W is a 64-bit system operation.

Field descriptions

The AT S1E1W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E1W operation

To perform the AT S1E1W operation:

```
AT S1E1W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	0111	1000	001

C5.5.9 AT S1E2R, Address Translate Stage 1 EL2 Read

The AT S1E2R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

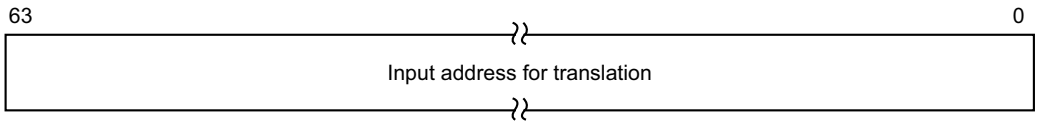
There are no configuration notes.

Attributes

AT S1E2R is a 64-bit system operation.

Field descriptions

The AT S1E2R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E2R operation

To perform the AT S1E2R operation:

```
AT S1E2R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	000

C5.5.10 AT S1E2W, Address Translate Stage 1 EL2 Write

The AT S1E2W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL2, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

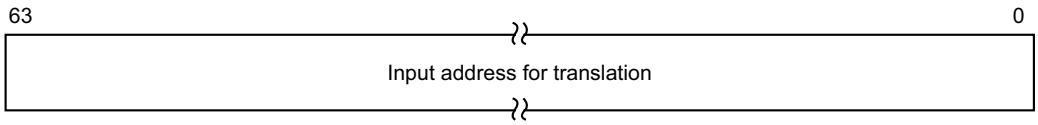
There are no configuration notes.

Attributes

AT S1E2W is a 64-bit system operation.

Field descriptions

The AT S1E2W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E2W operation

To perform the AT S1E2W operation:

```
AT S1E2W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	0111	1000	001

C5.5.11 AT S1E3R, Address Translate Stage 1 EL3 Read

The AT S1E3R characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if reading from the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

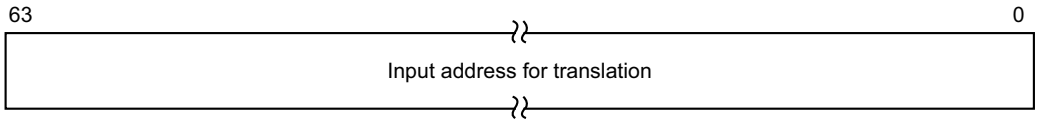
There are no configuration notes.

Attributes

AT S1E3R is a 64-bit system operation.

Field descriptions

The AT S1E3R input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E3R operation

To perform the AT S1E3R operation:

```
AT S1E3R, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	0111	1000	000

C5.5.12 AT S1E3W, Address Translate Stage 1 EL3 Write

The AT S1E3W characteristics are:

Purpose

Performs stage 1 address translation as defined for EL3, with permissions as if writing to the given virtual address.

This register is part of the Address translation instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

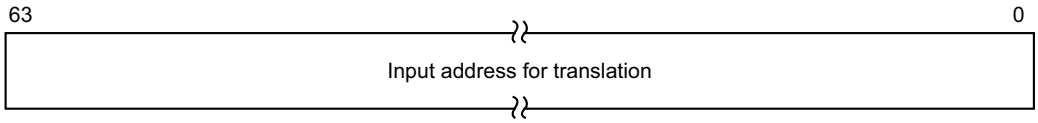
There are no configuration notes.

Attributes

AT S1E3W is a 64-bit system operation.

Field descriptions

The AT S1E3W input value bit assignments are:



Bits [63:0]

Input address for translation. The resulting address can be read from the PAR_EL1.

If the address translation instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then VA[63:32] is RES0.

Performing the AT S1E3W operation

To perform the AT S1E3W operation:

```
AT S1E3W, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	0111	1000	001

C5.6 A64 system instructions for TLB maintenance

This section lists the A64 TLB maintenance system instructions.

C5.6.1 TLBI ALLE1, TLB Invalidate All, EL1

The TLBI ALLE1 characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1 is a 64-bit system operation.

Field descriptions

The TLBI ALLE1 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE1 operation

To perform the TLBI ALLE1 operation:

```
TLBI ALLE1
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0111	100

C5.6.2 TLBI ALLE1IS, TLB Invalidate All, EL1, Inner Shareable

The TLBI ALLE1IS characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE1IS is a 64-bit system operation.

Field descriptions

The TLBI ALLE1IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE1IS operation

To perform the TLBI ALLE1IS operation:

```
TLBI ALLE1IS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0011	100

C5.6.3 TLBI ALLE2, TLB Invalidate All, EL2

The TLBI ALLE2 characteristics are:

Purpose

Invalidate all EL2 regime stage 1 TLB entries.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2 is a 64-bit system operation.

Field descriptions

The TLBI ALLE2 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE2 operation

To perform the TLBI ALLE2 operation:

```
TLBI ALLE2
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0111	000

C5.6.4 TLBI ALLE2IS, TLB Invalidate All, EL2, Inner Shareable

The TLBI ALLE2IS characteristics are:

Purpose

Invalidate all EL2 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

There are no configuration notes.

Attributes

TLBI ALLE2IS is a 64-bit system operation.

Field descriptions

The TLBI ALLE2IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE2IS operation

To perform the TLBI ALLE2IS operation:

```
TLBI ALLE2IS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0011	000

C5.6.5 TLBI ALLE3, TLB Invalidate All, EL3

The TLBI ALLE3 characteristics are:

Purpose

Invalidate all EL3 regime stage 1 TLB entries.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

There are no configuration notes.

Attributes

TLBI ALLE3 is a 64-bit system operation.

Field descriptions

The TLBI ALLE3 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE3 operation

To perform the TLBI ALLE3 operation:

```
TLBI ALLE3
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0111	000

C5.6.6 TLBI ALLE3IS, TLB Invalidate All, EL3, Inner Shareable

The TLBI ALLE3IS characteristics are:

Purpose

Invalidate all EL3 regime stage 1 TLB entries on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

There are no configuration notes.

Attributes

TLBI ALLE3IS is a 64-bit system operation.

Field descriptions

The TLBI ALLE3IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI ALLE3IS operation

To perform the TLBI ALLE3IS operation:

```
TLBI ALLE3IS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0011	000

C5.6.7 TLBI ASIDE1, TLB Invalidate by ASID, EL1

The TLBI ASIDE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

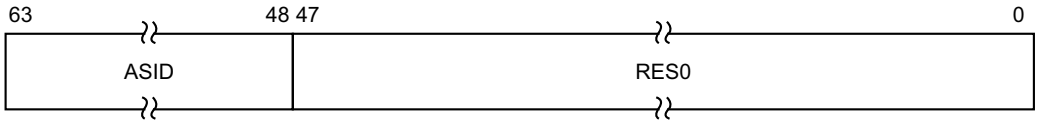
There are no configuration notes.

Attributes

TLBI ASIDE1 is a 64-bit system operation.

Field descriptions

The TLBI ASIDE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:0]

Reserved, RES0.

Performing the TLBI ASIDE1 operation

To perform the TLBI ASIDE1 operation:

```
TLBI ASIDE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	010

C5.6.8 TLBI ASIDE1IS, TLB Invalidate by ASID, EL1, Inner Shareable

The TLBI ASIDE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given ASID and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

Configurations

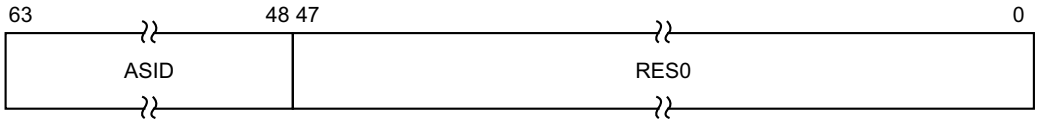
There are no configuration notes.

Attributes

TLBI ASIDE1IS is a 64-bit system operation.

Field descriptions

The TLBI ASIDE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any appropriate TLB entries that match the ASID values will be affected by this operation.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:0]

Reserved, RES0.

Performing the TLBI ASIDE1IS operation

To perform the TLBI ASIDE1IS operation:

```
TLBI ASIDE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	010

C5.6.9 TLBI IPAS2E1, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1

The TLBI IPAS2E1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

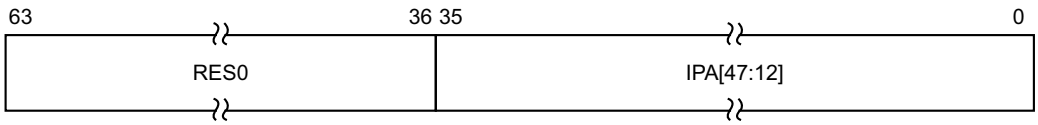
There are no configuration notes.

Attributes

TLBI IPAS2E1 is a 64-bit system operation.

Field descriptions

The TLBI IPAS2E1 input value bit assignments are:



Bits [63:36]

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

Performing the TLBI IPAS2E1 operation

To perform the TLBI IPAS2E1 operation:

```
TLBI IPAS2E1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0100	001

C5.6.10 TLBI IPAS2E1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, EL1, Inner Shareable

The TLBI IPAS2E1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the given IPA and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

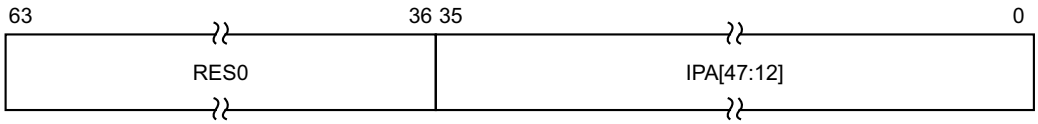
There are no configuration notes.

Attributes

TLBI IPAS2E1IS is a 64-bit system operation.

Field descriptions

The TLBI IPAS2E1IS input value bit assignments are:



Bits [63:36]

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

Performing the TLBI IPAS2E1IS operation

To perform the TLBI IPAS2E1IS operation:

```
TLBI IPAS2E1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0000	001

C5.6.11 TLBI IPAS2LE1, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1

The TLBI IPAS2LE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

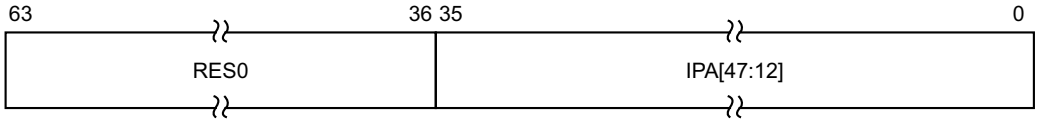
There are no configuration notes.

Attributes

TLBI IPAS2LE1 is a 64-bit system operation.

Field descriptions

The TLBI IPAS2LE1 input value bit assignments are:



Bits [63:36]

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

Performing the TLBI IPAS2LE1 operation

To perform the TLBI IPAS2LE1 operation:

```
TLBI IPAS2LE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0100	101

C5.6.12 TLBI IPAS2LE1IS, TLB Invalidate by Intermediate Physical Address, Stage 2, Last level, EL1, Inner Shareable

The TLBI IPAS2LE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 2 TLB entries for the last level of translation, the given IPA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of:

- the TLB maintenance instructions functional group
- the Virtualization registers functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If SCR_EL3.NS==0, or EL2 is not implemented, this instruction is a NOP.

This instruction must apply to structures that contain only stage 2 translation information, but does not need to apply to structures that contain combined stage 1 and stage 2 translation information.

Configurations

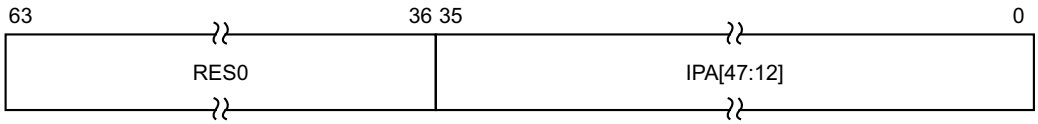
There are no configuration notes.

Attributes

TLBI IPAS2LE1IS is a 64-bit system operation.

Field descriptions

The TLBI IPAS2LE1IS input value bit assignments are:



Bits [63:36]

Reserved, RES0.

IPA[47:12], bits [35:0]

Bits[47:12] of the intermediate physical address to match.

Performing the TLBI IPAS2LE1IS operation

To perform the TLBI IPAS2LE1IS operation:

```
TLBI IPAS2LE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0000	101

C5.6.13 TLBI VAAE1, TLB Invalidate by VA, All ASID, EL1

The TLBI VAAE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

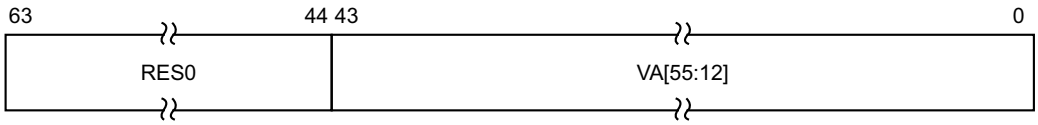
There are no configuration notes.

Attributes

TLBI VAAE1 is a 64-bit system operation.

Field descriptions

The TLBI VAAE1 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAAE1 operation

To perform the TLBI VAAE1 operation:

```
TLBI VAAE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	011

C5.6.14 TLBI VAAE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAAE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

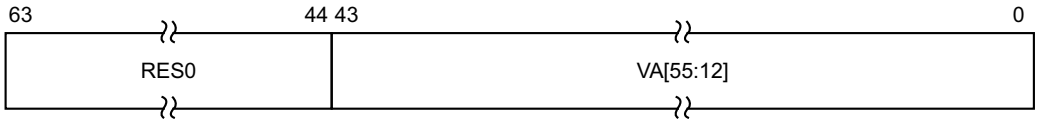
There are no configuration notes.

Attributes

TLBI VAAE1IS is a 64-bit system operation.

Field descriptions

The TLBI VAAE1IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAAE1IS operation

To perform the TLBI VAAE1IS operation:

```
TLBI VAAE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	011

C5.6.15 TLBI VAALE1, TLB Invalidate by VA, All ASID, Last level, EL1

The TLBI VAALE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

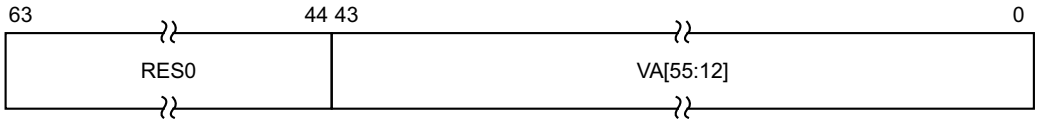
There are no configuration notes.

Attributes

TLBI VAALE1 is a 64-bit system operation.

Field descriptions

The TLBI VAALE1 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAALE1 operation

To perform the TLBI VAALE1 operation:

```
TLBI VAALE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	111

C5.6.16 TLBI VAALE1IS, TLB Invalidate by VA, All ASID, EL1, Inner Shareable

The TLBI VAALE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

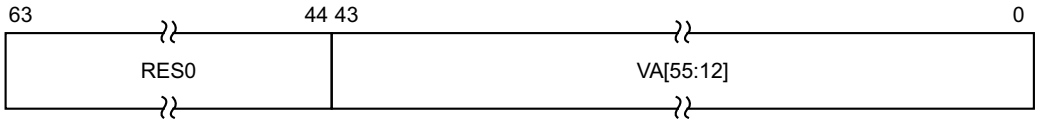
There are no configuration notes.

Attributes

TLBI VAALE1IS is a 64-bit system operation.

Field descriptions

The TLBI VAALE1IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the VA will be affected by this operation, regardless of the ASID.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAALE1IS operation

To perform the TLBI VAALE1IS operation:

```
TLBI VAALE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	111

C5.6.17 TLBI VAE1, TLB Invalidate by VA, EL1

The TLBI VAE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and ASID and the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

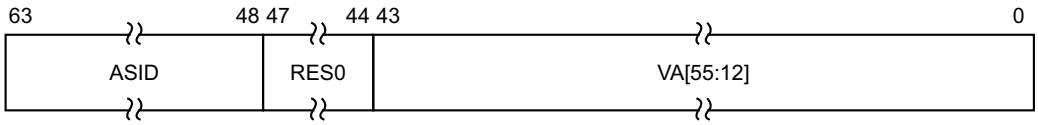
There are no configuration notes.

Attributes

TLBI VAE1 is a 64-bit system operation.

Field descriptions

The TLBI VAE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE1 operation

To perform the TLBI VAE1 operation:

```
TLBI VAE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	001

C5.6.18 TLBI VAE1IS, TLB Invalidate by VA, EL1, Inner Shareable

The TLBI VAE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

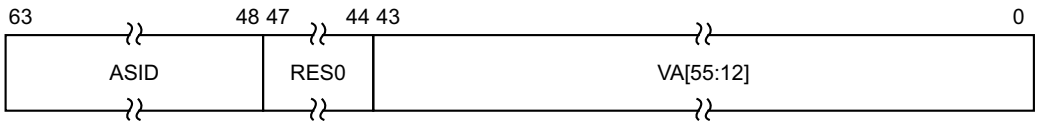
There are no configuration notes.

Attributes

TLBI VAE1IS is a 64-bit system operation.

Field descriptions

The TLBI VAE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE1IS operation

To perform the TLBI VAE1IS operation:

```
TLBI VAE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	001

C5.6.19 TLBI VAE2, TLB Invalidate by VA, EL2

The TLBI VAE2 characteristics are:

Purpose

Invalidate EL2 regime stage 1 TLB entries for the given VA.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

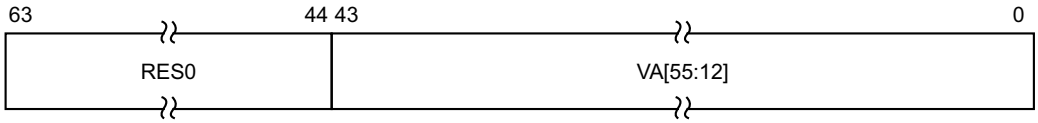
There are no configuration notes.

Attributes

TLBI VAE2 is a 64-bit system operation.

Field descriptions

The TLBI VAE2 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE2 operation

To perform the TLBI VAE2 operation:

```
TLBI VAE2, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0111	001

C5.6.20 TLBI VAE2IS, TLB Invalidate by VA, EL2, Inner Shareable

The TLBI VAE2IS characteristics are:

Purpose

Invalidate EL2 regime stage 1 TLB entries for the given VA on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

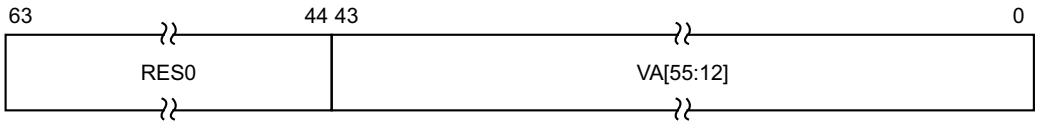
There are no configuration notes.

Attributes

TLBI VAE2IS is a 64-bit system operation.

Field descriptions

The TLBI VAE2IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE2IS operation

To perform the TLBI VAE2IS operation:

```
TLBI VAE2IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0011	001

C5.6.21 TLBI VAE3, TLB Invalidate by VA, EL3

The TLBI VAE3 characteristics are:

Purpose

Invalidate EL3 regime stage 1 TLB entries for the given VA.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

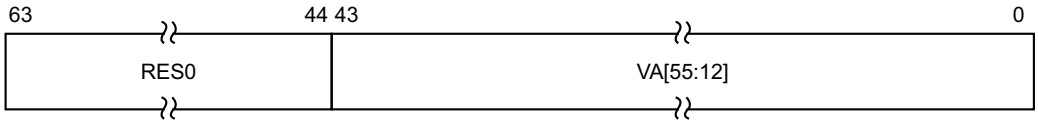
There are no configuration notes.

Attributes

TLBI VAE3 is a 64-bit system operation.

Field descriptions

The TLBI VAE3 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE3 operation

To perform the TLBI VAE3 operation:

```
TLBI VAE3, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0111	001

C5.6.22 TLBI VAE3IS, TLB Invalidate by VA, EL3, Inner Shareable

The TLBI VAE3IS characteristics are:

Purpose

Invalidate EL3 regime stage 1 TLB entries for the given VA on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

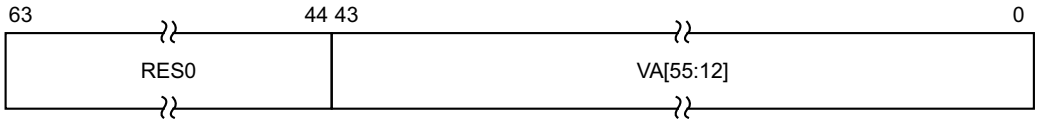
There are no configuration notes.

Attributes

TLBI VAE3IS is a 64-bit system operation.

Field descriptions

The TLBI VAE3IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VAE3IS operation

To perform the TLBI VAE3IS operation:

```
TLBI VAE3IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0011	001

C5.6.23 TLBI VALE1, TLB Invalidate by VA, Last level, EL1

The TLBI VALE1 characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

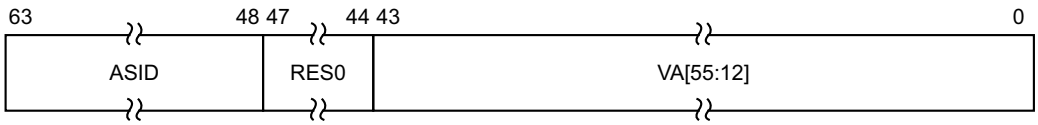
There are no configuration notes.

Attributes

TLBI VALE1 is a 64-bit system operation.

Field descriptions

The TLBI VALE1 input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE1 operation

To perform the TLBI VALE1 operation:

```
TLBI VALE1, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	101

C5.6.24 TLBI VALE1IS, TLB Invalidate by VA, Last level, EL1, Inner Shareable

The TLBI VALE1IS characteristics are:

Purpose

Invalidate EL1&0 regime stage 1 TLB entries for the last level of translation table walk, the given VA and ASID, and the current VMID, on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

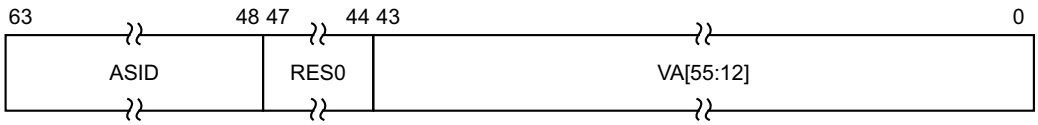
There are no configuration notes.

Attributes

TLBI VALE1IS is a 64-bit system operation.

Field descriptions

The TLBI VALE1IS input value bit assignments are:



ASID, bits [63:48]

ASID value to match. Any TLB entries that match the ASID value and VA value will be affected by this operation.

Global TLB entries that match the VA value will be affected by this operation, regardless of the value of the ASID field.

If the implementation supports 16 bits of ASID, but only 8 bits are being used in the context being invalidated, the upper bits are considered RES0 and must be written to 0 by software performing the TLB maintenance.

Bits [47:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.

- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE1IS operation

To perform the TLBI VALE1IS operation:

```
TLBI VALE1IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	101

C5.6.25 TLBI VALE2, TLB Invalidate by VA, Last level, EL2

The TLBI VALE2 characteristics are:

Purpose

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

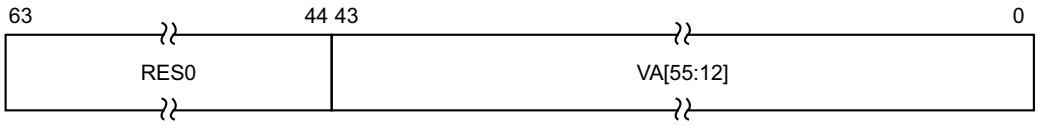
There are no configuration notes.

Attributes

TLBI VALE2 is a 64-bit system operation.

Field descriptions

The TLBI VALE2 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE2 operation

To perform the TLBI VALE2 operation:

```
TLBI VALE2, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0111	101

C5.6.26 TLBI VALE2IS, TLB Invalidate by VA, Last level, EL2, Inner Shareable

The TLBI VALE2IS characteristics are:

Purpose

Invalidate EL2 regime stage 1 TLB entries for the last level of translation table walk and the given VA on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	-

Performing this operation from EL3 is UNDEFINED if EL2 does not exist.

Configurations

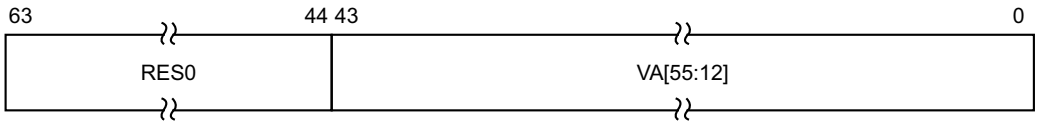
There are no configuration notes.

Attributes

TLBI VALE2IS is a 64-bit system operation.

Field descriptions

The TLBI VALE2IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE2IS operation

To perform the TLBI VALE2IS operation:

```
TLBI VALE2IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0011	101

C5.6.27 TLBI VALE3, TLB Invalidate by VA, Last level, EL3

The TLBI VALE3 characteristics are:

Purpose

Invalidate EL3 regime stage 1 TLB entries for the last level of translation table walk and the given VA.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

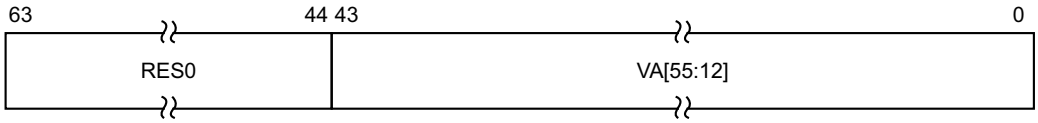
There are no configuration notes.

Attributes

TLBI VALE3 is a 64-bit system operation.

Field descriptions

The TLBI VALE3 input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE3 operation

To perform the TLBI VALE3 operation:

```
TLBI VALE3, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0111	101

C5.6.28 TLBI VALE3IS, TLB Invalidate by VA, Last level, EL3, Inner Shareable

The TLBI VALE3IS characteristics are:

Purpose

Invalidate EL3 regime stage 1 TLB entries for the last level of translation table walk and the given VA on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	-	WO	WO

Configurations

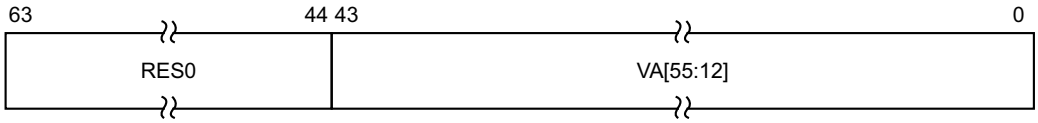
There are no configuration notes.

Attributes

TLBI VALE3IS is a 64-bit system operation.

Field descriptions

The TLBI VALE3IS input value bit assignments are:



Bits [63:44]

Reserved, RES0.

VA[55:12], bits [43:0]

Bits[55:12] of the virtual address to match. Any appropriate TLB entries that match the ASID value (if appropriate) and VA will be affected by this operation.

If the TLB maintenance instructions are targeting a translation regime that is using AArch32, and so has a VA of only 32 bits, then the software must treat bits[55:32] as RES0.

The treatment of the low-order bits of this field depends on the translation granule size, as follows:

- Where a 4KB translation granule is being used, all bits are valid and used for the invalidation.
- Where a 16KB translation granule is being used, bits [1:0] of this field are RES0 and ignored when the instruction is executed, because VA[13:12] have no effect on the operation of the instruction.
- Where a 64KB translation granule is being used, bits [3:0] of this field are RES0 and ignored when the instruction is executed, because VA[15:12] have no effect on the operation of the instruction.

Performing the TLBI VALE3IS operation

To perform the TLBI VALE3IS operation:

```
TLBI VALE3IS, <Xt>
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	110	1000	0011	101

C5.6.29 TLBI VMALLE1, TLB Invalidate by VMID, All at stage 1, EL1

The TLBI VMALLE1 characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 TLB entries for the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1 is a 64-bit system operation.

Field descriptions

The TLBI VMALLE1 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI VMALLE1 operation

To perform the TLBI VMALLE1 operation:

```
TLBI VMALLE1
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0111	000

C5.6.30 TLBI VMALLE1IS, TLB Invalidate by VMID, All at stage 1, EL1, Inner Shareable

The TLBI VMALLE1IS characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 TLB entries for the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	WO	WO	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLE1IS is a 64-bit system operation.

Field descriptions

The TLBI VMALLE1IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI VMALLE1IS operation

To perform the TLBI VMALLE1IS operation:

```
TLBI VMALLE1IS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	000	1000	0011	000

C5.6.31 TLBI VMALLS12E1, TLB Invalidate by VMID, All at Stage 1 and 2, EL1

The TLBI VMALLS12E1 characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1 is a 64-bit system operation.

Field descriptions

The TLBI VMALLS12E1 operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI VMALLS12E1 operation

To perform the TLBI VMALLS12E1 operation:

```
TLBI VMALLS12E1
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0111	110

C5.6.32 TLBI VMALLS12E1IS, TLB Invalidate by VMID, All at Stage 1 and 2, EL1, Inner Shareable

The TLBI VMALLS12E1IS characteristics are:

Purpose

Invalidate all EL1&0 regime stage 1 and 2 TLB entries for the current VMID on all PEs in the same Inner Shareable domain.

This register is part of the TLB maintenance instructions functional group.

Usage constraints

This operation can be performed at the exception levels shown below:

EL0	EL1 (NS)	EL1 (S)	EL2	EL3 (SCR.NS=1)	EL3 (SCR.NS=0)
-	-	-	WO	WO	WO

If EL3 is implemented, the translations that are invalidated are those associated with either the Secure or Non-secure address space, depending on the value of SCR_EL3.NS.

Configurations

There are no configuration notes.

Attributes

TLBI VMALLS12E1IS is a 64-bit system operation.

Field descriptions

The TLBI VMALLS12E1IS operation ignores the value in the register specified by the instruction used to perform this operation. Software does not have to write a value to the register before issuing this instruction.

Performing the TLBI VMALLS12E1IS operation

To perform the TLBI VMALLS12E1IS operation:

```
TLBI VMALLS12E1IS
```

The operation is encoded as follows:

op0	op1	CRn	CRm	op2
01	100	1000	0011	110

Chapter C6
A64 Base Instruction Descriptions

This chapter describes the A64 base instructions.

It contains the following sections:

C6.1 Introduction

This chapter provides information on key aspects of the base instructions, and an alphabetic list of instructions from the following functional groups:

- Branch, Exception generation, and system instructions.
- Loads and stores associated with the general-purpose registers.
- Data processing (immediate).
- Data processing (register).

A64 instruction index by encoding on page C4-174 provides an overview of the instruction encodings as well as of the instruction classes within their functional groups.

The base instruction descriptions include:

- *Register size* on page C6-383.
- *Use of the PC* on page C6-384.
- *Use of the stack pointer* on page C6-385.
- *Condition flags and related instructions* on page C6-386.

C6.2 Register size

Most data processing, comparison, and conversion instructions that use the general-purpose registers as the source or destination operand have two instruction variants that operate on either a 32-bit or a 64-bit value.

Where a 32-bit instruction form is selected, the following holds:

- The upper 32 bits of the source registers are ignored.
- The upper 32 bits of the destination register are set to zero.
- Right shifts and right rotates inject at bit[31], not at bit[63].
- The condition flags, where set by the instruction, are computed from the lower 32 bits.

This distinction applies even when the results of a 32-bit instruction form are indistinguishable from the lower 32 bits computed by the equivalent 64-bit instruction form. For example, a 32-bit bitwise `ORR` could be performed using a 64-bit `ORR` and simply ignoring the top 32 bits of the result. However, the A64 instruction set includes separate 32-bit and 64-bit forms of the `ORR` instruction.

As well as distinct sign-extend or zero-extend instructions, the A64 instruction set also provides the ability to extend and shift the final source register of an `ADD`, `SUB`, `ADDS`, `or SUBS` instruction and the index register of a Load/Store instruction. This enables array index calculations involving a 64-bit array pointer and a 32-bit array index to be implemented efficiently.

The assembly language notation enables the distinct identification of registers holding 32-bit values and registers holding 64-bit values. See *Register names* on page C1-112 and *Register indexed addressing* on page C1-116.

C6.3 Use of the PC

A64 instructions have limited access to the PC. The only instructions that can read the PC are those that generate a PC relative address:

- ADR and ADRP.
- The Load register (literal) instruction class.
- Direct branches that use an immediate offset.
- The unconditional branch with link instructions, BL and BLR, that use the PC to create the return link address.

Only explicit control flow instructions can modify the PC:

- Conditional and unconditional branch and return instructions.
- Exception generation and exception return instructions.

For more details on instructions that can modify the PC, see *Branches, Exception generating, and System instructions* on page C3-126.

C6.4 Use of the stack pointer

A64 instructions can use the stack pointer only in a limited number of cases:

- Load/Store instructions use the current stack pointer as the base address:
  - When stack alignment checking is enabled by system software and the base register is SP, the current stack pointer must be initially quadword aligned, That is, it must be aligned to 16 bytes. Misalignment generates a Stack Alignment fault. See *Stack pointer alignment checking* on page D1-1416 for more information.
- Add and subtract data processing instructions in their immediate and extended register forms, use the current stack pointer as a source register or the destination register or both.
- Logical data processing instructions in their immediate form use the current stack pointer as the destination register.

C6.5 Condition flags and related instructions

The A64 base instructions that use the condition flags as an input are:

- Conditional branch. The conditional branch instruction is `B.cond`.
- Add or subtract with carry. These instruction types include instructions to perform multi-precision arithmetic and calculate checksums. The add or subtract with carry instructions are `ADC`, `ADCS`, `SBC`, and `SBCS`, or an architectural alias for these instructions.
- Conditional select with increment, negate, or invert.This instruction type conditionally selects between one source register and a second, incremented, negated, inverted, or unmodified source register. The conditional select with increment, negate, or invert instructions are `CSINC`, `CSINV`, and `CSNEG`.

  These instructions also implement:

  — Conditional select or move. The condition flags select one of two source registers as the destination register. Short conditional sequences can be replaced by unconditional instructions followed by a conditional select, `CSEL`.

  — Conditional set. Conditionally selects between 0 and 1, or 0 and -1. This can be used to convert the condition flags to a Boolean value or mask in a general-purpose register, for example. These instructions include `CSET` and `CSETM`.
- Conditional compare. This instruction type sets the condition flags to the result of a comparison if the original condition is true, otherwise it sets the condition flags to an immediate value. It permits the flattening of nested conditional expressions without using conditional branches or performing Boolean arithmetic within the general-purpose registers.The conditional compare instructions are `CCMP` and `CCMN`.

The A64 base instructions that update the condition flags as an output are:

- Flag-setting data processing instructions, such as `ADCS`, `ADDS`, `ANDS`, `BICS`, `SBCS`, and `SUBS`, and the aliases `CMN`, `CMP`, and `TST`.
- Conditional compare instructions such as `CCMN`, `CCMP`.

The flags can be directly accessed for a read/write using the *NZCV, Condition Flags* on page C5-269.

The A64 base instructions also include conditional branch instructions that do not use the condition flags as an input:

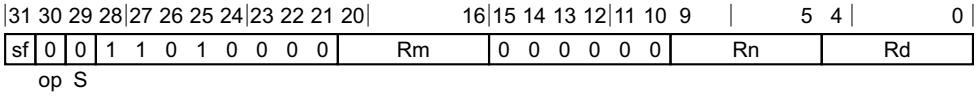
- Compare and branch if a register is zero or nonzero, `CBZ` and `CBNZ`.
- Test a single bit in a register and branch if the bit is zero or nonzero, `TBZ` and `TBNZ`.

C6.6 Alphabetical list of instructions

This section lists every instruction in the base category of the A64 instruction set. For details of the format used, see *Structure of the A64 assembler language* on page C1-111.

C6.6.1 ADC

Add with carry: `Rd = Rn + Rm + C`



32-bit variant (sf = 0)

```
ADC <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
ADC <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

if sub_op then
    operand2 = NOT(operand2);

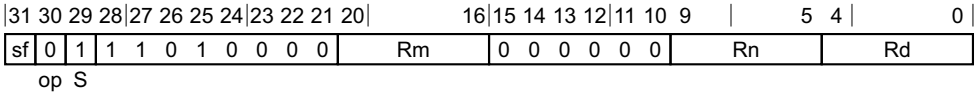
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.2 ADCS

Add with carry, setting the condition flags: `Rd = Rn + Rm + C`



32-bit variant (sf = 0)

```
ADCS <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
ADCS <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

if sub_op then
    operand2 = NOT(operand2);

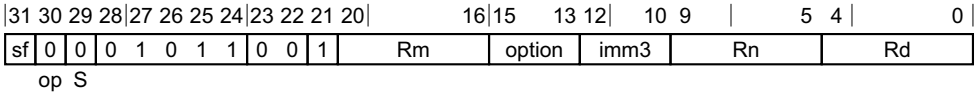
(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.3 ADD (extended register)

Add (extended register): `Rd = Rn + LSL(extend(Rm), amount)`



32-bit variant (sf = 0)

```
ADD <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant (sf = 1)

```
ADD <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

W when option = `00x`

W when option = `010`

X when option = `x11`

W when option = `10x`

W when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

`<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = `000`

UXTH when option = `001`

LSL|UXTW when option = `010`

UXTX when option = `011`

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rd or Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

<extend> For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rd or Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

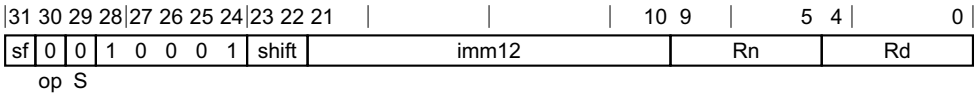
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.4 ADD (immediate)

Add (immediate): `Rd = Rn + shift(imm)`

This instruction is used by the alias MOV (to/from SP). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ADD <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant (sf = 1)

```
ADD <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
MOV (to/from SP)	`(Rd == '11111' || Rn == '11111') && IsZero(shift:imm12)`

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

LSL #12 when shift = `01`

RESERVED when shift = 1x

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = imm;
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

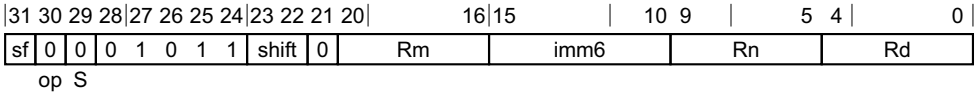
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.5 ADD (shifted register)

Add (shifted register): `Rd = Rn + shift(Rm, amount)`



32-bit variant (sf = 0)

```
ADD <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
ADD <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

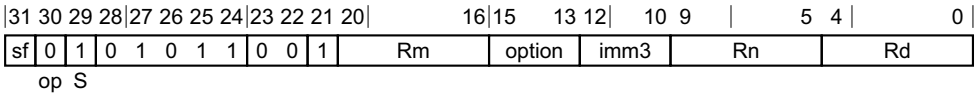
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.6 ADDS (extended register)

Add (extended register), setting the condition flags: `Rd = Rn + LSL(extend(Rm), amount)`

This instruction is used by the alias CMN (extended register). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ADDS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant (sf = 1)

```
ADDS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Alias conditions

Alias	is preferred when
CMN (extended register)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

- **W** when option = `00x`
- **W** when option = `010`
- **X** when option = `x11`
- **W** when option = `10x`
- **W** when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

<extend> For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

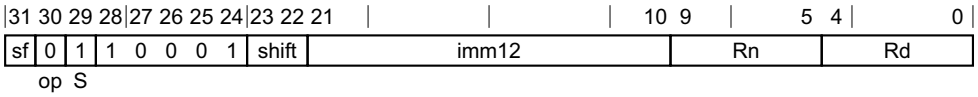
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.7 ADDS (immediate)

Add (immediate), setting the condition flags: `Rd = Rn + shift(imm)`

This instruction is used by the alias CMN (immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ADDS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant (sf = 1)

```
ADDS <Xd>, <Xn|SP>, #<imm>{, <shift>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
CMN (immediate)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

LSL #12 when shift = `01`

RESERVED when shift = `1x`

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = imm;
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

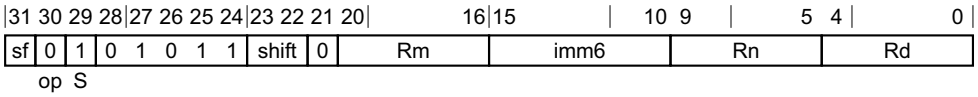
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.8 ADDS (shifted register)

Add (shifted register), setting the condition flags: `Rd = Rn + shift(Rm, amount)`

This instruction is used by the alias CMN (shifted register). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ADDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
ADDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
CMN (shifted register)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

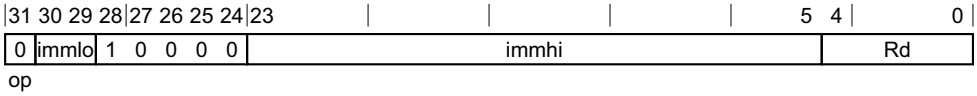
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.9 ADR

Address of label at a PC-relative offset



Literal variant

```
ADR <Xd>, <label>

integer d = UInt(Rd);
boolean page = (op == '1');
bits(64) imm;

if page then
    imm = SignExtend(immhi:immlo:Zeros(12), 64);
else
    imm = SignExtend(immhi:immlo, 64);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<label> Is the program label whose address is to be calculated. Its offset from the address of this instruction, in the range +/-1MB, is encoded in immhi:immlo.

Operation

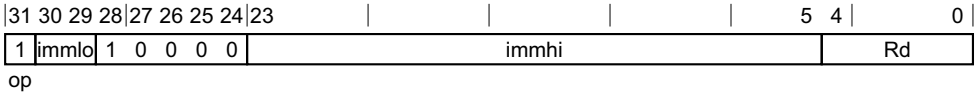
```
bits(64) base = PC[];

if page then
    base<11:0> = Zeros(12);

X[d] = base + imm;
```

C6.6.10 ADRP

Address of 4KB page at a PC-relative offset



Literal variant

```
ADRP <Xd>, <label>

integer d = UInt(Rd);
boolean page = (op == '1');
bits(64) imm;

if page then
    imm = SignExtend(immhi:immlo:Zeros(12), 64);
else
    imm = SignExtend(immhi:immlo, 64);
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<label> Is the program label whose 4KB page address is to be calculated. Its offset from the page address of this instruction, in the range +/-4GB, is encoded as immhi:immlo times 4096.

Operation

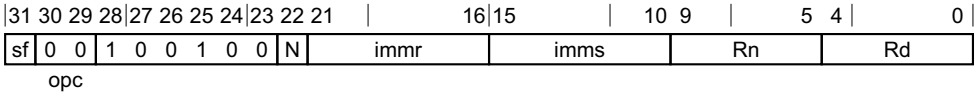
```
bits(64) base = PC[];

if page then
    base<11:0> = Zeros(12);

X[d] = base + imm;
```

C6.6.11 AND (immediate)

Bitwise AND (immediate): `Rd = Rn AND imm`



32-bit variant (sf = 0, N = 0)

```
AND <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant (sf = 1)

```
AND <Xd|SP>, <Xn>, #<imm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<imm>`	Is the bitmask immediate, encoded in N:imms:immr.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;

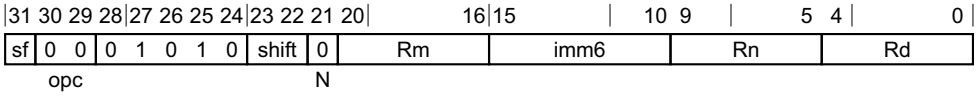
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.12 AND (shifted register)

Bitwise AND (shifted register): `Rd = Rn AND shift(Rm, amount)`



32-bit variant (sf = 0)

```
AND <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
AND <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

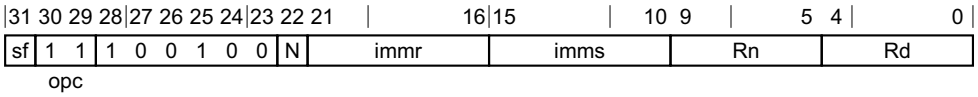
if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.13 ANDS (immediate)

Bitwise AND (immediate), setting the condition flags: `Rd = Rn AND imm`

This instruction is used by the alias TST (immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0)

```
ANDS <Wd>, <Wn>, #<imm>
```

64-bit variant (sf = 1)

```
ANDS <Xd>, <Xn>, #<imm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Alias conditions

Alias	is preferred when
TST (immediate)	`Rd == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<imm>`	Is the bitmask immediate, encoded in N:imms:immr.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;

case op of
    when LogicalOp_AND result = operand1 AND operand2;
```

```
        when LogicalOp_ORR result = operand1 OR  operand2;
        when LogicalOp_EOR result = operand1 EOR operand2;

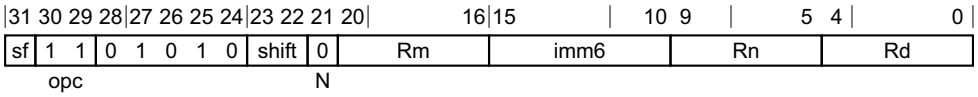
    if setflags then
        PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

    if d == 31 && !setflags then
        SP[] = result;
    else
        X[d] = result;
```

C6.6.14 ANDS (shifted register)

Bitwise AND (shifted register), setting the condition flags: `Rd = Rn AND shift(Rm, amount)`

This instruction is used by the alias TST (shifted register). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ANDS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
ANDS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Alias conditions

Alias	is preferred when
TST (shifted register)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = 10

ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

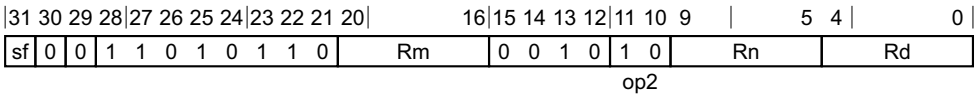
if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.15 ASR (register)

Arithmetic shift right (register): `Rd = ASR(Rn, Rm)`

This instruction is an alias of the ASRV instruction.



32-bit variant (sf = 0)

`ASR <Wd>, <Wn>, <Wm>`
is equivalent to
`ASRV <Wd>, <Wn>, <Wm>`
and is always the preferred disassembly.

64-bit variant (sf = 1)

`ASR <Xd>, <Xn>, <Xm>`
is equivalent to
`ASRV <Xd>, <Xn>, <Xm>`
and is always the preferred disassembly.

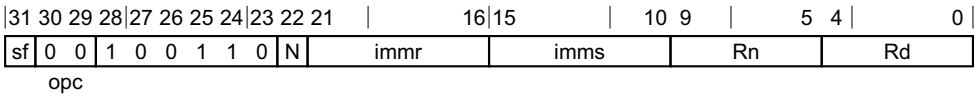
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

C6.6.16 ASR (immediate)

Arithmetic shift right (immediate): `Rd = ASR(Rn, shift)`

This instruction is an alias of the SBFM instruction.



32-bit variant (sf = 0, N = 0)

`ASR <Wd>, <Wn>, #<shift>`

is equivalent to

`SBFM <Wd>, <Wn>, #<shift>, #31`

and is the preferred disassembly when `imms == '011111'`.

64-bit variant (sf = 1, N = 1)

`ASR <Xd>, <Xn>, #<shift>`

is equivalent to

`SBFM <Xd>, <Xn>, #<shift>, #63`

and is the preferred disassembly when `imms == '111111'`.

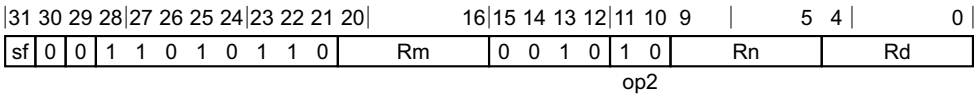
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31.
`<shift>`	For the 64-bit variant: is the shift amount, in the range 0 to 63.

C6.6.17 ASRV

Arithmetic shift right variable: `Rd = ASR(Rn, Rm)`

This instruction is used by the alias ASR (register). The alias is always the preferred disassembly.



32-bit variant (sf = 0)

```
ASRV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
ASRV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

Operation

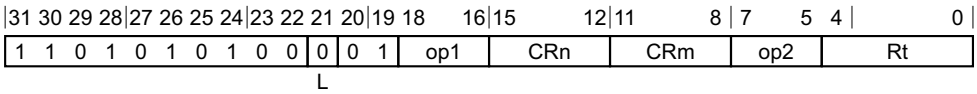
```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

C6.6.18 AT

Address translate

This instruction is an alias of the SYS instruction.



System variant

`AT <at_op>, <Xt>`

is equivalent to

`SYS #<op1>, <Cn>, <Cm>, #<op2>, <Xt>`

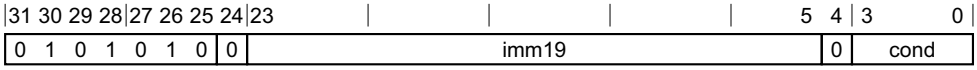
and is the preferred disassembly when `SysOp(op1,CRn,CRm,op2) == Sys_AT`.

Assembler symbols

`<at_op>`	Is an AT operation name, as listed for the AT system operation group, encoded in the op1:CRn:CRm:op2.
`<op1>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
`<Cn>`	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
`<Cm>`	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
`<op2>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.
`<Xt>`	Is the 64-bit name of the general-purpose source register, encoded in the Rt field.

C6.6.19 B.cond

Branch conditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return



19-bit signed PC-relative branch offset variant

```
B.<cond> <label>

bits(64) offset = SignExtend(imm19:'00', 64);
bits(4) condition = cond;
```

Assembler symbols

<cond> Is one of the standard conditions, encoded in the cond field in the standard way.

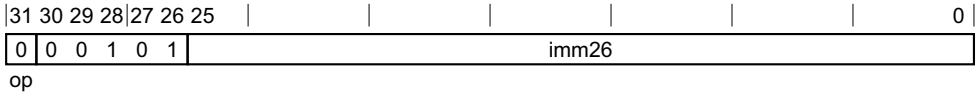
<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as imm19 times 4.

Operation

```
if ConditionHolds(condition) then
    BranchTo(PC[] + offset, BranchType_JMP);
```

C6.6.20 B

Branch unconditionally to a label at a PC-relative offset, with a hint that this is not a subroutine call or return



26-bit signed PC-relative branch offset variant

```
B <label>

BranchType branch_type = if op == '1' then BranchType_CALL else BranchType_JMP;
bits(64) offset = SignExtend(imm26:'00', 64);
```

Assembler symbols

<label>	Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as imm26 times 4.

Operation

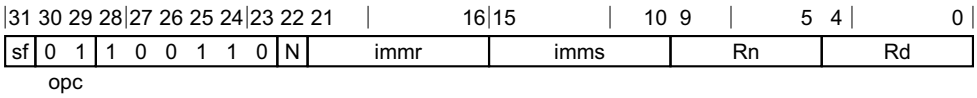
```
if branch_type == BranchType_CALL then X[30] = PC[] + 4;

BranchTo(PC[] + offset, branch_type);
```

C6.6.21 BFI

Bitfield insert, leaving other bits unchanged

This instruction is an alias of the BFM instruction.



32-bit variant (sf = 0, N = 0)

`BFI <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`BFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant (sf = 1, N = 1)

`BFI <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`BFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

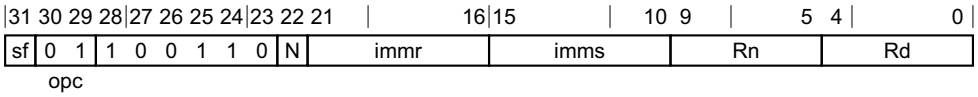
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.22 BFM

Bitfield move, leaving other bits unchanged

This instruction is used by the aliases BFI and BFXIL. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0)

```
BFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant (sf = 1, N = 1)

```
BFM <Xd>, <Xn>, #<immr>, #<imms>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

boolean inzero;
boolean extend;
integer R;
integer S;
bits(datasize) wmask;
bits(datasize) tmask;

case opc of
    when '00' inzero = TRUE;  extend = TRUE;    // SBFM
    when '01' inzero = FALSE; extend = FALSE;   // BFM
    when '10' inzero = TRUE;  extend = FALSE;   // UBFM
    when '11' UnallocatedEncoding();

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
S = UInt(imms);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Alias conditions

Alias	is preferred when
BFI	`UInt(imms) < UInt(immr)`
BFXIL	`UInt(imms) >= UInt(immr)`

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

<immr> For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the immr field.

<immr> For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the immr field.

<imms> For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the imms field.

<imms> For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the imms field.

Operation

```
bits(datasize) dst = if inzero then Zeros() else X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

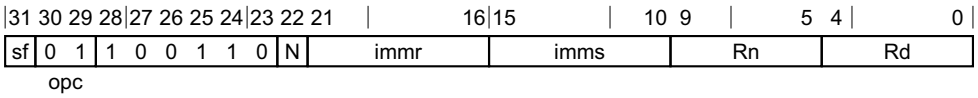
// determine extension bits (sign, zero or dest register)
bits(datasize) top = if extend then Replicate(src<S>) else dst;

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

C6.6.23 BFXIL

Bitfield extract and insert at low end, leaving other bits unchanged

This instruction is an alias of the BFM instruction.



32-bit variant (sf = 0, N = 0)

`BFXIL <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`BFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

64-bit variant (sf = 1, N = 1)

`BFXIL <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`BFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)`

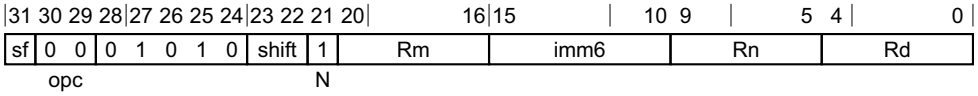
and is the preferred disassembly when `UInt(imms) >= UInt(immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.24 BIC (shifted register)

Bitwise bit clear (shifted register): `Rd = Rn AND NOT shift(Rm, amount)`



32-bit variant (sf = 0)

```
BIC <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
BIC <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

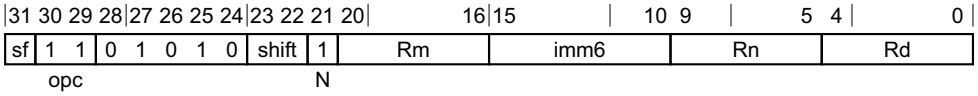
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.25 BICS (shifted register)

Bitwise bit clear (shifted register), setting the condition flags: `Rd = Rn AND NOT shift(Rm, amount)`



32-bit variant (sf = 0)

```
BICS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
BICS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

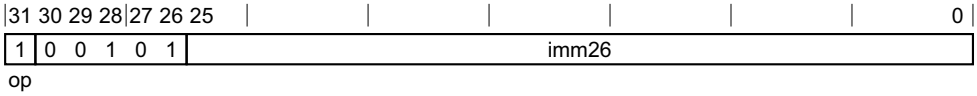
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.26 BL

Branch with link, calls a subroutine at a PC-relative offset, setting register X30 to PC + 4



26-bit signed PC-relative branch offset variant

```
BL <label>

BranchType branch_type = if op == '1' then BranchType_CALL else BranchType_JMP;
bits(64) offset = SignExtend(imm26:'00', 64);
```

Assembler symbols

<label> Is the program label to be unconditionally branched to. Its offset from the address of this instruction, in the range +/-128MB, is encoded as imm26 times 4.

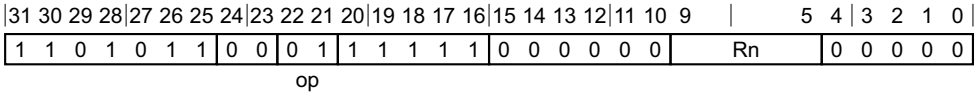
Operation

```
if branch_type == BranchType_CALL then X[30] = PC[] + 4;

BranchTo(PC[] + offset, branch_type);
```

C6.6.27 BLR

Branch with link to register, calls a subroutine at an address in a register, setting register X30 to PC + 4



Integer variant

```
BLR <Xn>

integer n = UInt(Rn);
BranchType branch_type;

case op of
    when '00' branch_type = BranchType_JMP;
    when '01' branch_type = BranchType_CALL;
    when '10' branch_type = BranchType_RET;
    otherwise UnallocatedEncoding();
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the Rn field.

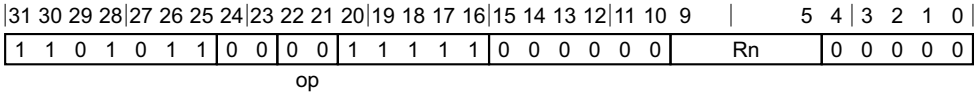
Operation

```
bits(64) target = X[n];

if branch_type == BranchType_CALL then X[30] = PC[] + 4;
BranchTo(target, branch_type);
```

C6.6.28 BR

Branch to register, branches unconditionally to an address in a register, with a hint that this is not a subroutine return



Integer variant

```
BR <Xn>

integer n = UInt(Rn);
BranchType branch_type;

case op of
    when '00' branch_type = BranchType_JMP;
    when '01' branch_type = BranchType_CALL;
    when '10' branch_type = BranchType_RET;
    otherwise UnallocatedEncoding();
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the Rn field.

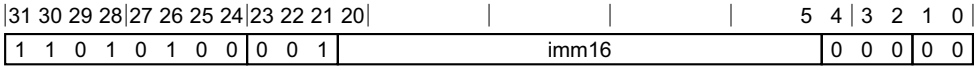
Operation

```
bits(64) target = X[n];

if branch_type == BranchType_CALL then X[30] = PC[] + 4;
BranchTo(target, branch_type);
```

C6.6.29 BRK

Self-hosted debug breakpoint



System variant

```
BRK #<imm>

bits(16) comment = imm16;
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.

Operation

```
AArch64.SoftwareBreakpoint(comment);
```

C6.6.30 CBNZ

Compare and branch if nonzero to a label at a PC-relative offset, without affecting the condition flags, and with a hint that this is not a subroutine call or return

32-bit variant (sf = 0)

```
CBNZ <Wt>, <label>
```

64-bit variant (sf = 1)

```
CBNZ <Xt>, <label>
```

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
boolean iszero = (op == '0');
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the Rt field.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the Rt field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as imm19 times 4.

Operation

```
bits(datasize) operand1 = X[t];

if IsZero(operand1) == iszero then
    BranchTo(PC[] + offset, BranchType_JMP);
```

C6.6.31 CBZ

Compare and branch if zero to a label at a PC-relative offset, without affecting the condition flags, and with a hint that this is not a subroutine call or return

32-bit variant (sf = 0)

```
CBZ <Wt>, <label>
```

64-bit variant (sf = 1)

```
CBZ <Xt>, <label>
```

```
integer t = UInt(Rt);
integer datasize = if sf == '1' then 64 else 32;
boolean iszero = (op == '0');
bits(64) offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be tested, encoded in the Rt field.
<Xt>	Is the 64-bit name of the general-purpose register to be tested, encoded in the Rt field.
<label>	Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-1MB, is encoded as imm19 times 4.

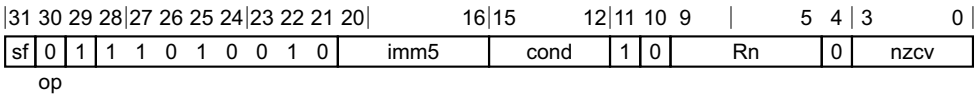
Operation

```
bits(datasize) operand1 = X[t];

if IsZero(operand1) == iszero then
    BranchTo(PC[] + offset, BranchType_JMP);
```

C6.6.32 CCMN (immediate)

Conditional compare negative (immediate), setting condition flags to result of comparison or an immediate value:
`flags = if cond then compare(Rn, #-imm) else #nzcv`



32-bit variant (sf = 0)

```
CCMN <Wn>, #<imm>, #<nzcv>, <cond>
```

64-bit variant (sf = 1)

```
CCMN <Xn>, #<imm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
<imm>	Is a five bit unsigned (positive) immediate encoded in the imm5 field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
<cond>	Is one of the standard conditions, encoded in the cond field in the standard way.

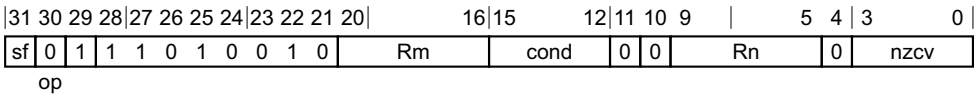
Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;
bit carry_in = '0';

if ConditionHolds(condition) then
    if sub_op then
        operand2 = NOT(operand2);
        carry_in = '1';
    (-, flags) = AddWithCarry(operand1, operand2, carry_in);
PSTATE.<N,Z,C,V> = flags;
```

C6.6.33 CCMN (register)

Conditional compare negative (register), setting condition flags to result of comparison or an immediate value:
`flags = if cond then compare(Rn, -Rm) else #nzcv`



32-bit variant (sf = 0)

```
CCMN <Wn>, <Wm>, #<nzcv>, <cond>
```

64-bit variant (sf = 1)

```
CCMN <Xn>, <Xm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
<Wm>	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
<Xm>	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
<cond>	Is one of the standard conditions, encoded in the cond field in the standard way.

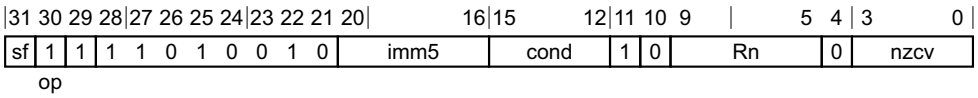
Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bit carry_in = '0';

if ConditionHolds(condition) then
    if sub_op then
        operand2 = NOT(operand2);
        carry_in = '1';
    (-, flags) = AddWithCarry(operand1, operand2, carry_in);
PSTATE.<N,Z,C,V> = flags;
```

C6.6.34 CCMP (immediate)

Conditional compare (immediate), setting condition flags to result of comparison or an immediate value: `flags = if cond then compare(Rn, #imm) else #nzcv`



32-bit variant (sf = 0)

```
CCMP <Wn>, #<imm>, #<nzcv>, <cond>
```

64-bit variant (sf = 1)

```
CCMP <Xn>, #<imm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
bits(datasize) imm = ZeroExtend(imm5, datasize);
```

Assembler symbols

<Wn>	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
<Xn>	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
<imm>	Is a five bit unsigned (positive) immediate encoded in the imm5 field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
<cond>	Is one of the standard conditions, encoded in the cond field in the standard way.

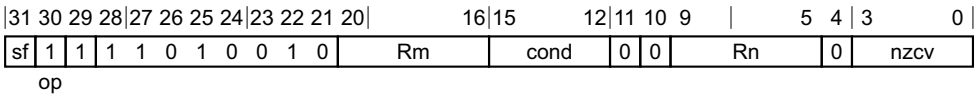
Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;
bit carry_in = '0';

if ConditionHolds(condition) then
    if sub_op then
        operand2 = NOT(operand2);
        carry_in = '1';
    (-, flags) = AddWithCarry(operand1, operand2, carry_in);
PSTATE.<N,Z,C,V> = flags;
```

C6.6.35 CCMP (register)

Conditional compare (register), setting condition flags to result of comparison or an immediate value: `flags = if cond then compare(Rn, Rm) else #nzcv`



32-bit variant (sf = 0)

```
CCMP <Wn>, <Wm>, #<nzcv>, <cond>
```

64-bit variant (sf = 1)

```
CCMP <Xn>, <Xm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
```

Assembler symbols

`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<nzcv>`	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

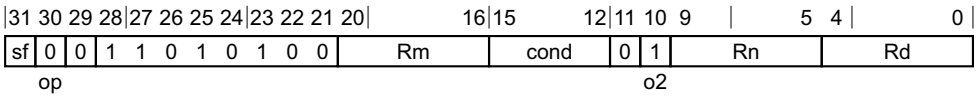
```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bit carry_in = '0';

if ConditionHolds(condition) then
    if sub_op then
        operand2 = NOT(operand2);
        carry_in = '1';
    (-, flags) = AddWithCarry(operand1, operand2, carry_in);
PSTATE.<N,Z,C,V> = flags;
```

C6.6.36 CINC

Conditional increment: `Rd = if cond then Rn+1 else Rn`

This instruction is an alias of the CSINC instruction.



32-bit variant (sf = 0)

`CINC <Wd>, <Wn>, <cond>`

is equivalent to

`CSINC <Wd>, <Wn>, <Wn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn != '11111' && cond != '111x'`.

64-bit variant (sf = 1)

`CINC <Xd>, <Xn>, <cond>`

is equivalent to

`CSINC <Xd>, <Xn>, <Xn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn != '11111' && cond != '111x'`.

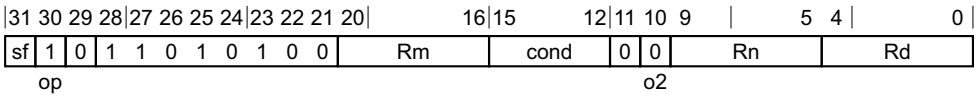
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the cond field with its least significant bit inverted.

C6.6.37 CINV

Conditional invert: `Rd = if cond then NOT(Rn) else Rn`

This instruction is an alias of the CSINV instruction.



32-bit variant (sf = 0)

`CINV <Wd>, <Wn>, <cond>`

is equivalent to

`CSINV <Wd>, <Wn>, <Wn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn != '11111' && cond != '111x'`.

64-bit variant (sf = 1)

`CINV <Xd>, <Xn>, <cond>`

is equivalent to

`CSINV <Xd>, <Xn>, <Xn>, invert(<cond>)`

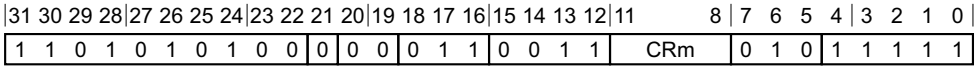
and is the preferred disassembly when `Rn == Rm && Rn != '11111' && cond != '111x'`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the cond field with its least significant bit inverted.

C6.6.38 CLREX

Clear exclusive monitor



System variant

```
CLREX {#<imm>}

// CRm field is ignored
```

Assembler symbols

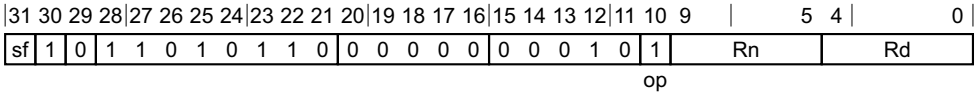
<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the CRm field.

Operation

```
ClearExclusiveLocal(ProcessorID());
```

C6.6.39 CLS

Count leading sign bits: `Rd = CLS(Rn)`



32-bit variant (sf = 0)

```
CLS <Wd>, <Wn>
```

64-bit variant (sf = 1)

```
CLS <Xd>, <Xn>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
CountOp opcode = if op == '0' then CountOp_CLZ else CountOp_CLS;
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

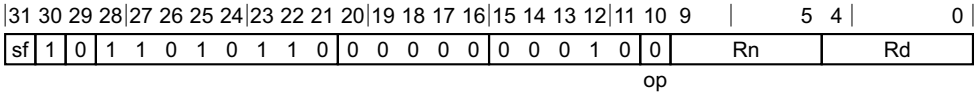
```
integer result;
bits(datasize) operand1 = X[n];

if opcode == CountOp_CLZ then
    result = CountLeadingZeroBits(operand1);
else
    result = CountLeadingSignBits(operand1);

X[d] = result<datasize-1:0>;
```

C6.6.40 CLZ

Count leading zero bits: `Rd = CLZ(Rn)`



32-bit variant (sf = 0)

```
CLZ <Wd>, <Wn>
```

64-bit variant (sf = 1)

```
CLZ <Xd>, <Xn>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
CountOp opcode = if op == '0' then CountOp_CLZ else CountOp_CLS;
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

```
integer result;
bits(datasize) operand1 = X[n];

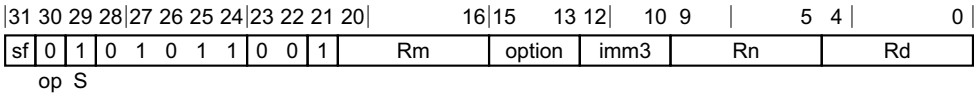
if opcode == CountOp_CLZ then
    result = CountLeadingZeroBits(operand1);
else
    result = CountLeadingSignBits(operand1);

X[d] = result<datasize-1:0>;
```

C6.6.41 CMN (extended register)

Compare negative (extended register), setting the condition flags and discarding the result: `Rn + LSL(extend(Rm), amount)`

This instruction is an alias of the ADDS (extended register) instruction.



32-bit variant (sf = 0)

`CMN <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

is equivalent to

`ADDS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

`CMN <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

is equivalent to

`ADDS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

- **W** when option = `00x`
- **W** when option = `010`
- **X** when option = `x11`
- **W** when option = `10x`
- **W** when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

`<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

- **UXTB** when option = `000`
- **UXTH** when option = `001`
- **LSL|UXTW** when option = `010`
- **UXTX** when option = `011`
- **SXTB** when option = `100`
- **SXTH** when option = `101`
- **SXTW** when option = `110`

SXTX when option = 111

If Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

<extend> For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

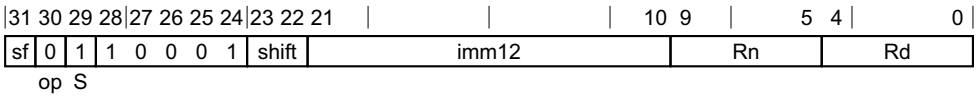
If Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

C6.6.42 CMN (immediate)

Compare negative (immediate), setting the condition flags and discarding the result: `Rn + shift(imm)`

This instruction is an alias of the ADDS (immediate) instruction.



32-bit variant (sf = 0)

`CMN <Wn|WSP>, #<imm>{, <shift>}`

is equivalent to

`ADDS WZR, <Wn|WSP>, #<imm> {, <shift>}`

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

`CMN <Xn|SP>, #<imm>{, <shift>}`

is equivalent to

`ADDS XZR, <Xn|SP>, #<imm> {, <shift>}`

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

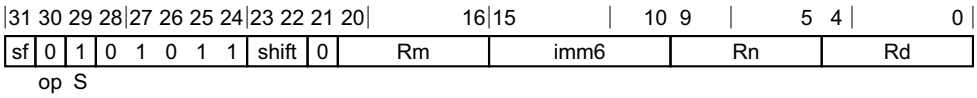
LSL #12 when shift = `01`

RESERVED when shift = 1x

C6.6.43 CMN (shifted register)

Compare negative (shifted register), setting the condition flags and discarding the result: `Rn + shift(Rm, amount)`

This instruction is an alias of the ADDS (shifted register) instruction.



32-bit variant (sf = 0)

```
CMN <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS WZR, <Wn>, <Wm> {, <shift> #<amount>}
```

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

```
CMN <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ADDS XZR, <Xn>, <Xm> {, <shift> #<amount>}
```

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = `11`

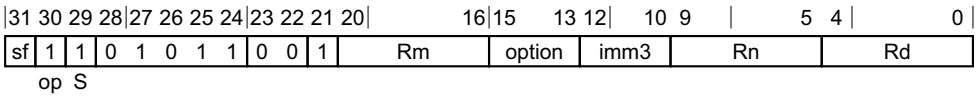
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

C6.6.44 CMP (extended register)

Compare (extended register), setting the condition flags and discarding the result: `Rn - LSL(extend(Rm), amount)`

This instruction is an alias of the SUBS (extended register) instruction.



32-bit variant (sf = 0)

`CMP <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

is equivalent to

`SUBS WZR, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}`

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

`CMP <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

is equivalent to

`SUBS XZR, <Xn|SP>, <R><m>{, <extend> {#<amount>}}`

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

- **W** when option = `00x`
- **W** when option = `010`
- **X** when option = `x11`
- **W** when option = `10x`
- **W** when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

`<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

- **UXTB** when option = `000`
- **UXTH** when option = `001`
- **LSL|UXTW** when option = `010`
- **UXTX** when option = `011`
- **SXTB** when option = `100`
- **SXTH** when option = `101`
- **SXTW** when option = `110`
- **SXTX** when option = `111`

If Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

`<extend>` For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = `000`

UXTH when option = `001`

UXTW when option = `010`

LSL|UXTX when option = `011`

SXTB when option = `100`

SXTH when option = `101`

SXTW when option = `110`

SXTX when option = `111`

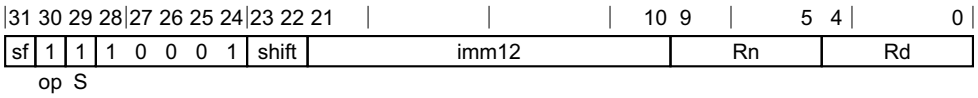
If Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

`<amount>` Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

C6.6.45 CMP (immediate)

Compare (immediate), setting the condition flags and discarding the result: `Rn - shift(imm)`

This instruction is an alias of the SUBS (immediate) instruction.



32-bit variant (sf = 0)

```
CMP <Wn|WSP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS WZR, <Wn|WSP>, #<imm> {, <shift>}
```

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

```
CMP <Xn|SP>, #<imm>{, <shift>}
```

is equivalent to

```
SUBS XZR, <Xn|SP>, #<imm> {, <shift>}
```

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

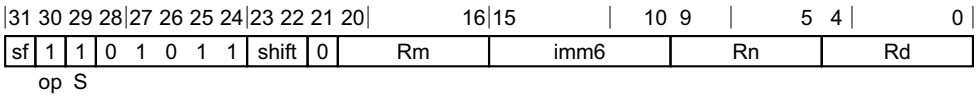
LSL #12 when shift = `01`

RESERVED when shift = 1x

C6.6.46 CMP (shifted register)

Compare (shifted register), setting the condition flags and discarding the result: `Rn - shift(Rm,amount)`

This instruction is an alias of the SUBS (shifted register) instruction.



32-bit variant (sf = 0)

```
CMP <Wn>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS WZR, <Wn>, <Wm> {, <shift> #<amount>}
```

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

```
CMP <Xn>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
SUBS XZR, <Xn>, <Xm> {, <shift> #<amount>}
```

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = `11`

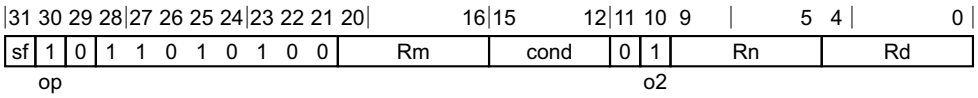
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

C6.6.47 CNEG

Conditional negate: `Rd = if cond then -Rn else Rn`

This instruction is an alias of the CSNEG instruction.



32-bit variant (sf = 0)

`CNEG <Wd>, <Wn>, <cond>`

is equivalent to

`CSNEG <Wd>, <Wn>, <Wn>, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && cond != '111x'`.

64-bit variant (sf = 1)

`CNEG <Xd>, <Xn>, <cond>`

is equivalent to

`CSNEG <Xd>, <Xn>, <Xn>, invert(<cond>)`

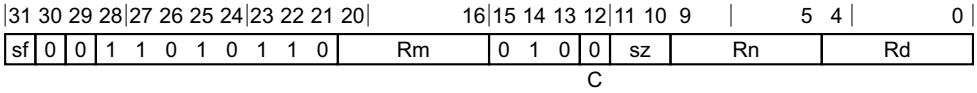
and is the preferred disassembly when `Rn == Rm && cond != '111x'`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the cond field with its least significant bit inverted.

C6.6.48 CRC32B, CRC32H, CRC32W, CRC32X

CRC-32 checksum from byte, halfword, word or doubleword: `Wd = CRC32(Wn, Rm<n:0>) // n = 7, 15, 31, 63`



CRC32B variant (sf = 0, sz = 00)

```
CRC32B <Wd>, <Wn>, <Wm>
```

CRC32H variant (sf = 0, sz = 01)

```
CRC32H <Wd>, <Wn>, <Wm>
```

CRC32W variant (sf = 0, sz = 10)

```
CRC32W <Wd>, <Wn>, <Wm>
```

CRC32X variant (sf = 1, sz = 11)

```
CRC32X <Wd>, <Wn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if ! HaveCRCExt() then UnallocatedEncoding();
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);   // 2-bit size field -> 8, 16, 32, 64
boolean crc32c = (C == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose accumulator output register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the general-purpose accumulator input register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the general-purpose data source register, encoded in the Rm field.

`<Wm>` Is the 32-bit name of the general-purpose data source register, encoded in the Rm field.

Operation

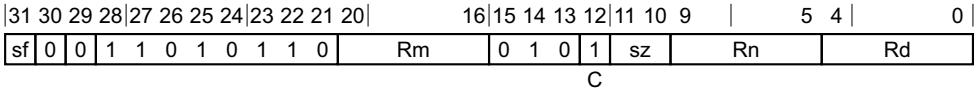
```
bits(32)      acc     = X[n];   // accumulator
bits(size)    val     = X[m];   // input value
bits(32)      poly    = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;

bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

C6.6.49 CRC32CB, CRC32CH, CRC32CW, CRC32CX

CRC-32C checksum from byte, halfword, word, or doubleword: `Wd = CRC32C(Wn, Rm<n:0>) // n = 7, 15, 31, 63`



CRC32CB variant (sf = 0, sz = 00)

```
CRC32CB <Wd>, <Wn>, <Wm>
```

CRC32CH variant (sf = 0, sz = 01)

```
CRC32CH <Wd>, <Wn>, <Wm>
```

CRC32CW variant (sf = 0, sz = 10)

```
CRC32CW <Wd>, <Wn>, <Wm>
```

CRC32CX variant (sf = 1, sz = 11)

```
CRC32CX <Wd>, <Wn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if ! HaveCRCExt() then UnallocatedEncoding();
if sf == '1' && sz != '11' then UnallocatedEncoding();
if sf == '0' && sz == '11' then UnallocatedEncoding();
integer size = 8 << UInt(sz);   // 2-bit size field -> 8, 16, 32, 64
boolean crc32c = (C == '1');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose accumulator output register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose accumulator input register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the general-purpose data source register, encoded in the Rm field.
`<Wm>`	Is the 32-bit name of the general-purpose data source register, encoded in the Rm field.

Operation

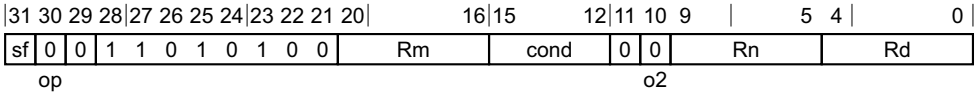
```
bits(32)      acc     = X[n];   // accumulator
bits(size)    val     = X[m];   // input value
bits(32)      poly    = (if crc32c then 0x1EDC6F41 else 0x04C11DB7)<31:0>;

bits(32+size) tempacc = BitReverse(acc):Zeros(size);
bits(size+32) tempval = BitReverse(val):Zeros(32);

// Poly32Mod2 on a bitstring does a polynomial Modulus over {0,1} operation
X[d] = BitReverse(Poly32Mod2(tempacc EOR tempval, poly));
```

C6.6.50 CSEL

Conditional select, returning the first or second input: `Rd = if cond then Rn else Rm`



32-bit variant (sf = 0)

```
CSEL <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant (sf = 1)

```
CSEL <Xd>, <Xn>, <Xm>, <cond>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) condition = cond;
boolean else_inv = (op == '1');
boolean else_inc = (o2 == '1');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

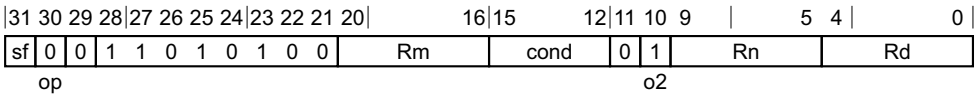
if ConditionHolds(condition) then
    result = operand1;
else
    result = operand2;
    if else_inv then result = NOT(result);
    if else_inc then result = result + 1;

X[d] = result;
```

C6.6.51 CSET

Conditional set: `Rd = if cond then 1 else 0`

This instruction is an alias of the CSINC instruction.



32-bit variant (sf = 0)

`CSET <Wd>, <cond>`

is equivalent to

`CSINC <Wd>, WZR, WZR, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn == '11111' && cond != '111x'`.

64-bit variant (sf = 1)

`CSET <Xd>, <cond>`

is equivalent to

`CSINC <Xd>, XZR, XZR, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn == '11111' && cond != '111x'`.

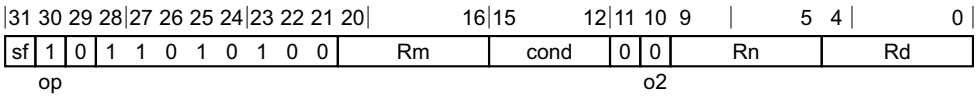
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the cond field with its least significant bit inverted.

C6.6.52 CSETM

Conditional set mask: `Rd = if cond then -1 else 0`

This instruction is an alias of the CSINV instruction.



32-bit variant (sf = 0)

`CSETM <Wd>, <cond>`

is equivalent to

`CSINV <Wd>, WZR, WZR, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn == '11111' && cond != '111x'`.

64-bit variant (sf = 1)

`CSETM <Xd>, <cond>`

is equivalent to

`CSINV <Xd>, XZR, XZR, invert(<cond>)`

and is the preferred disassembly when `Rn == Rm && Rn == '11111' && cond != '111x'`.

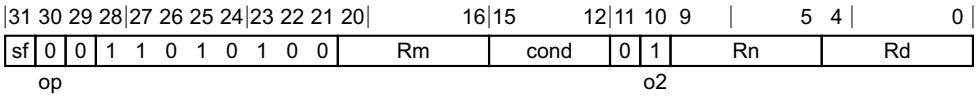
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<cond>`	Is one of the standard conditions, excluding AL and NV, encoded in the cond field with its least significant bit inverted.

C6.6.53 CSINC

Conditional select increment, returning the first input or incremented second input: `Rd = if cond then Rn else (Rm + 1)`

This instruction is used by the aliases CINC and CSET. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
CSINC <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant (sf = 1)

```
CSINC <Xd>, <Xn>, <Xm>, <cond>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) condition = cond;
boolean else_inv = (op == '1');
boolean else_inc = (o2 == '1');
```

Alias conditions

Alias	is preferred when
CINC	`Rn == Rm && Rn != '11111' && cond != '111x'`
CSET	`Rn == Rm && Rn == '11111' && cond != '111x'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(condition) then
    result = operand1;
```

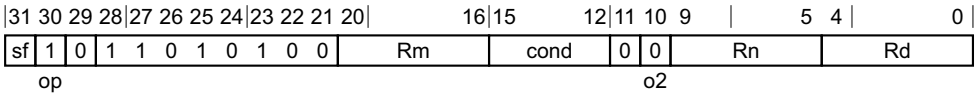
```
else
    result = operand2;
    if else_inv then result = NOT(result);
    if else_inc then result = result + 1;

X[d] = result;
```

C6.6.54 CSINV

Conditional select inversion, returning the first input or inverted second input: `Rd = if cond then Rn else NOT (Rm)`

This instruction is used by the aliases CINV and CSETM. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
CSINV <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant (sf = 1)

```
CSINV <Xd>, <Xn>, <Xm>, <cond>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) condition = cond;
boolean else_inv = (op == '1');
boolean else_inc = (o2 == '1');
```

Alias conditions

Alias	is preferred when
CINV	`Rn == Rm && Rn != '11111' && cond != '111x'`
CSETM	`Rn == Rm && Rn == '11111' && cond != '111x'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(condition) then
    result = operand1;
else
```

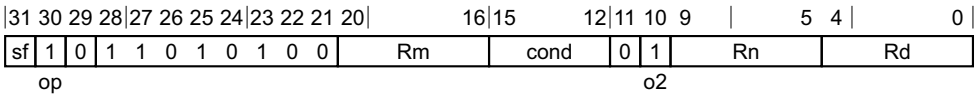
```
    result = operand2;
    if else_inv then result = NOT(result);
    if else_inc then result = result + 1;

X[d] = result;
```

C6.6.55 CSNEG

Conditional select negation, returning the first input or negated second input: `Rd = if cond then Rn else -Rm`

This instruction is used by the alias CNEG. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
CSNEG <Wd>, <Wn>, <Wm>, <cond>
```

64-bit variant (sf = 1)

```
CSNEG <Xd>, <Xn>, <Xm>, <cond>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
bits(4) condition = cond;
boolean else_inv = (op == '1');
boolean else_inc = (o2 == '1');
```

Alias conditions

Alias	is preferred when
CNEG	`Rn == Rm && cond != '111x'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

if ConditionHolds(condition) then
    result = operand1;
else
    result = operand2;
    if else_inv then result = NOT(result);
```

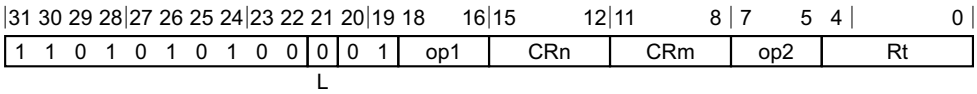
```
    if else_inc then result = result + 1;

X[d] = result;
```

C6.6.56 DC

Data cache operation

This instruction is an alias of the SYS instruction.



System variant

`DC <dc_op>, <Xt>`

is equivalent to

`SYS #<op1>, <Cn>, <Cm>, #<op2>, <Xt>`

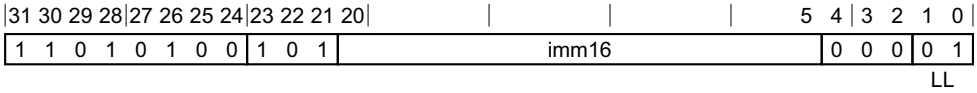
and is the preferred disassembly when `SysOp(op1,CRn,CRm,op2) == Sys_DC`.

Assembler symbols

`<dc_op>`	Is a DC operation name, as listed for the DC system operation group, encoded in op1:CRn:CRm:op2.
`<op1>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
`<Cn>`	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
`<Cm>`	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
`<op2>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.
`<Xt>`	Is the 64-bit name of the general-purpose source register, encoded in the Rt field.

C6.6.57 DCPS1

Debug switch to exception level 1



System variant

```
DCPS1 {#<imm>}

bits(2) target_level = LL;
if !Halted() || LL == '00' then UnallocatedEncoding();
```

Assembler symbols

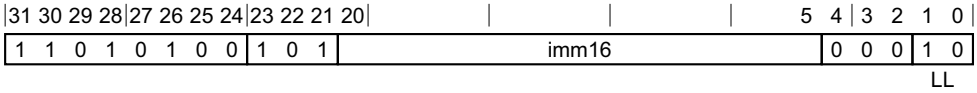
<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the imm16 field.

Operation

```
DCPSInstruction(target_level);
```

C6.6.58 DCPS2

Debug switch to exception level 2



System variant

```
DCPS2 {#<imm>}

bits(2) target_level = LL;
if !Halted() || LL == '00' then UnallocatedEncoding();
```

Assembler symbols

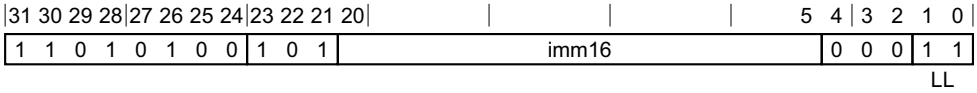
<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the imm16 field.

Operation

```
DCPSInstruction(target_level);
```

C6.6.59 DCPS3

Debug switch to exception level 3



System variant

```
DCPS3 {#<imm>}

bits(2) target_level = LL;
if !Halted() || LL == '00' then UnallocatedEncoding();
```

Assembler symbols

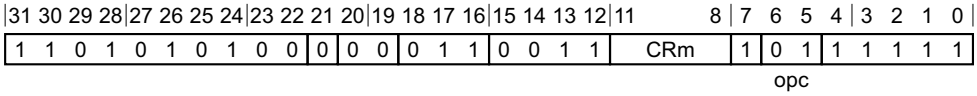
<imm> Is an optional 16-bit unsigned immediate, in the range 0 to 65535, defaulting to 0 and encoded in the imm16 field.

Operation

```
DCPSInstruction(target_level);
```

C6.6.60 DMB

Data memory barrier



System variant

```
DMB <option>|#<imm>

MemBarrierOp op;
MBReqDomain domain;
MBReqTypes types;

case opc of
    when '00' op = MemBarrierOp_DSB;
    when '01' op = MemBarrierOp_DMB;
    when '10' op = MemBarrierOp_ISB;
    otherwise UnallocatedEncoding();

case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
    otherwise
        types = MBReqTypes_All;
        domain = MBReqDomain_FullSystem;
```

Assembler symbols

`<option>` Is a barrier option name, encoded in the CRm field:

OSHLD	when CRm = `0001`
OSHST	when CRm = `0010`
OSH	when CRm = `0011`
NSHLD	when CRm = `0101`
NSHST	when CRm = `0110`
NSH	when CRm = `0111`
#<imm>	when CRm = `xx00`
ISHLD	when CRm = `1001`
ISHST	when CRm = `1010`
ISH	when CRm = `1011`
LD	when CRm = `1101`
ST	when CRm = `1110`
SY	when CRm = `1111`

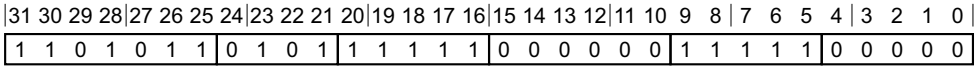
`<imm>` Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the CRm field.

Operation

```
case op of
    when MemBarrierOp_DSB
        DataSynchronizationBarrier(domain, types);
    when MemBarrierOp_DMB
        DataMemoryBarrier(domain, types);
    when MemBarrierOp_ISB
        InstructionSynchronizationBarrier();
```

C6.6.61 DRPS

Debug restore processor state



System variant

DRPS

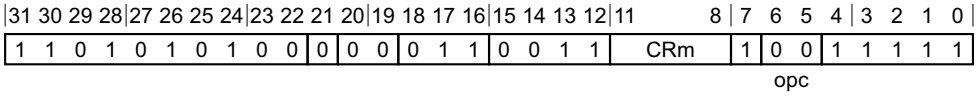
```
if !Halted() || PSTATE.EL == EL0 then UnallocatedEncoding();
```

Operation

```
DRPSInstruction();
```

C6.6.62 DSB

Data synchronization barrier



System variant

```
DSB <option>|#<imm>

MemBarrierOp op;
MBReqDomain domain;
MBReqTypes types;

case opc of
    when '00' op = MemBarrierOp_DSB;
    when '01' op = MemBarrierOp_DMB;
    when '10' op = MemBarrierOp_ISB;
    otherwise UnallocatedEncoding();

case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
    otherwise
        types = MBReqTypes_All;
        domain = MBReqDomain_FullSystem;
```

Assembler symbols

`<option>` Is a barrier option name, encoded in the CRm field:

OSHLD	when CRm = `0001`
OSHST	when CRm = `0010`
OSH	when CRm = `0011`
NSHLD	when CRm = `0101`
NSHST	when CRm = `0110`
NSH	when CRm = `0111`
#<imm>	when CRm = `xx00`
ISHLD	when CRm = `1001`
ISHST	when CRm = `1010`
ISH	when CRm = `1011`
LD	when CRm = `1101`
ST	when CRm = `1110`
SY	when CRm = `1111`

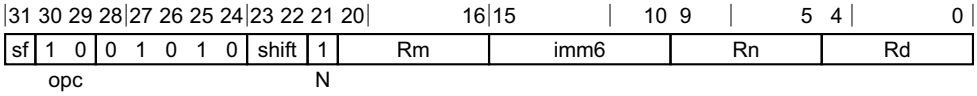
`<imm>` Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the CRm field.

Operation

```
case op of
    when MemBarrierOp_DSB
        DataSynchronizationBarrier(domain, types);
    when MemBarrierOp_DMB
        DataMemoryBarrier(domain, types);
    when MemBarrierOp_ISB
        InstructionSynchronizationBarrier();
```

C6.6.63 EON (shifted register)

Bitwise exclusive OR NOT (shifted register): `Rd = Rn EOR NOT shift(Rm, amount)`



32-bit variant (sf = 0)

```
EON <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
EON <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

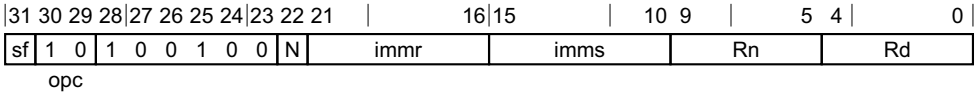
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.64 EOR (immediate)

Bitwise exclusive OR (immediate): `Rd = Rn EOR imm`



32-bit variant (sf = 0, N = 0)

```
EOR <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant (sf = 1)

```
EOR <Xd|SP>, <Xn>, #<imm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<imm>`	Is the bitmask immediate, encoded in N:imms:immr.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;

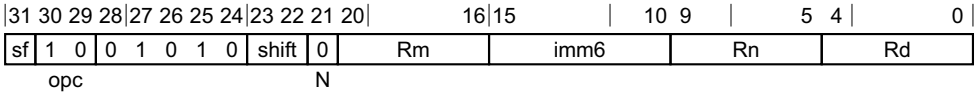
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.65 EOR (shifted register)

Bitwise exclusive OR (shifted register): `Rd = Rn EOR shift(Rm, amount)`



32-bit variant (sf = 0)

```
EOR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
EOR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of

    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

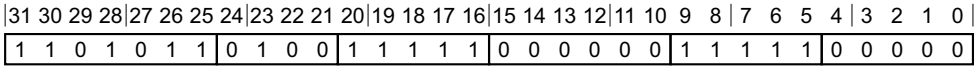
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.66 ERET

Exception return using current ELR and SPSR



System variant

```
ERET

if PSTATE.EL == EL0 then UnallocatedEncoding();
```

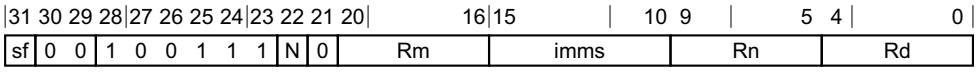
Operation

```
AArch64.ExceptionReturn(ELR[], SPSR[]);
```

C6.6.67 EXTR

Extract register from pair of registers

This instruction is used by the alias ROR (immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0, imms = 0xxxxx)

```
EXTR <Wd>, <Wn>, <Wm>, #<lsb>
```

64-bit variant (sf = 1, N = 1)

```
EXTR <Xd>, <Xn>, <Xm>, #<lsb>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
integer lsb;

if N != sf then UnallocatedEncoding();
if sf == '0' && imms<5> == '1' then ReservedValue();
lsb = UInt(imms);
```

Alias conditions

Alias	is preferred when
ROR (immediate)	`Rn == Rm`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.
`<lsb>`	For the 32-bit variant: is the least significant bit position from which to extract, in the range 0 to 31, encoded in the imms field.
`<lsb>`	For the 64-bit variant: is the least significant bit position from which to extract, in the range 0 to 63, encoded in the imms field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
```

```
bits(2*datasize) concat = operand1:operand2;

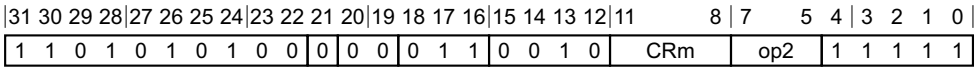
result = concat<lsb+datasize-1:lsb>;

X[d] = result;
```

C6.6.68 HINT

Hint instruction

This instruction is used by the aliases NOP, SEVL, SEV, WFE, WFI, and YIELD. See the *Alias conditions* table for details of when each alias is preferred.



System variant

```
HINT #<imm>

SystemHintOp op;

case CRm:op2 of
    when '0000 000' op = SystemHintOp_NOP;
    when '0000 001' op = SystemHintOp_YIELD;
    when '0000 010' op = SystemHintOp_WFE;
    when '0000 011' op = SystemHintOp_WFI;
    when '0000 100' op = SystemHintOp_SEV;
    when '0000 101' op = SystemHintOp_SEVL;
    otherwise  op = SystemHintOp_NOP;
```

Alias conditions

Alias	is preferred when
NOP	UInt(CRm:op2) == 0
SEVL	UInt(CRm:op2) == 5
SEV	UInt(CRm:op2) == 4
WFE	UInt(CRm:op2) == 2
WFI	UInt(CRm:op2) == 3
YIELD	UInt(CRm:op2) == 1

Assembler symbols

<imm> Is a 7-bit unsigned immediate, in the range 0 to 127, encoded in CRm:op2.

Operation

```
case op of
    when SystemHintOp_YIELD
        Hint_Yield();

    when SystemHintOp_WFE
        if EventRegistered() then
            ClearEventRegister();
        else
            if PSTATE.EL == EL0 then
                AArch64.CheckForWFxTrap(EL1, TRUE);
            if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
                AArch64.CheckForWFxTrap(EL2, TRUE);
```

```
            if HaveEL(EL3) && PSTATE.EL != EL3 then
                AArch64.CheckForWFxTrap(EL3, TRUE);
            WaitForEvent();

        when SystemHintOp_WFI
            if !InterruptPending() then
                if PSTATE.EL == EL0 then
                    AArch64.CheckForWFxTrap(EL1, FALSE);
                if HaveEL(EL2) && !IsSecure() && PSTATE.EL IN {EL0,EL1} then
                    AArch64.CheckForWFxTrap(EL2, FALSE);
                if HaveEL(EL3) && PSTATE.EL != EL3 then
                    AArch64.CheckForWFxTrap(EL3, FALSE);
                WaitForInterrupt();

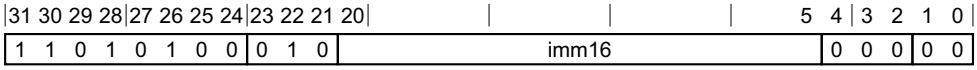
        when SystemHintOp_SEV
            SendEvent();

        when SystemHintOp_SEVL
            EventRegisterSet();

        otherwise // do nothing
```

C6.6.69 HLT

External debug breakpoint



System variant

```
HLT #<imm>
```

```
if EDSCR.HDE == '0' || !HaltingAllowed() then UnallocatedEncoding();
```

Assembler symbols

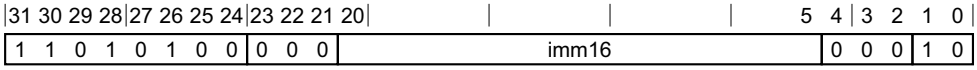
<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.

Operation

```
Halt(DebugHalt_HaltInstruction);
```

C6.6.70 HVC

Generate exception targeting exception level 2



System variant

```
HVC #<imm>

bits(16) imm = imm16;
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.

Operation

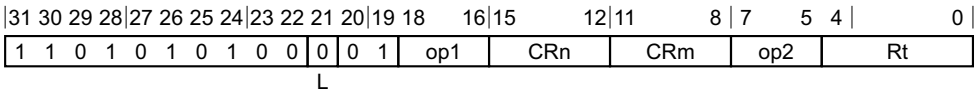
```
if !HaveEL(EL2) || PSTATE.EL == EL0 || (PSTATE.EL == EL1 && IsSecure()) then
    UnallocatedEncoding();

hvc_enable = if HaveEL(EL3) then SCR_EL3.HCE else NOT(HCR_EL2.HCD);
if hvc_enable == '0' then
    UnallocatedEncoding();
else
    AArch64.CallHypervisor(imm);
```

C6.6.71 IC

Instruction cache operation

This instruction is an alias of the SYS instruction.



System variant

`IC <ic_op>{, <Xt>}`

is equivalent to

`SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}`

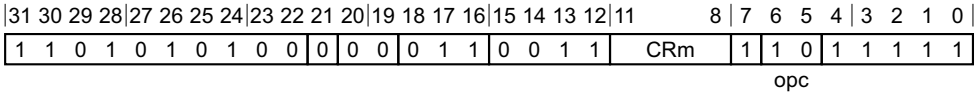
and is the preferred disassembly when `SysOp(op1,CRn,CRm,op2) == Sys_IC`.

Assembler symbols

`<ic_op>`	Is an IC operation name, as listed for the IC system operation pages, encoded in op1:CRn:CRm:op2.
`<op1>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
`<Cn>`	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
`<Cm>`	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
`<op2>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.
`<Xt>`	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the Rt field.

C6.6.72 ISB

Instruction synchronization barrier



System variant

```
ISB {<option>|#<imm>}

MemBarrierOp op;
MBReqDomain domain;
MBReqTypes types;

case opc of
    when '00' op = MemBarrierOp_DSB;
    when '01' op = MemBarrierOp_DMB;
    when '10' op = MemBarrierOp_ISB;
    otherwise UnallocatedEncoding();

case CRm<3:2> of
    when '00' domain = MBReqDomain_OuterShareable;
    when '01' domain = MBReqDomain_Nonshareable;
    when '10' domain = MBReqDomain_InnerShareable;
    when '11' domain = MBReqDomain_FullSystem;

case CRm<1:0> of
    when '01' types = MBReqTypes_Reads;
    when '10' types = MBReqTypes_Writes;
    when '11' types = MBReqTypes_All;
    otherwise
        types = MBReqTypes_All;
        domain = MBReqDomain_FullSystem;
```

Assembler symbols

<option> Is the barrier option name SY, encoded as '1111' in the CRm field.

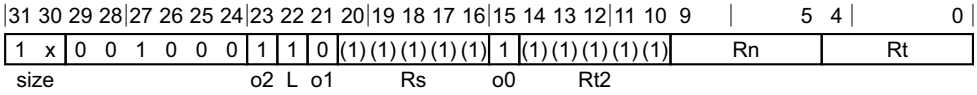
<imm> Is an optional 4-bit unsigned immediate, in the range 0 to 15, defaulting to 15 and encoded in the CRm field.

Operation

```
case op of
    when MemBarrierOp_DSB
        DataSynchronizationBarrier(domain, types);
    when MemBarrierOp_DMB
        DataMemoryBarrier(domain, types);
    when MemBarrierOp_ISB
        InstructionSynchronizationBarrier();
```

C6.6.73 LDAR

Load-acquire register



32-bit variant (size = 10)

```
LDAR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant (size = 11)

```
LDAR <Xt>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

if o2:o1:o0 == '100' || o2:o1:o0 == '11x' then UnallocatedEncoding();
if o1 == '1' && size<1> == '0' then UnallocatedEncoding();

AccType acctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;
boolean excl = (o2 == '0');
boolean pair = (o1 == '1');
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
integer datasize = if pair then elsize * 2 else elsize;
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

Operation

```
bits(64) address;

```

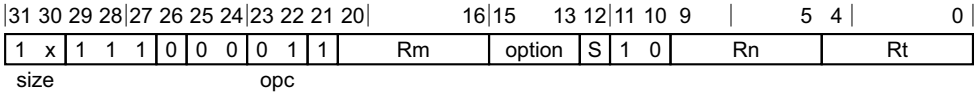
C6.6.85 LDR (register)

Load register (register offset)



32-bit variant (size = 10)

```
LDR <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

64-bit variant (size = 11)

```
LDR <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = `011`

RESERVED when option = `10x`

SXTW when option = `110`

SXTX when option = `111`

`<amount>` For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = `0`

#2 when S = `1`

`<amount>` For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = `0`

#3 when S = 1

Shared decode for all variants

```

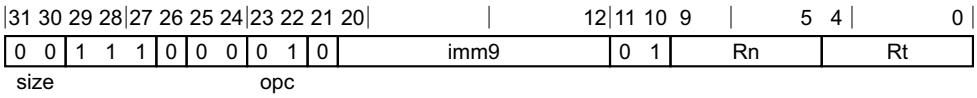
C6.6.86 LDRB (immediate)

Load register byte (immediate offset)

It has encodings from 3 classes:*Post-index*, *Pre-index* and *Unsigned offset*

Post-index

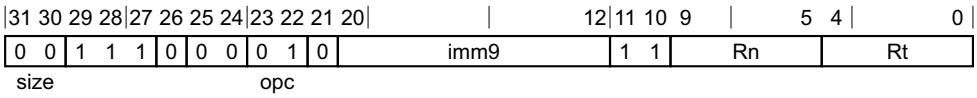


Post-index variant

```
LDRB <Wt>, [<Xn|SP>], #<simm>

boolean wback = TRUE;
boolean postindex = TRUE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Pre-index

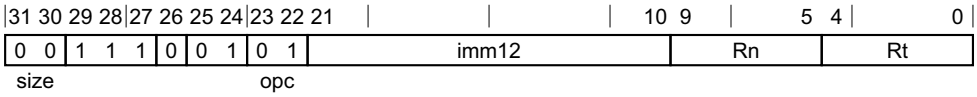


Pre-index variant

```
LDRB <Wt>, [<Xn|SP>, #<simm>]!

boolean wback = TRUE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = SignExtend(imm9, 64);
```

Unsigned offset



Unsigned offset variant

```
LDRB <Wt>, [<Xn|SP>{, #<pimm>}]

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<simm>	Is the signed immediate byte offset, in the range -256 to 255, encoded in the imm9 field.
<pimm>	Is the optional positive immediate byte offset, in the range 0 to 4095, defaulting to 0 and encoded in the imm12 field.

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_NORMAL;
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load
    memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
    regsize = if size == '11' then 64 else 32;

        else
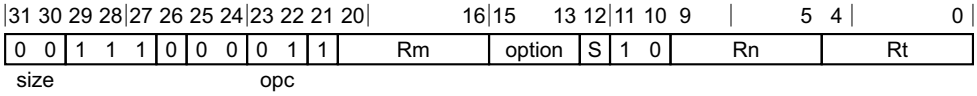
            X[n] = address;
```

C6.6.87 LDRB (register)

Load register byte (register offset)



32-bit variant

```
LDRB <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = `011`

RESERVED when option = `10x`

SXTW when option = `110`

SXTX when option = `111`

`<amount>` Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

[absent] when S = `0`

#0 when S = `1`

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
AccType acctype = AccType_NORMAL;
MemOp memop;
boolean signed;
```

```
integer regsize;

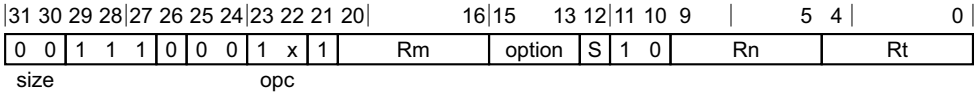
C6.6.91 LDRSB (register)

Load register signed byte (register offset)



32-bit variant (opc = 11)

```
LDRSB <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

64-bit variant (opc = 10)

```
LDRSB <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = `011`

RESERVED when option = `10x`

SXTW when option = `110`

SXTX when option = `111`

`<amount>` Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

[absent] when S = `0`

#0 when S = `1`

Shared decode for all variants

```

```

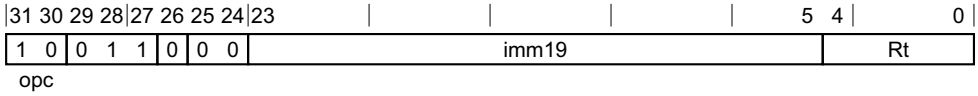
C6.6.95 LDRSW (literal)

Load register signed word (PC-relative literal)



Literal variant

```
LDRSW <Xt>, <label>

integer t = UInt(Rt);
MemOp memop = MemOp_LOAD;
boolean signed = FALSE;
integer size;
bits(64) offset;

case opc of
    when '00'
        size = 4;
    when '01'
        size = 8;
    when '10'
        size = 4;
        signed = TRUE;
    when '11'
        memop = MemOp_PREFETCH;

offset = SignExtend(imm19:'00', 64);
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be loaded, encoded in the Rt field.

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as imm19 times 4.

Operation

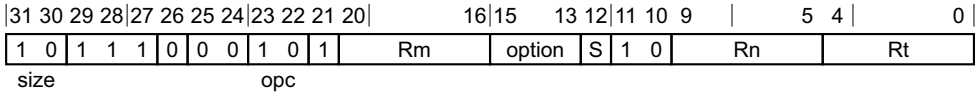
```
bits(64) address = PC[] + offset;
bits(size*8) data;

case memop of
    when MemOp_LOAD
        data = Mem[address, size, AccType_NORMAL];
        if signed then
            X[t] = SignExtend(data, 64);
        else
            X[t] = data;

    when MemOp_PREFETCH
        Prefetch(address, t<4:0>);
```

C6.6.96 LDRSW (register)

Load register signed word (register offset)



64-bit variant

```
LDRSW <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<R> Is the index width specifier, encoded in the option field:

RESERVED when option = 00x

W when option = x10

X when option = x11

RESERVED when option = 10x

<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = 00x

UXTW when option = 010

LSL when option = 011

RESERVED when option = 10x

SXTW when option = 110

SXTX when option = 111

<amount> Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#2 when S = 1

Shared decode for all variants

```
integer n = UInt(Rn);

```

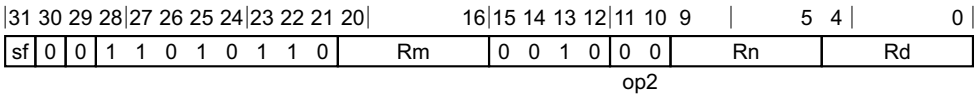
C6.6.113 LSL (register)

Logical shift left (register): `Rd = LSL(Rn, Rm)`

This instruction is an alias of the LSLV instruction.



32-bit variant (sf = 0)

`LSL <Wd>, <Wn>, <Wm>`
is equivalent to
`LSLV <Wd>, <Wn>, <Wm>`
and is always the preferred disassembly.

64-bit variant (sf = 1)

`LSL <Xd>, <Xn>, <Xm>`
is equivalent to
`LSLV <Xd>, <Xn>, <Xm>`
and is always the preferred disassembly.

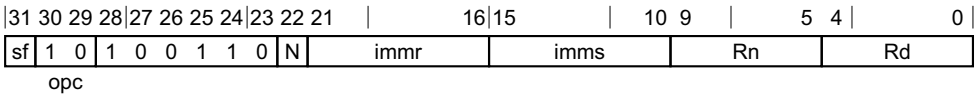
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

C6.6.114 LSL (immediate)

Logical shift left (immediate): `Rd = LSL(Rn, shift)`

This instruction is an alias of the UBFM instruction.



32-bit variant (sf = 0, N = 0)

`LSL <Wd>, <Wn>, #<shift>`

is equivalent to

`UBFM <Wd>, <Wn>, #(-<shift> MOD 32), #(31-<shift>)`

and is the preferred disassembly when `imms != '011111' && imms + 1 == immr`.

64-bit variant (sf = 1, N = 1)

`LSL <Xd>, <Xn>, #<shift>`

is equivalent to

`UBFM <Xd>, <Xn>, #(-<shift> MOD 64), #(63-<shift>)`

and is the preferred disassembly when `imms != '111111' && imms + 1 == immr`.

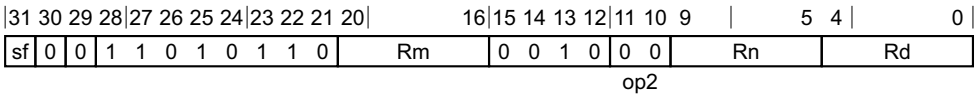
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31.
`<shift>`	For the 64-bit variant: is the shift amount, in the range 0 to 63.

C6.6.115 LSLV

Logical shift left variable: `Rd = LSL(Rn, Rm)`

This instruction is used by the alias LSL (register). The alias is always the preferred disassembly.



32-bit variant (sf = 0)

```
LSLV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
LSLV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

Operation

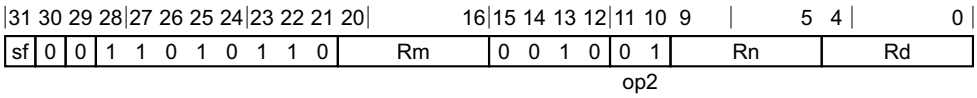
```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

C6.6.116 LSR (register)

Logical shift right (register): `Rd = LSR(Rn, Rm)`

This instruction is an alias of the LSRV instruction.



32-bit variant (sf = 0)

`LSR <Wd>, <Wn>, <Wm>`

is equivalent to

`LSRV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant (sf = 1)

`LSR <Xd>, <Xn>, <Xm>`

is equivalent to

`LSRV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

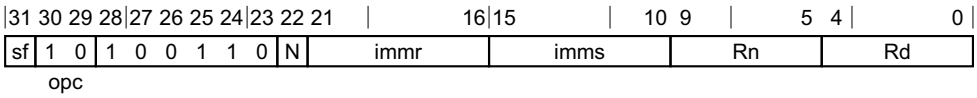
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

C6.6.117 LSR (immediate)

Logical shift right (immediate): `Rd = LSR(Rn, shift)`

This instruction is an alias of the UBFM instruction.



32-bit variant (sf = 0, N = 0)

`LSR <Wd>, <Wn>, #<shift>`

is equivalent to

`UBFM <Wd>, <Wn>, #<shift>, #31`

and is the preferred disassembly when `imms == '011111'`.

64-bit variant (sf = 1, N = 1)

`LSR <Xd>, <Xn>, #<shift>`

is equivalent to

`UBFM <Xd>, <Xn>, #<shift>, #63`

and is the preferred disassembly when `imms == '111111'`.

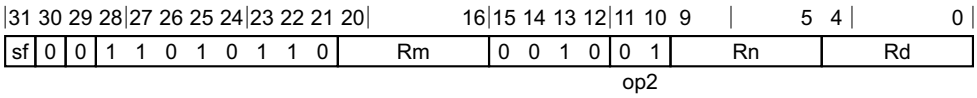
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<shift>`	For the 32-bit variant: is the shift amount, in the range 0 to 31.
`<shift>`	For the 64-bit variant: is the shift amount, in the range 0 to 63.

C6.6.118 LSRV

Logical shift right variable: `Rd = LSR(Rn, Rm)`

This instruction is used by the alias LSR (register). The alias is always the preferred disassembly.



32-bit variant (sf = 0)

```
LSRV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
LSRV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

Operation

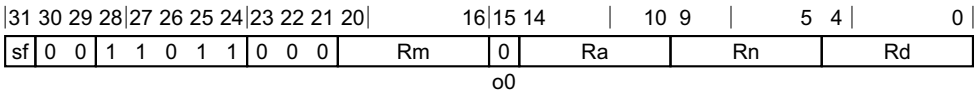
```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

C6.6.119 MADD

Multiply-add: `Rd = Ra + Rn * Rm`

This instruction is used by the alias MUL. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
MADD <Wd>, <Wn>, <Wm>, <Wa>
```

64-bit variant (sf = 1)

```
MADD <Xd>, <Xn>, <Xm>, <Xa>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;
integer datasize = destsize;
boolean sub_op = (o0 == '1');
```

Alias conditions

Alias	is preferred when
MUL	`Ra == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
`<Wa>`	Is the 32-bit name of the third general-purpose source register holding the addend, encoded in the Ra field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
`<Xa>`	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

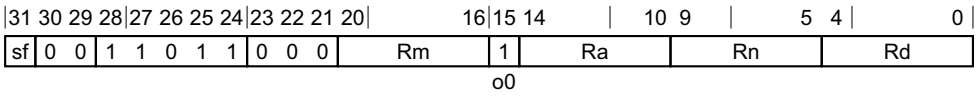
if sub_op then
    result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
else
    result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d] = result<destsize-1:0>;
```

C6.6.120 MNEG

Multiply-negate: `Rd = -(Rn * Rm)`

This instruction is an alias of the MSUB instruction.



32-bit variant (sf = 0)

`MNEG <Wd>, <Wn>, <Wm>`

is equivalent to

`MSUB <Wd>, <Wn>, <Wm>, WZR`

and is the preferred disassembly when `Ra == '11111'`.

64-bit variant (sf = 1)

`MNEG <Xd>, <Xn>, <Xm>`

is equivalent to

`MSUB <Xd>, <Xn>, <Xm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

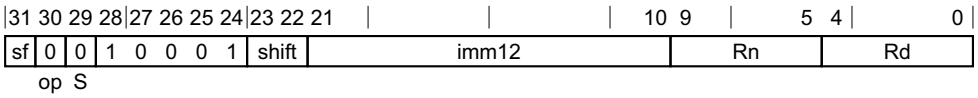
`<Xn>` Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.121 MOV (to/from SP)

Move between register and stack pointer: `Rd = Rn`

This instruction is an alias of the ADD (immediate) instruction.



32-bit variant (sf = 0)

`MOV <Wd|WSP>, <Wn|WSP>`

is equivalent to

`ADD <Wd|WSP>, <Wn|WSP>, #0`

and is the preferred disassembly when `(Rd == '11111' || Rn == '11111') && IsZero(shift:imm12)`.

64-bit variant (sf = 1)

`MOV <Xd|SP>, <Xn|SP>`

is equivalent to

`ADD <Xd|SP>, <Xn|SP>, #0`

and is the preferred disassembly when `(Rd == '11111' || Rn == '11111') && IsZero(shift:imm12)`.

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

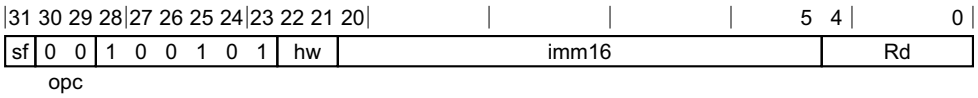
`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

C6.6.122 MOV (inverted wide immediate)

Move inverted 16-bit immediate to register: `Rd = imm`

This instruction is an alias of the MOVN instruction.



32-bit variant (sf = 0)

`MOV <Wd>, #<imm>`

is equivalent to

`MOVN <Wd>, #<imm16>, LSL #<shift>`

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00') && ! IsOnes(imm16)`.

64-bit variant (sf = 1)

`MOV <Xd>, #<imm>`

is equivalent to

`MOVN <Xd>, #<imm16>, LSL #<shift>`

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

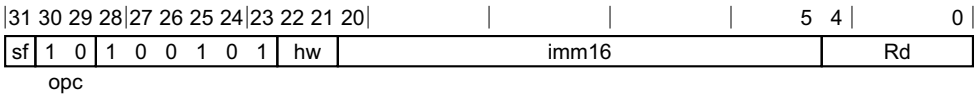
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<imm>`	For the 32-bit variant: is a 32-bit immediate, the bitwise inverse of which can be encoded in imm16:hw, but excluding 0xffff0000 and 0x0000ffff
`<imm>`	For the 64-bit variant: is a 64-bit immediate, the bitwise inverse of which can be encoded in imm16:hw.
`<imm16>`	Is the computed 16-bit immediate which, together with <shift>, encodes NOT(<imm>).
`<shift>`	For the 32-bit variant: is the computed minimum left shift of 0 or 16 which applied to <imm16> will encode the value of NOT(<imm>).
`<shift>`	For the 64-bit variant: is the computed minimum left shift of 0, 16, 32 or 48 which applied to <imm16> will encode the value of NOT(<imm>).

C6.6.123 MOV (wide immediate)

Move 16-bit immediate to register: `Rd = imm`

This instruction is an alias of the MOVZ instruction.



32-bit variant (sf = 0)

`MOV <Wd>, #<imm>`

is equivalent to

`MOVZ <Wd>, #<imm16>, LSL #<shift>`

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

64-bit variant (sf = 1)

`MOV <Xd>, #<imm>`

is equivalent to

`MOVZ <Xd>, #<imm16>, LSL #<shift>`

and is the preferred disassembly when `!(IsZero(imm16) && hw != '00')`.

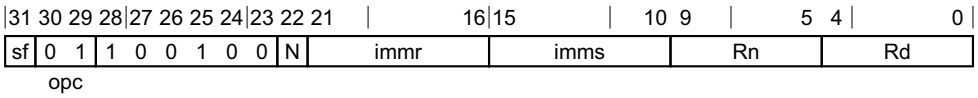
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<imm>`	For the 32-bit variant: is a 32-bit immediate which can be encoded in imm16:hw.
`<imm>`	For the 64-bit variant: is a 64-bit immediate which can be encoded in imm16:hw.
`<imm16>`	Is the computed 16-bit immediate which, together with <shift>, encodes <imm>.
`<shift>`	For the 32-bit variant: is the computed minimum left shift of 0 or 16 which applied to <imm16> will encode the value of <imm>.
`<shift>`	For the 64-bit variant: is the computed minimum left shift of 0, 16, 32 or 48 which applied to <imm16> will encode the value of <imm>.

C6.6.124 MOV (bitmask immediate)

Move bitmask immediate to register: `Rd = imm`

This instruction is an alias of the ORR (immediate) instruction.



32-bit variant (sf = 0, N = 0)

```
MOV <Wd|WSP>, #<imm>
```

is equivalent to

```
ORR <Wd|WSP>, WZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

64-bit variant (sf = 1)

```
MOV <Xd|SP>, #<imm>
```

is equivalent to

```
ORR <Xd|SP>, XZR, #<imm>
```

and is the preferred disassembly when `!MoveWidePreferred(sf, N, imms, immr)`.

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

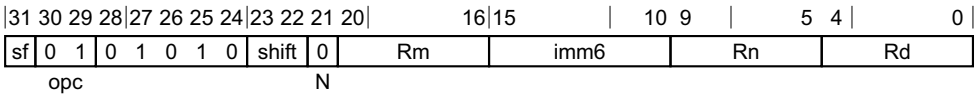
`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<imm>` Is the bitmask immediate, encoded in N:imms:immr, but excluding values which could be encoded by MOVZ or MOVN.

C6.6.125 MOV (register)

Move register to register: `Rd = Rm`

This instruction is an alias of the ORR (shifted register) instruction.



32-bit variant (sf = 0)

`MOV <Wd>, <Wm>`

is equivalent to

`ORR <Wd>, WZR, <Wm>`

and is the preferred disassembly when `Rn == '11111' && IsZero(shift:imm6)`.

64-bit variant (sf = 1)

`MOV <Xd>, <Xm>`

is equivalent to

`ORR <Xd>, XZR, <Xm>`

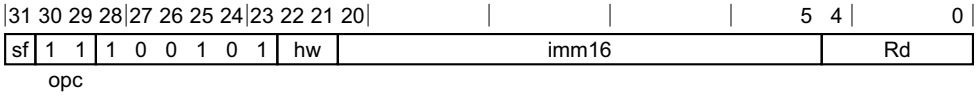
and is the preferred disassembly when `Rn == '11111' && IsZero(shift:imm6)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wm>`	Is the 32-bit name of the general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xm>`	Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

C6.6.126 MOVK

Move 16-bit immediate into register, keeping other bits unchanged: `Rd<shift+15:shift> = imm16`



32-bit variant (sf = 0)

```
MOVK <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant (sf = 1)

```
MOVK <Xd>, #<imm>{, LSL #<shift>}

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
bits(16) imm = imm16;
integer pos;
MoveWideOp opcode;

case opc of
    when '00' opcode = MoveWideOp_N;
    when '10' opcode = MoveWideOp_Z;
    when '11' opcode = MoveWideOp_K;
    otherwise UnallocatedEncoding();

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<imm>	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.
<shift>	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the hw field as <shift>/16.
<shift>	For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the hw field as <shift>/16.

Operation

```
bits(datasize) result;

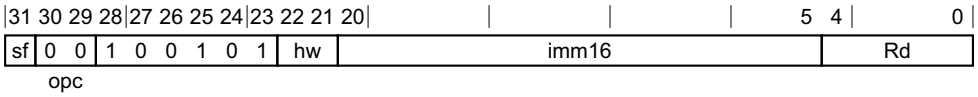
if opcode == MoveWideOp_K then
    result = X[d];
else
    result = Zeros();

result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
```

C6.6.127 MOVN

Move inverse of shifted 16-bit immediate to register: `Rd = NOT (LSL (imm16, shift))`

This instruction is used by the alias MOV (inverted wide immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
MOVN <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant (sf = 1)

```
MOVN <Xd>, #<imm>{, LSL #<shift>}
```

```
integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
bits(16) imm = imm16;
integer pos;
MoveWideOp opcode;

case opc of
    when '00' opcode = MoveWideOp_N;
    when '10' opcode = MoveWideOp_Z;
    when '11' opcode = MoveWideOp_K;
    otherwise UnallocatedEncoding();

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Alias conditions

Alias	of variant	is preferred when
MOV (inverted wide immediate)	64-bit	`! (IsZero(imm16) && hw != '00')`
MOV (inverted wide immediate)	32-bit	`! (IsZero(imm16) && hw != '00') && ! IsOnes(imm16)`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<imm>`	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.
`<shift>`	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the hw field as <shift>/16.
`<shift>`	For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the hw field as <shift>/16.

Operation

```
bits(datasize) result;

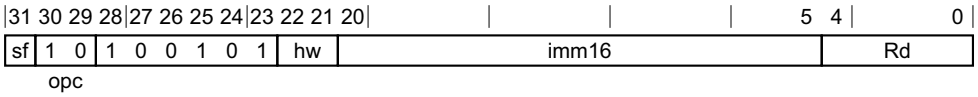
if opcode == MoveWideOp_K then
    result = X[d];
else
    result = Zeros();

result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
```

C6.6.128 MOVZ

Move shifted 16-bit immediate to register: `Rd = LSL (imm16, shift)`

This instruction is used by the alias MOV (wide immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
MOVZ <Wd>, #<imm>{, LSL #<shift>}
```

64-bit variant (sf = 1)

```
MOVZ <Xd>, #<imm>{, LSL #<shift>}

integer d = UInt(Rd);
integer datasize = if sf == '1' then 64 else 32;
bits(16) imm = imm16;
integer pos;
MoveWideOp opcode;

case opc of
    when '00' opcode = MoveWideOp_N;
    when '10' opcode = MoveWideOp_Z;
    when '11' opcode = MoveWideOp_K;
    otherwise UnallocatedEncoding();

if sf == '0' && hw<1> == '1' then UnallocatedEncoding();
pos = UInt(hw:'0000');
```

Alias conditions

Alias	is preferred when
MOV (wide immediate)	`! (IsZero(imm16) && hw != '00')`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<imm>`	Is the 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.
`<shift>`	For the 32-bit variant: is the amount by which to shift the immediate left, either 0 (the default) or 16, encoded in the hw field as <shift>/16.
`<shift>`	For the 64-bit variant: is the amount by which to shift the immediate left, either 0 (the default), 16, 32 or 48, encoded in the hw field as <shift>/16.

Operation

```
bits(datasize) result;

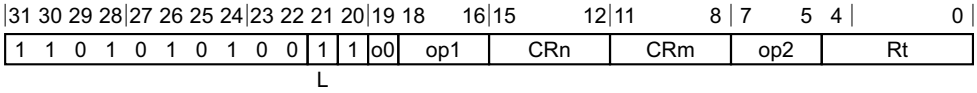
if opcode == MoveWideOp_K then
    result = X[d];
```

```
else
    result = Zeros();

result<pos+15:pos> = imm;
if opcode == MoveWideOp_N then
    result = NOT(result);
X[d] = result;
```

C6.6.129 MRS

Move from system register



System variant

```
MRS <Xt>, <systemreg>

CheckSystemAccess(op1);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
boolean read = (L == '1');
```

Assembler symbols

<Xt> Is the 64-bit name of the general-purpose destination register, encoded in the Rt field.

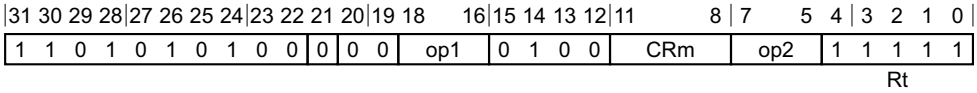
<systemreg> Is a system register name, encoded in the o0:op1:CRn:CRm:op2.

Operation

```
if read then
    X[t] = System_Get(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
else
    System_Put(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

C6.6.130 MSR (immediate)

Move immediate to processor state field



System variant

```
MSR <pstatefield>, #<imm>

CheckSystemAccess(op1);

// Check that an AArch64 MSR/MRS access to the DAIF flags is permitted
if op1 == '011' && PSTATE.EL == EL0 && SCTLR_EL1.UMA == '0' then
    AArch64.SystemRegisterTrap(EL1, '00', op2, op1, '0100', Rt, CRm, '0');

bits(4) operand = CRm;
PSTATEField field;
case op1:op2 of
    when '000 101' field = PSTATEField_SP;
    when '011 110' field = PSTATEField_DAIFSet;
    when '011 111' field = PSTATEField_DAIFClr;
    otherwise      UnallocatedEncoding();
```

Assembler symbols

<pstatefield> Is a PSTATE field name, encoded in the op1:op2 field:

RESERVED when op1 = 000, op2 = 0xx

RESERVED when op1 = 000, op2 = 100

SPSel when op1 = 000, op2 = 101

RESERVED when op1 = 000, op2 = 11x

RESERVED when op1 = 001, op2 = xxx

RESERVED when op1 = 010, op2 = xxx

RESERVED when op1 = 011, op2 = 0xx

RESERVED when op1 = 011, op2 = 10x

DAIFSet when op1 = 011, op2 = 110

DAIFClr when op1 = 011, op2 = 111

RESERVED when op1 = 1xx, op2 = xxx

<imm> Is a 4-bit unsigned immediate, in the range 0 to 15, encoded in the CRm field.

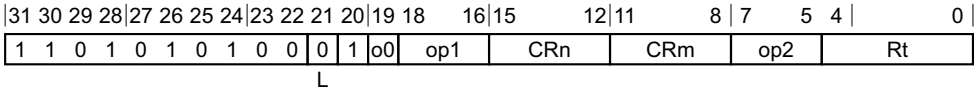
Operation

```
case field of
    when PSTATEField_SP
        PSTATE.SP = operand<0>;
    when PSTATEField_DAIFSet
        PSTATE.D = PSTATE.D OR operand<3>;
        PSTATE.A = PSTATE.A OR operand<2>;
        PSTATE.I = PSTATE.I OR operand<1>;
        PSTATE.F = PSTATE.F OR operand<0>;
    when PSTATEField_DAIFClr
        PSTATE.D = PSTATE.D AND NOT(operand<3>);
```

```
PSTATE.A = PSTATE.A AND NOT(operand<2>);
PSTATE.I = PSTATE.I AND NOT(operand<1>);
PSTATE.F = PSTATE.F AND NOT(operand<0>);
```

C6.6.131 MSR (register)

Move to system register



System variant

```
MSR <systemreg>, <Xt>

CheckSystemAccess(op1);

integer t = UInt(Rt);

integer sys_op0 = 2 + UInt(o0);
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
boolean read = (L == '1');
```

Assembler symbols

`<systemreg>` Is a system register name, encoded in the o0:op1:CRn:CRm:op2.

`<Xt>` Is the 64-bit name of the general-purpose source register, encoded in the Rt field.

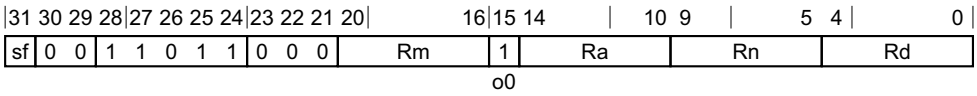
Operation

```
if read then
    X[t] = System_Get(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
else
    System_Put(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

C6.6.132 MSUB

Multiply-subtract: `Rd = Ra - Rn * Rm`

This instruction is used by the alias MNEG. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
MSUB <Wd>, <Wn>, <Wm>, <Wa>
```

64-bit variant (sf = 1)

```
MSUB <Xd>, <Xn>, <Xm>, <Xa>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = if sf == '1' then 64 else 32;
integer datasize = destsize;
boolean sub_op = (o0 == '1');
```

Alias conditions

Alias	is preferred when
MNEG	`Ra == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
`<Wa>`	Is the 32-bit name of the third general-purpose source register holding the minuend, encoded in the Ra field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
`<Xa>`	Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

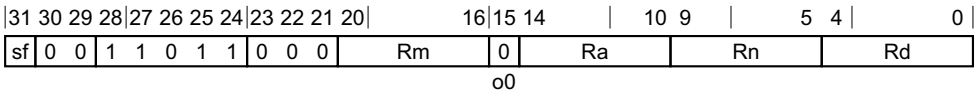
if sub_op then
    result = UInt(operand3) - (UInt(operand1) * UInt(operand2));
else
    result = UInt(operand3) + (UInt(operand1) * UInt(operand2));

X[d] = result<destsize-1:0>;
```

C6.6.133 MUL

Multiply: `Rd = Rn * Rm`

This instruction is an alias of the MADD instruction.



32-bit variant (sf = 0)

`MUL <Wd>, <Wn>, <Wm>`

is equivalent to

`MADD <Wd>, <Wn>, <Wm>, WZR`

and is the preferred disassembly when `Ra == '11111'`.

64-bit variant (sf = 1)

`MUL <Xd>, <Xn>, <Xm>`

is equivalent to

`MADD <Xd>, <Xn>, <Xm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

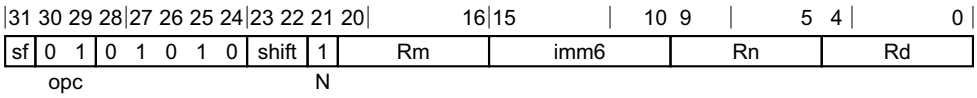
`<Xn>` Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.134 MVN

Bitwise NOT (shifted register): `Rd = NOT shift(Rm, amount)`

This instruction is an alias of the ORN (shifted register) instruction.



32-bit variant (sf = 0)

```
MVN <Wd>, <Wm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Wd>, WZR, <Wm>{, <shift> #<amount>}
```

and is the preferred disassembly when `Rn == '11111'`.

64-bit variant (sf = 1)

```
MVN <Xd>, <Xm>{, <shift> #<amount>}
```

is equivalent to

```
ORN <Xd>, XZR, <Xm>{, <shift> #<amount>}
```

and is the preferred disassembly when `Rn == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

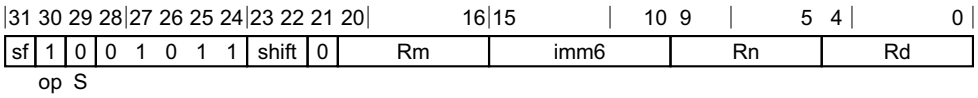
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,

C6.6.135 NEG

Negate: `Rd = 0 - shift(Rm, amount)`

This instruction is an alias of the SUB (shifted register) instruction.



32-bit variant (sf = 0)

`NEG <Wd>, <Wm>{, <shift> #<amount>}`

is equivalent to

`SUB <Wd>, WZR, <Wm> {, <shift> #<amount>}`

and is the preferred disassembly when `Rn == '11111'`.

64-bit variant (sf = 1)

`NEG <Xd>, <Xm>{, <shift> #<amount>}`

is equivalent to

`SUB <Xd>, XZR, <Xm> {, <shift> #<amount>}`

and is the preferred disassembly when `Rn == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = `11`

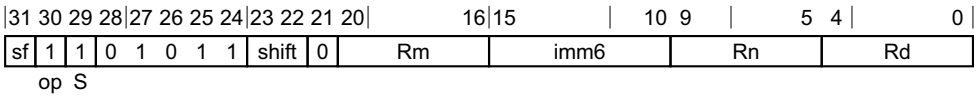
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

C6.6.136 NEGS

Negate, setting the condition flags: `Rd = 0 - shift(Rm, amount)`

This instruction is an alias of the SUBS (shifted register) instruction.



32-bit variant (sf = 0)

`NEGS <Wd>, <Wm>{, <shift> #<amount>}`

is equivalent to

`SUBS <Wd>, WZR, <Wm> {, <shift> #<amount>}`

and is the preferred disassembly when `Rn == '11111'`.

64-bit variant (sf = 1)

`NEGS <Xd>, <Xm>{, <shift> #<amount>}`

is equivalent to

`SUBS <Xd>, XZR, <Xm> {, <shift> #<amount>}`

and is the preferred disassembly when `Rn == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = `11`

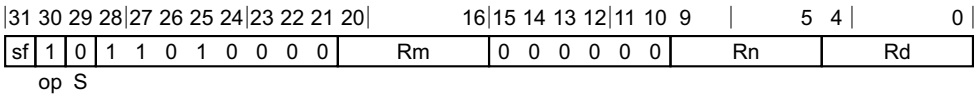
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

C6.6.137 NGC

Negate with carry: `Rd = 0 - Rm - 1 + C`

This instruction is an alias of the SBC instruction.



32-bit variant (sf = 0)

`NGC <Wd>, <Wm>`

is equivalent to

`SBC <Wd>, WZR, <Wm>`

and is the preferred disassembly when `Rn == '11111'`.

64-bit variant (sf = 1)

`NGC <Xd>, <Xm>`

is equivalent to

`SBC <Xd>, XZR, <Xm>`

and is the preferred disassembly when `Rn == '11111'`.

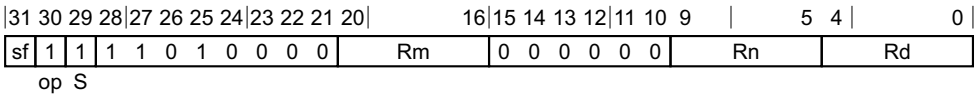
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wm>`	Is the 32-bit name of the general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xm>`	Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

C6.6.138 NGCS

Negate with carry, setting the condition flags: `Rd = 0 - Rm - 1 + C`

This instruction is an alias of the SBCS instruction.



32-bit variant (sf = 0)

`NGCS <Wd>, <Wm>`

is equivalent to

`SBCS <Wd>, WZR, <Wm>`

and is the preferred disassembly when `Rn == '11111'`.

64-bit variant (sf = 1)

`NGCS <Xd>, <Xm>`

is equivalent to

`SBCS <Xd>, XZR, <Xm>`

and is the preferred disassembly when `Rn == '11111'`.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wm>` Is the 32-bit name of the general-purpose source register, encoded in the Rm field.

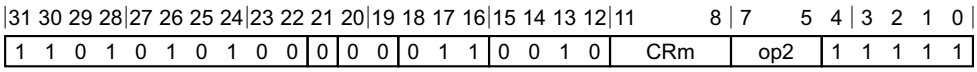
`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xm>` Is the 64-bit name of the general-purpose source register, encoded in the Rm field.

C6.6.139 NOP

No operation

This instruction is an alias of the HINT instruction.



System variant

`NOP`

is equivalent to

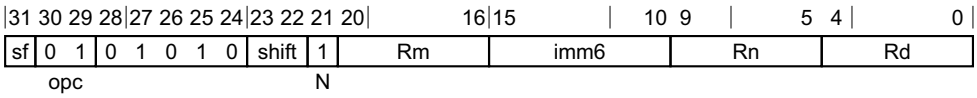
`HINT #0`

and is the preferred disassembly when `UInt(CRm:op2) == 0`.

C6.6.140 ORN (shifted register)

Bitwise inclusive OR NOT (shifted register): `Rd = Rn OR NOT shift(Rm, amount)`

This instruction is used by the alias MVN. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ORN <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
ORN <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Alias conditions

Alias	is preferred when
MVN	`Rn == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

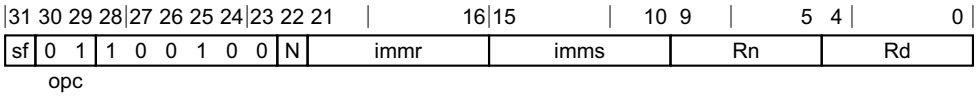
if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.141 ORR (immediate)

Bitwise inclusive OR (immediate): `Rd = Rn OR imm`

This instruction is used by the alias MOV (bitmask immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0)

```
ORR <Wd|WSP>, <Wn>, #<imm>
```

64-bit variant (sf = 1)

```
ORR <Xd|SP>, <Xn>, #<imm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

bits(datasize) imm;
if sf == '0' && N != '0' then ReservedValue();
(imm, -) = DecodeBitMasks(N, imms, immr, TRUE);
```

Alias conditions

Alias	is preferred when
MOV (bitmask immediate)	`! MoveWidePreferred(sf, N, imms, immr)`

Assembler symbols

`<Wd|WSP>`	Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd|SP>`	Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<imm>`	Is the bitmask immediate, encoded in N:imms:immr.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = imm;
```

```
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

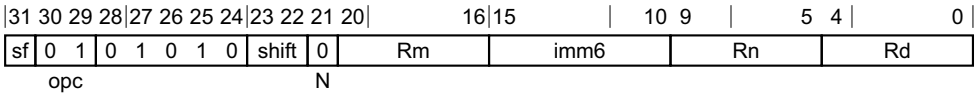
if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.142 ORR (shifted register)

Bitwise inclusive OR (shifted register): `Rd = Rn OR shift(Rm, amount)`

This instruction is used by the alias MOV (register). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
ORR <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
ORR <Xd>, <Xn>, <Xm>{, <shift> #<amount>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean setflags;
LogicalOp op;
case opc of
    when '00' op = LogicalOp_AND; setflags = FALSE;
    when '01' op = LogicalOp_ORR; setflags = FALSE;
    when '10' op = LogicalOp_EOR; setflags = FALSE;
    when '11' op = LogicalOp_AND; setflags = TRUE;

if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
boolean invert = (N == '1');
```

Alias conditions

Alias	is preferred when
MOV (register)	`Rn == '11111' && IsZero(shift:imm6)`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = 10

ROR when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);

if invert then operand2 = NOT(operand2);

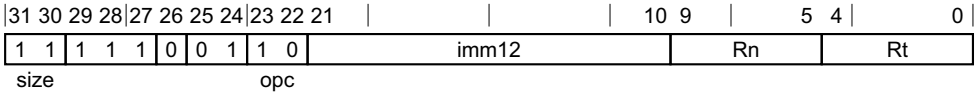
case op of
    when LogicalOp_AND result = operand1 AND operand2;
    when LogicalOp_ORR result = operand1 OR  operand2;
    when LogicalOp_EOR result = operand1 EOR operand2;

if setflags then
    PSTATE.<N,Z,C,V> = result<datasize-1>:IsZeroBit(result):'00';

X[d] = result;
```

C6.6.143 PRFM (immediate)

Prefetch memory (immediate offset)



Unsigned offset variant

```
PRFM <prfop>, [<Xn|SP>{, #<pimm>}]

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
bits(64) offset = LSL(ZeroExtend(imm12, 64), scale);
```

Assembler symbols

<prfop> Is the prefetch operation, encoded in the Rt field:

PLDL1KEEP when Rt = 00000

PLDL1STRM when Rt = 00001

PLDL2KEEP when Rt = 00010

PLDL2STRM when Rt = 00011

PLDL3KEEP when Rt = 00100

PLDL3STRM when Rt = 00101

#uimm5 when Rt = 0011x

PLIL1KEEP when Rt = 01000

PLIL1STRM when Rt = 01001

PLIL2KEEP when Rt = 01010

PLIL2STRM when Rt = 01011

PLIL3KEEP when Rt = 01100

PLIL3STRM when Rt = 01101

#uimm5 when Rt = 0111x

PSTL1KEEP when Rt = 10000

PSTL1STRM when Rt = 10001

PSTL2KEEP when Rt = 10010

PSTL2STRM when Rt = 10011

PSTL3KEEP when Rt = 10100

PSTL3STRM when Rt = 10101

#uimm5 when Rt = 1011x

#uimm5 when Rt = 11xxx

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<pimm> Is the optional positive immediate byte offset, a multiple of 8 in the range 0 to 32760, defaulting to 0 and encoded in the imm12 field as <pimm>/8.

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_NORMAL;
MemOp memop;
boolean signed;
integer regsize;

if opc<1> == '0' then
    // store or zero-extending load

PSTL3KEEP when Rt = 10100

PSTL3STRM when Rt = 10101

#uimm5 when Rt = 1011x

#uimm5 when Rt = 11xxx

<label> Is the program label from which the data is to be loaded. Its offset from the address of this instruction, in the range +/-1MB, is encoded as imm19 times 4.

Operation

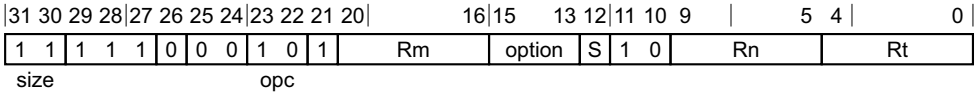
```
bits(64) address = PC[] + offset;
bits(size*8) data;

case memop of
    when MemOp_LOAD
        data = Mem[address, size, AccType_NORMAL];
        if signed then
            X[t] = SignExtend(data, 64);
        else
            X[t] = data;

    when MemOp_PREFETCH
        Prefetch(address, t<4:0>);
```

C6.6.145 PRFM (register)

Prefetch memory (register offset)



Integer variant

```
PRFM <prfop>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]

boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

<prfop> Is the prefetch operation, encoded in the Rt field:

PLDL1KEEP when Rt = 00000

PLDL1STRM when Rt = 00001

PLDL2KEEP when Rt = 00010

PLDL2STRM when Rt = 00011

PLDL3KEEP when Rt = 00100

PLDL3STRM when Rt = 00101

PSTL3KEEP when Rt = 10100

PSTL3STRM when Rt = 10101

#uimm5 when Rt = 1011x

#uimm5 when Rt = 11xxx

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<R> Is the index width specifier, encoded in the option field:

RESERVED when option = 00x

W when option = x10

X when option = x11

RESERVED when option = 10x

<m> Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

<extend> Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = 00x

UXTW when option = 010

LSL when option = 011

RESERVED when option = 10x

SXTW when option = 110

SXTX when option = 111

<amount> Is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#3 when S = 1

Shared decode for all variants

```
integer n = UInt(Rn);

```

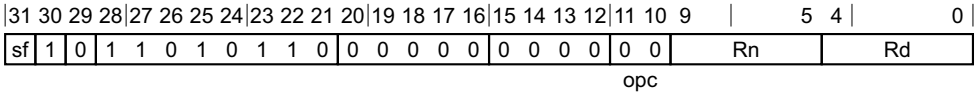
C6.6.147 RBIT

Reverse bit order



32-bit variant (sf = 0)

```
RBIT <Wd>, <Wn>
```

64-bit variant (sf = 1)

```
RBIT <Xd>, <Xn>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

RevOp op;
case opc of
    when '00'
        op = RevOp_RBIT;
    when '01'
        op = RevOp_REV16;
    when '10'
        op = RevOp_REV32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        op = RevOp_REV64;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

```
bits(datasize) result;
bits(6) V;
integer vbit;

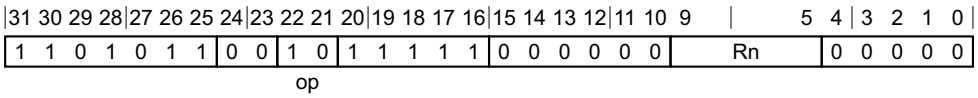
case op of
    when RevOp_REV16 V = '001000';
    when RevOp_REV32 V = '011000';
    when RevOp_REV64 V = '111000';
    when RevOp_RBIT  V = if datasize == 64 then '111111' else '011111';

result = X[n];
for vbit = 0 to 5
    // Swap pairs of 2^vbit bits in result
    if V<vbit> == '1' then
        bits(datasize) tmp = result;
        integer vsize = 1 << vbit;
        integer base = 0;
        while base < datasize do
```

```
                result<base+vsize-1:base> = tmp<base+(2*vsize)-1:base+vsize>;
                result<base+(2*vsize)-1:base+vsize> = tmp<base+vsize-1:base>;
                base = base + (2 * vsize);
        X[d] = result;
```

C6.6.148 RET

Return from subroutine, branches unconditionally to an address in a register, with a hint that this is a subroutine return



Integer variant

```
RET {<Xn>}

integer n = UInt(Rn);
BranchType branch_type;

case op of
    when '00' branch_type = BranchType_JMP;
    when '01' branch_type = BranchType_CALL;
    when '10' branch_type = BranchType_RET;
    otherwise UnallocatedEncoding();
```

Assembler symbols

<Xn> Is the 64-bit name of the general-purpose register holding the address to be branched to, encoded in the Rn field. Defaults to X30 if absent.

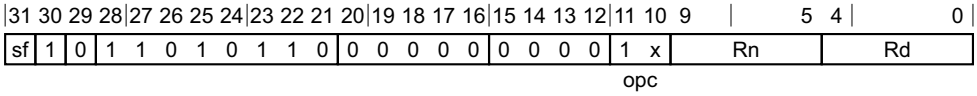
Operation

```
bits(64) target = X[n];

if branch_type == BranchType_CALL then X[30] = PC[] + 4;
BranchTo(target, branch_type);
```

C6.6.149 REV

Reverse bytes



32-bit variant (sf = 0, opc = 10)

```
REV <Wd>, <Wn>
```

64-bit variant (sf = 1, opc = 11)

```
REV <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

RevOp op;
case opc of
    when '00'
        op = RevOp_RBIT;
    when '01'
        op = RevOp_REV16;
    when '10'
        op = RevOp_REV32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        op = RevOp_REV64;
```

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

<Wn> Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

```
bits(datasize) result;
bits(6) V;
integer vbit;

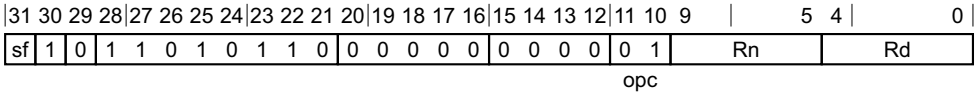
case op of
    when RevOp_REV16 V = '001000';
    when RevOp_REV32 V = '011000';
    when RevOp_REV64 V = '111000';
    when RevOp_RBIT  V = if datasize == 64 then '111111' else '011111';

result = X[n];
for vbit = 0 to 5
    // Swap pairs of 2^vbit bits in result
    if V<vbit> == '1' then
        bits(datasize) tmp = result;
        integer vsize = 1 << vbit;
        integer base = 0;
        while base < datasize do
```

```
            result<base+vsize-1:base> = tmp<base+(2*vsize)-1:base+vsize>;
            result<base+(2*vsize)-1:base+vsize> = tmp<base+vsize-1:base>;
            base = base + (2 * vsize);
X[d] = result;
```

C6.6.150 REV16

Reverse bytes in 16-bit halfwords



32-bit variant (sf = 0)

```
REV16 <Wd>, <Wn>
```

64-bit variant (sf = 1)

```
REV16 <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

RevOp op;
case opc of
    when '00'
        op = RevOp_RBIT;
    when '01'
        op = RevOp_REV16;
    when '10'
        op = RevOp_REV32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        op = RevOp_REV64;
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
<Wn>	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Xn>	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

```
bits(datasize) result;
bits(6) V;
integer vbit;

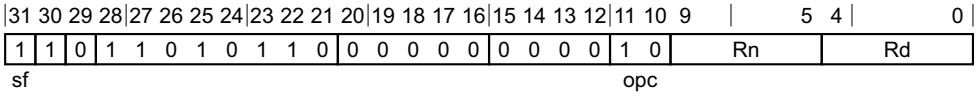
case op of
    when RevOp_REV16 V = '001000';
    when RevOp_REV32 V = '011000';
    when RevOp_REV64 V = '111000';
    when RevOp_RBIT  V = if datasize == 64 then '111111' else '011111';

result = X[n];
for vbit = 0 to 5
    // Swap pairs of 2^vbit bits in result
    if V<vbit> == '1' then
        bits(datasize) tmp = result;
        integer vsize = 1 << vbit;
        integer base = 0;
        while base < datasize do
```

```
            result<base+vsize-1:base> = tmp<base+(2*vsize)-1:base+vsize>;
            result<base+(2*vsize)-1:base+vsize> = tmp<base+vsize-1:base>;
            base = base + (2 * vsize);
X[d] = result;
```

C6.6.151 REV32

Reverse bytes in 32-bit words



64-bit variant

```
REV32 <Xd>, <Xn>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize = if sf == '1' then 64 else 32;

RevOp op;
case opc of
    when '00'
        op = RevOp_RBIT;
    when '01'
        op = RevOp_REV16;
    when '10'
        op = RevOp_REV32;
    when '11'
        if sf == '0' then UnallocatedEncoding();
        op = RevOp_REV64;
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Xn> Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

Operation

```
bits(datasize) result;
bits(6) V;
integer vbit;

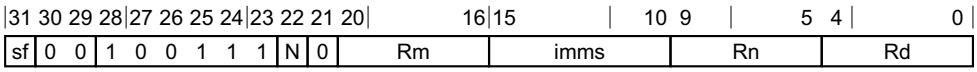
case op of
    when RevOp_REV16 V = '001000';
    when RevOp_REV32 V = '011000';
    when RevOp_REV64 V = '111000';
    when RevOp_RBIT  V = if datasize == 64 then '111111' else '011111';

result = X[n];
for vbit = 0 to 5
    // Swap pairs of 2^vbit bits in result
    if V<vbit> == '1' then
        bits(datasize) tmp = result;
        integer vsize = 1 << vbit;
        integer base = 0;
        while base < datasize do
            result<base+vsize-1:base> = tmp<base+(2*vsize)-1:base+vsize>;
            result<base+(2*vsize)-1:base+vsize> = tmp<base+vsize-1:base>;
            base = base + (2 * vsize);
X[d] = result;
```

C6.6.152 ROR (immediate)

Rotate right (immediate): `Rd = ROR(Rs, shift)`

This instruction is an alias of the EXTR instruction.



32-bit variant (sf = 0, N = 0, imms = 0xxxxx)

`ROR <Wd>, <Ws>, #<shift>`

is equivalent to

`EXTR <Wd>, <Ws>, <Ws>, #<shift>`

and is the preferred disassembly when `Rn == Rm`.

64-bit variant (sf = 1, N = 1)

`ROR <Xd>, <Xs>, #<shift>`

is equivalent to

`EXTR <Xd>, <Xs>, <Xs>, #<shift>`

and is the preferred disassembly when `Rn == Rm`.

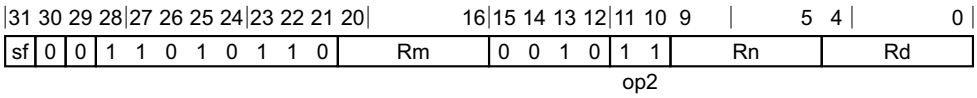
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Ws>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xs>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn and Rm fields.
`<shift>`	For the 32-bit variant: is the amount by which to rotate, in the range 0 to 31, encoded in the imms field.
`<shift>`	For the 64-bit variant: is the amount by which to rotate, in the range 0 to 63, encoded in the imms field.

C6.6.153 ROR (register)

Rotate right (register): `Rd = ROR(Rn, Rm)`

This instruction is an alias of the RORV instruction.



32-bit variant (sf = 0)

`ROR <Wd>, <Wn>, <Wm>`

is equivalent to

`RORV <Wd>, <Wn>, <Wm>`

and is always the preferred disassembly.

64-bit variant (sf = 1)

`ROR <Xd>, <Xn>, <Xm>`

is equivalent to

`RORV <Xd>, <Xn>, <Xm>`

and is always the preferred disassembly.

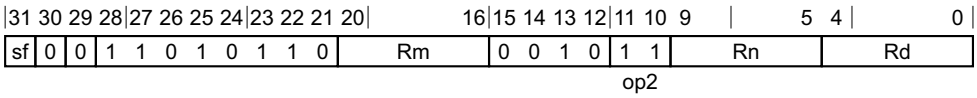
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

C6.6.154 RORV

Rotate right variable: `Rd = ROR(Rn, Rm)`

This instruction is used by the alias ROR (register). The alias is always the preferred disassembly.



32-bit variant (sf = 0)

```
RORV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
RORV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
ShiftType shift_type = DecodeShift(op2);
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register holding a shift amount from 0 to 31 in its bottom 5 bits, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register holding a shift amount from 0 to 63 in its bottom 6 bits, encoded in the Rm field.

Operation

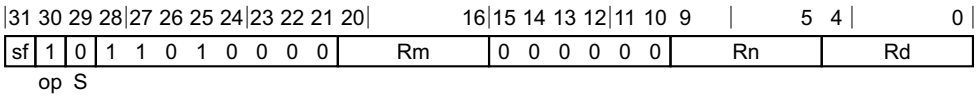
```
bits(datasize) result;
bits(datasize) operand2 = X[m];

result = ShiftReg(n, shift_type, UInt(operand2) MOD datasize);
X[d] = result;
```

C6.6.155 SBC

Subtract with carry: `Rd = Rn - Rm - 1 + C`

This instruction is used by the alias NGC. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SBC <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
SBC <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

Alias conditions

Alias	is preferred when
NGC	`Rn == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

if sub_op then
    operand2 = NOT(operand2);

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

if setflags then
```

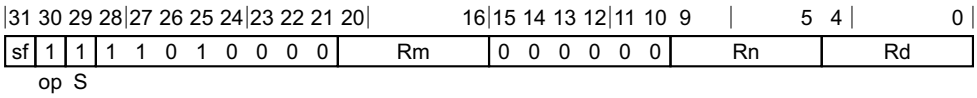
```
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.156 SBCS

Subtract with carry, setting the condition flags: `Rd = Rn - Rm - 1 + C`

This instruction is used by the alias NGCS. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SBCS <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
SBCS <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
```

Alias conditions

Alias	is preferred when
NGCS	`Rn == '11111'`

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(4) nzcv;

if sub_op then
    operand2 = NOT(operand2);

(result, nzcv) = AddWithCarry(operand1, operand2, PSTATE.C);

if setflags then
```

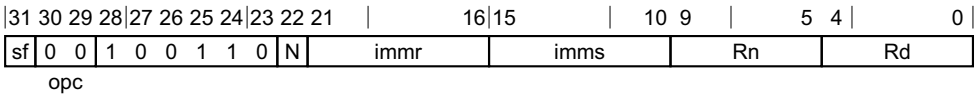
```
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.157 SBFIZ

Signed bitfield insert in zero, with sign replication to left and zeros to right

This instruction is an alias of the SBFM instruction.



32-bit variant (sf = 0, N = 0)

`SBFIZ <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant (sf = 1, N = 1)

`SBFIZ <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

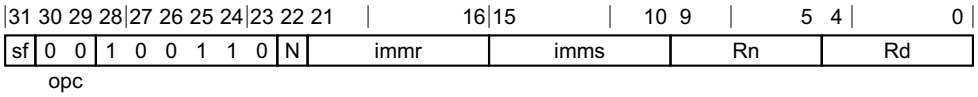
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.158 SBFM

Signed bitfield move, with sign replication to left and zeros to right

This instruction is used by the aliases ASR (immediate), SBFIZ, SBFX, SXTB, SXTH, and SXTW. See the *Alias conditions* on page C6-652 table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0)

```
SBFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant (sf = 1, N = 1)

```
SBFM <Xd>, <Xn>, #<immr>, #<imms>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

boolean inzero;
boolean extend;
integer R;
integer S;
bits(datasize) wmask;
bits(datasize) tmask;

case opc of
    when '00' inzero = TRUE;  extend = TRUE;    // SBFM
    when '01' inzero = FALSE; extend = FALSE;   // BFM
    when '10' inzero = TRUE;  extend = FALSE;   // UBFM
    when '11' UnallocatedEncoding();

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
S = UInt(imms);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Alias conditions

Alias	of variant	is preferred when
ASR (immediate)	32-bit	`imms == '011111'`
ASR (immediate)	64-bit	`imms == '111111'`
SBFIZ	-	`UInt(imms) < UInt(immr)`
SBFX	-	`BFXPreferred(sf, opc<1>, imms, immr)`
SXTB	-	`immr == '000000' && imms == '000111'`
SXTH	-	`immr == '000000' && imms == '001111'`
SXTW	-	`immr == '000000' && imms == '011111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

`<immr>` For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the immr field.

`<immr>` For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the immr field.

`<imms>` For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the imms field.

`<imms>` For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the imms field.

Operation

```
bits(datasize) dst = if inzero then Zeros() else X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

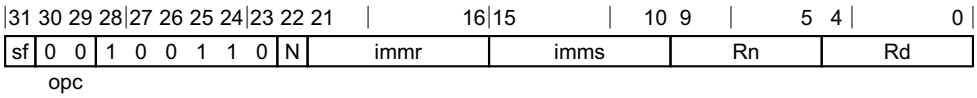
// determine extension bits (sign, zero or dest register)
bits(datasize) top = if extend then Replicate(src<S>) else dst;

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

C6.6.159 SBFX

Signed bitfield extract

This instruction is an alias of the SBFM instruction.



32-bit variant (sf = 0, N = 0)

`SBFX <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)`

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

64-bit variant (sf = 1, N = 1)

`SBFX <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`SBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)`

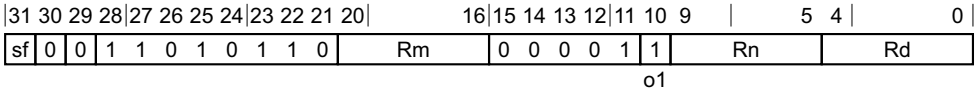
and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.160 SDIV

Signed divide: `Rd = Rn / Rm`



32-bit variant (sf = 0)

```
SDIV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
SDIV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean unsigned = (o1 == '0');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;

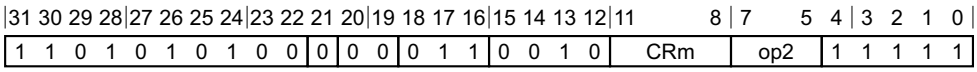
if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero (Int(operand1, unsigned) / Int(operand2, unsigned));

X[d] = result<datasize-1:0>;
```

C6.6.161 SEV

Send event

This instruction is an alias of the HINT instruction.



System variant

`SEV`

is equivalent to

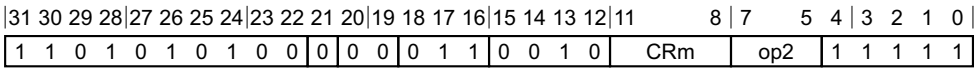
`HINT #4`

and is the preferred disassembly when `UInt(CRm:op2) == 4`.

C6.6.162 SEVL

Send event local.

This instruction is an alias of the HINT instruction.



System variant

`SEVL`

is equivalent to

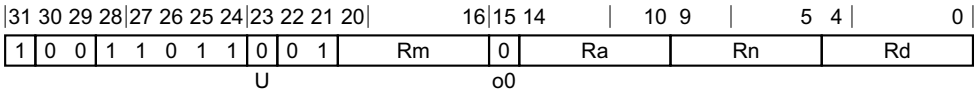
`HINT #5`

and is the preferred disassembly when `UInt(CRm:op2) == 5`.

C6.6.163 SMADDL

Signed multiply-add long: `Xd = Xa + Wn * Wm`

This instruction is used by the alias SMULL. See the *Alias conditions* table for details of when each alias is preferred.



64-bit variant

```
SMADDL <Xd>, <Wn>, <Wm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
SMULL	`Ra == '11111'`

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

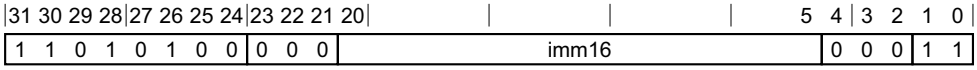
integer result;

if sub_op then
    result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
    result = Int(operand3, unsigned) + (Int(operand1, unsigned) * Int(operand2, unsigned));

X[d] = result<63:0>;
```

C6.6.164 SMC

Generate exception targeting exception level 3



System variant

```
SMC #<imm>

bits(16) imm = imm16;
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.

Operation

```
if !HaveEL(EL3) || PSTATE.EL == EL0 then
    UnallocatedEncoding();

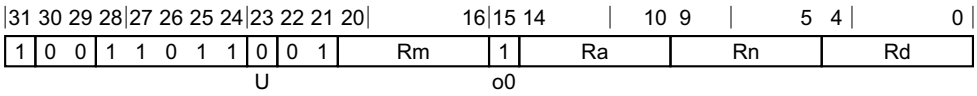
AArch64.CheckForSMCTrap();

if SCR_EL3.SMD == '1' then
    // SMC disabled
    if IsSecure() then
        // Executes either as a NOP or UNALLOCATED.
        c = ConstrainUnpredictable();
        assert c IN {Constraint_NOP, Constraint_UNDEF};
        if c == Constraint_NOP then EndOfInstruction();
    UnallocatedEncoding();
else
    AArch64.CallSecureMonitor(imm);
```

C6.6.165 SMNEGL

Signed multiply-negate long: `Xd = -(Wn * Wm)`

This instruction is an alias of the SMSUBL instruction.



64-bit variant

`SMNEGL <Xd>, <Wn>, <Wm>`

is equivalent to

`SMSUBL <Xd>, <Wn>, <Wm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

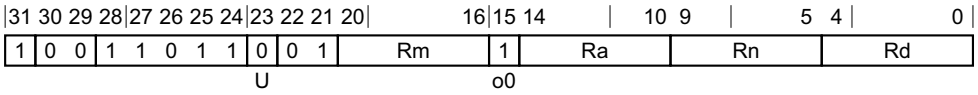
`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.166 SMSUBL

Signed multiply-subtract long: `Xd = Xa - Wn * Wm`

This instruction is used by the alias SMNEGL. See the *Alias conditions* table for details of when each alias is preferred.



64-bit variant

```
SMSUBL <Xd>, <Wn>, <Wm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
SMNEGL	`Ra == '11111'`

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Wn> Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

<Wm> Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

<Xa> Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

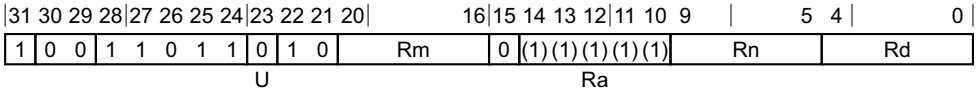
integer result;

if sub_op then
    result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
    result = Int(operand3, unsigned) + (Int(operand1, unsigned) * Int(operand2, unsigned));

X[d] = result<63:0>;
```

C6.6.167 SMULH

Signed multiply high: `Xd = bits<127:64> of Xn * Xm`



64-bit variant

```
SMULH <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);           // ignored by UMULH/SMULH
integer destsize = 64;
integer datasize = destsize;
boolean unsigned = (U == '1');
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

integer result;

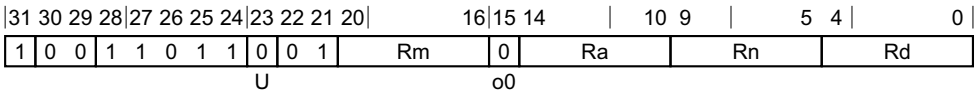
result = Int(operand1, unsigned) * Int(operand2, unsigned);

X[d] = result<127:64>;
```

C6.6.168 SMULL

Signed multiply long: `Xd = Wn * Wm`

This instruction is an alias of the SMADDL instruction.



64-bit variant

`SMULL <Xd>, <Wn>, <Wm>`

is equivalent to

`SMADDL <Xd>, <Wn>, <Wm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

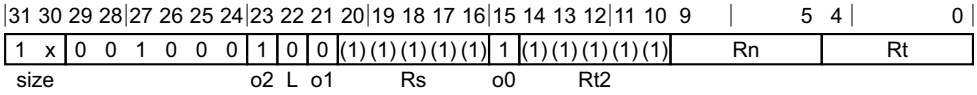
`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.169 STLR

Store-release register



32-bit variant (size = 10)

```
STLR <Wt>, [<Xn|SP>{,#0}]
```

64-bit variant (size = 11)

```
STLR <Xt>, [<Xn|SP>{,#0}]

integer n = UInt(Rn);
integer t = UInt(Rt);
integer t2 = UInt(Rt2); // ignored by load/store single register
integer s = UInt(Rs);   // ignored by all loads and store-release

if o2:o1:o0 == '100' || o2:o1:o0 == '11x' then UnallocatedEncoding();
if o1 == '1' && size<1> == '0' then UnallocatedEncoding();

AccType acctype = if o0 == '1' then AccType_ORDERED else AccType_ATOMIC;
boolean excl = (o2 == '0');
boolean pair = (o1 == '1');
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer elsize = 8 << UInt(size);
integer regsize = if elsize == 64 then 64 else 32;
integer datasize = if pair then elsize * 2 else elsize;
```

Assembler symbols

<Wt>	Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.
<Xt>	Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

Operation

```
bits(64) address;

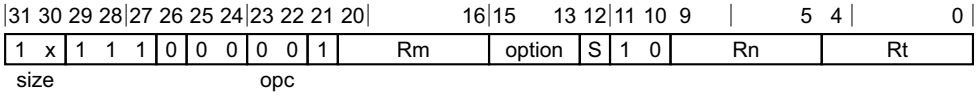
C6.6.179 STR (register)

Store register (register offset)



32-bit variant (size = 10)

```
STR <Wt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

64-bit variant (size = 11)

```
STR <Xt>, [<Xn|SP>, <R><m>{, <extend> {<amount>}}]
```

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(size);
if option<1> == '0' then UnallocatedEncoding(); // sub-word index
ExtendType extend_type = DecodeRegExtend(option);
integer shift = if S == '1' then scale else 0;
```

Assembler symbols

`<Wt>` Is the 32-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xt>` Is the 64-bit name of the general-purpose register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = `011`

RESERVED when option = `10x`

SXTW when option = `110`

SXTX when option = `111`

`<amount>` For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = `0`

#2 when S = `1`

`<amount>` For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = `0`

#3 when S = 1

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
AccType acctype = AccType_NORMAL;
MemOp memop;

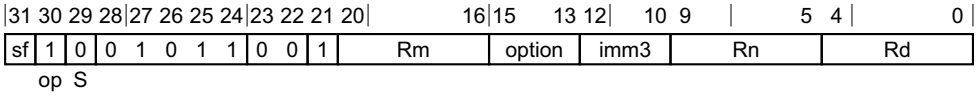
C6.6.194 SUB (extended register)

Subtract (extended register): `Rd = Rn - LSL(extend(Rm), amount)`



32-bit variant (sf = 0)

```
SUB <Wd|WSP>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant (sf = 1)

```
SUB <Xd|SP>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

W when option = `00x`

W when option = `010`

X when option = `x11`

W when option = `10x`

W when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

`<extend>` For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = `000`

UXTH when option = `001`

LSL|UXTW when option = `010`

UXTX when option = `011`

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rd or Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

<extend> For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rd or Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

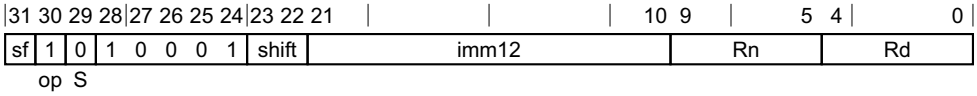
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.195 SUB (immediate)

Subtract (immediate): `Rd = Rn - shift(imm)`



32-bit variant (sf = 0)

```
SUB <Wd|WSP>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant (sf = 1)

```
SUB <Xd|SP>, <Xn|SP>, #<imm>{, <shift>}

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Assembler symbols

`<Wd|WSP>` Is the 32-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xd|SP>` Is the 64-bit name of the destination general-purpose register or stack pointer, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

LSL #12 when shift = `01`

RESERVED when shift = `1x`

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = imm;
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';
```

```
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

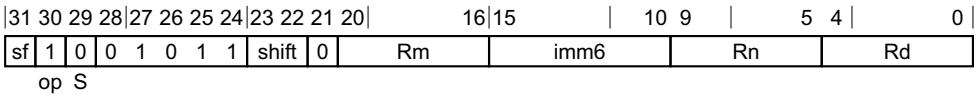
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.196 SUB (shifted register)

Subtract (shifted register): `Rd = Rn - shift(Rm, amount)`

This instruction is used by the alias NEG. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SUB <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
SUB <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
NEG	`Rn == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

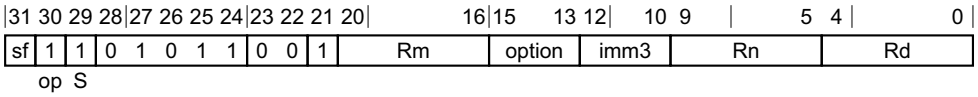
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.197 SUBS (extended register)

Subtract (extended register), setting the condition flags: `Rd = Rn - LSL(extend(Rm), amount)`

This instruction is used by the alias CMP (extended register). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SUBS <Wd>, <Wn|WSP>, <Wm>{, <extend> {#<amount>}}
```

64-bit variant (sf = 1)

```
SUBS <Xd>, <Xn|SP>, <R><m>{, <extend> {#<amount>}}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
ExtendType extend_type = DecodeRegExtend(option);
integer shift = UInt(imm3);
if shift > 4 then ReservedValue();
```

Alias conditions

Alias	is preferred when
CMP (extended register)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the first source general-purpose register or stack pointer, encoded in the Rn field.

`<R>` Is a width specifier, encoded in the option field:

- **W** when option = `00x`
- **W** when option = `010`
- **X** when option = `x11`
- **W** when option = `10x`
- **W** when option = `110`

`<m>` Is the number [0-30] of the second general-purpose source register or the name ZR (31), encoded in the Rm field.

<extend> For the 32-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

LSL|UXTW when option = 010

UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rn is '11111' (WSP) and option is '010' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTW must be used when option is '010'.

<extend> For the 64-bit variant: is the extension to be applied to the second source operand, encoded in the option field:

UXTB when option = 000

UXTH when option = 001

UXTW when option = 010

LSL|UXTX when option = 011

SXTB when option = 100

SXTH when option = 101

SXTW when option = 110

SXTX when option = 111

If Rn is '11111' (SP) and option is '011' then LSL is the preferred name, but may be omitted when the shift amount is zero. In all other cases <extend> is required, and UXTX must be used when option is '011'.

<amount> Is the left shift amount to be applied after extension in the range 0 to 4, defaulting to 0, encoded in the imm3 field. It must be omitted when <extend> is omitted, is required when <extend> is LSL, and is optional when <extend> is present but not LSL.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = ExtendReg(m, extend_type, shift);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

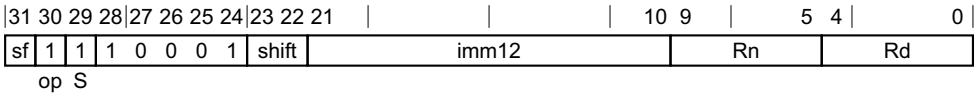
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.198 SUBS (immediate)

Subtract (immediate), setting the condition flags: `Rd = Rn - shift(imm)`

This instruction is used by the alias CMP (immediate). See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SUBS <Wd>, <Wn|WSP>, #<imm>{, <shift>}
```

64-bit variant (sf = 1)

```
SUBS <Xd>, <Xn|SP>, #<imm>{, <shift>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');
bits(datasize) imm;

case shift of
    when '00' imm = ZeroExtend(imm12, datasize);
    when '01' imm = ZeroExtend(imm12:Zeros(12), datasize);
    when '1x' ReservedValue();
```

Alias conditions

Alias	is preferred when
CMP (immediate)	`Rd == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn|WSP>` Is the 32-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn|SP>` Is the 64-bit name of the source general-purpose register or stack pointer, encoded in the Rn field.

`<imm>` Is an unsigned immediate, in the range 0 to 4095, encoded in the imm12 field.

`<shift>` Is the optional left shift to apply to the immediate, defaulting to LSL #0 and encoded in the shift field:

LSL #0 when shift = `00`

LSL #12 when shift = `01`

RESERVED when shift = `1x`

Operation

```
bits(datasize) result;
bits(datasize) operand1 = if n == 31 then SP[] else X[n];
bits(datasize) operand2 = imm;
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

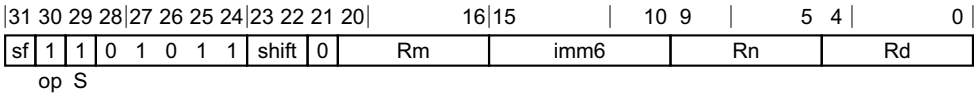
if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

if d == 31 && !setflags then
    SP[] = result;
else
    X[d] = result;
```

C6.6.199 SUBS (shifted register)

Subtract (shifted register), setting the condition flags: `Rd = Rn - shift(Rm, amount)`

This instruction is used by the aliases CMP (shifted register) and NEGS. See the *Alias conditions* table for details of when each alias is preferred.



32-bit variant (sf = 0)

```
SUBS <Wd>, <Wn>, <Wm>{, <shift> #<amount>}
```

64-bit variant (sf = 1)

```
SUBS <Xd>, <Xn>, <Xm>{, <shift> #<amount>}
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean sub_op = (op == '1');
boolean setflags = (S == '1');

if shift == '11' then ReservedValue();
if sf == '0' && imm6<5> == '1' then ReservedValue();

ShiftType shift_type = DecodeShift(shift);
integer shift_amount = UInt(imm6);
```

Alias conditions

Alias	is preferred when
CMP (shifted register)	`Rd == '11111'`
NEGS	`Rn == '11111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift type to be applied to the second source operand, defaulting to LSL and encoded in the shift field:

LSL when shift = `00`

LSR when shift = `01`

ASR when shift = `10`

RESERVED when shift = 11

<amount> For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

<amount> For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field.

Operation

```
bits(datasize) result;
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = ShiftReg(m, shift_type, shift_amount);
bits(4) nzcv;
bit carry_in;

if sub_op then
    operand2 = NOT(operand2);
    carry_in = '1';
else
    carry_in = '0';

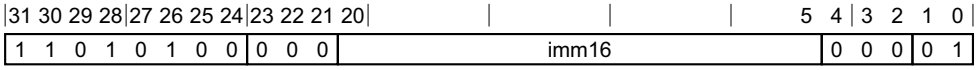
(result, nzcv) = AddWithCarry(operand1, operand2, carry_in);

if setflags then
    PSTATE.<N,Z,C,V> = nzcv;

X[d] = result;
```

C6.6.200 SVC

Generate exception targeting exception level 1



System variant

```
SVC #<imm>

bits(16) imm = imm16;
```

Assembler symbols

<imm> Is a 16-bit unsigned immediate, in the range 0 to 65535, encoded in the imm16 field.

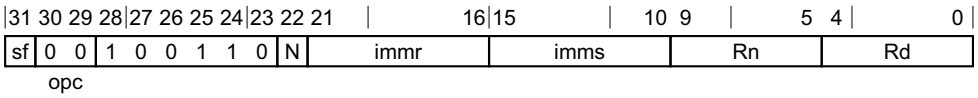
Operation

```
AArch64.CallSupervisor(imm);
```

C6.6.201 SXTB

Signed extend byte: `Rd = SignExtend(Wn<7:0>)`

This instruction is an alias of the SBFM instruction.



32-bit variant (sf = 0, N = 0)

`SXTB <Wd>, <Wn>`

is equivalent to

`SBFM <Wd>, <Wn>, #0, #7`

and is the preferred disassembly when `immr == '000000' && imms == '000111'`.

64-bit variant (sf = 1, N = 1)

`SXTB <Xd>, <Wn>`

is equivalent to

`SBFM <Xd>, <Xn>, #0, #7`

and is the preferred disassembly when `immr == '000000' && imms == '000111'`.

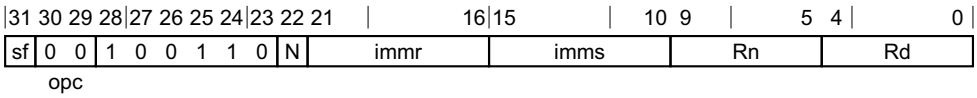
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

C6.6.202 SXTH

Signed extend halfword: `Rd = SignExtend(Wn<15:0>)`

This instruction is an alias of the SBFM instruction.



32-bit variant (sf = 0, N = 0)

`SXTH <Wd>, <Wn>`

is equivalent to

`SBFM <Wd>, <Wn>, #0, #15`

and is the preferred disassembly when `immr == '000000' && imms == '001111'`.

64-bit variant (sf = 1, N = 1)

`SXTH <Xd>, <Wn>`

is equivalent to

`SBFM <Xd>, <Xn>, #0, #15`

and is the preferred disassembly when `immr == '000000' && imms == '001111'`.

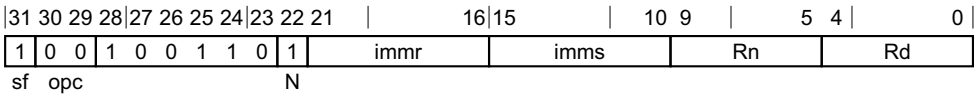
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

C6.6.203 SXTW

Signed extend word: `Xd = SignExtend(Wn<31:0>)`

This instruction is an alias of the SBFM instruction.



64-bit variant

`SXTW <Xd>, <Wn>`

is equivalent to

`SBFM <Xd>, <Xn>, #0, #31`

and is the preferred disassembly when `immr == '000000' && imms == '011111'`.

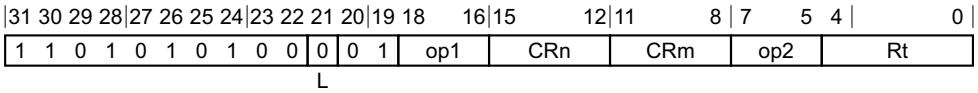
Assembler symbols

`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

C6.6.204 SYS

System instruction

This instruction is used by the aliases AT, DC, IC, and TLBI. See the *Alias conditions* table for details of when each alias is preferred.



System variant

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}

CheckSystemAccess(op1);

integer t = UInt(Rt);

integer sys_op0 = 1;
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
boolean has_result = (L == '1');
```

Alias conditions

Alias	is preferred when
AT	`SysOp(op1,CRn,CRm,op2) == Sys_AT`
DC	`SysOp(op1,CRn,CRm,op2) == Sys_DC`
IC	`SysOp(op1,CRn,CRm,op2) == Sys_IC`
TLBI	`SysOp(op1,CRn,CRm,op2) == Sys_TLBI`

Assembler symbols

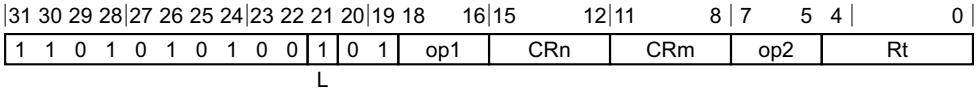
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.
<Xt>	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the Rt field.

Operation

```
if has_result then
    X[t] = SysOp_R(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
else
    SysOp_W(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

C6.6.205 SYSL

System instruction with result



System variant

```
SYSL <Xt>, #<op1>, <Cn>, <Cm>, #<op2>

CheckSystemAccess(op1);

integer t = UInt(Rt);

integer sys_op0 = 1;
integer sys_op1 = UInt(op1);
integer sys_op2 = UInt(op2);
integer sys_crn = UInt(CRn);
integer sys_crm = UInt(CRm);
boolean has_result = (L == '1');
```

Assembler symbols

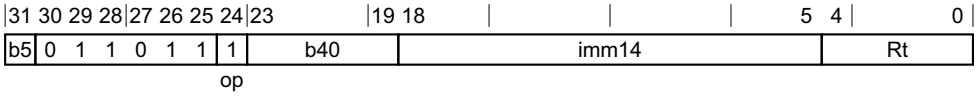
<Xt>	Is the 64-bit name of the general-purpose destination register, encoded in the Rt field.
<op1>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
<Cn>	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
<Cm>	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
<op2>	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.

Operation

```
if has_result then
    X[t] = SysOp_R(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2);
else
    SysOp_W(sys_op0, sys_op1, sys_crn, sys_crm, sys_op2, X[t]);
```

C6.6.206 TBNZ

Test bit and branch if nonzero to a label at a PC-relative offset, without affecting the condition flags, and with a hint that this is not a subroutine call or return



14-bit signed PC-relative branch offset variant

```
TBNZ <R><t>, #<imm>, <label>

integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bit bit_val = op;
bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler symbols

<R> Is a width specifier, encoded in the b5 field:

W when b5 = 0

X when b5 = 1

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the Rt field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in b5:b40.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as imm14 times 4.

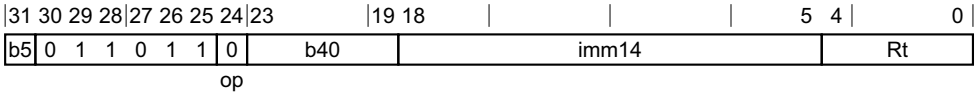
Operation

```
bits(datasize) operand = X[t];

if operand<bit_pos> == bit_val then
    BranchTo(PC[] + offset, BranchType_JMP);
```

C6.6.207 TBZ

Test bit and branch if zero to a label at a PC-relative offset, without affecting the condition flags, and with a hint that this is not a subroutine call or return



14-bit signed PC-relative branch offset variant

```
TBZ <R><t>, #<imm>, <label>

integer t = UInt(Rt);

integer datasize = if b5 == '1' then 64 else 32;
integer bit_pos = UInt(b5:b40);
bit bit_val = op;
bits(64) offset = SignExtend(imm14:'00', 64);
```

Assembler symbols

<R> Is a width specifier, encoded in the b5 field:

W when b5 = 0

X when b5 = 1

In assembler source code an 'X' specifier is always permitted, but a 'W' specifier is only permitted when the bit number is less than 32.

<t> Is the number [0-30] of the general-purpose register to be tested or the name ZR (31), encoded in the Rt field.

<imm> Is the bit number to be tested, in the range 0 to 63, encoded in b5:b40.

<label> Is the program label to be conditionally branched to. Its offset from the address of this instruction, in the range +/-32KB, is encoded as imm14 times 4.

Operation

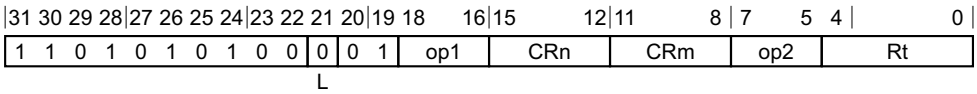
```
bits(datasize) operand = X[t];

if operand<bit_pos> == bit_val then
    BranchTo(PC[] + offset, BranchType_JMP);
```

C6.6.208 TLBI

TLB invalidate operation

This instruction is an alias of the SYS instruction.



System variant

```
TLBI <tlbi_op>{, <Xt>}
```

is equivalent to

```
SYS #<op1>, <Cn>, <Cm>, #<op2>{, <Xt>}
```

and is the preferred disassembly when `SysOp(op1,CRn,CRm,op2) == Sys_TLBI`.

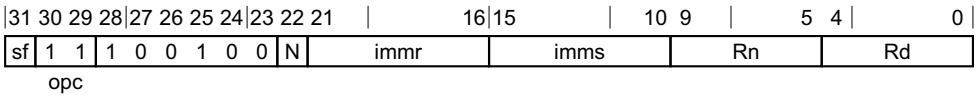
Assembler symbols

`<op1>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op1 field.
`<Cn>`	Is a name 'Cn', with 'n' in the range 0 to 15, encoded in the CRn field.
`<Cm>`	Is a name 'Cm', with 'm' in the range 0 to 15, encoded in the CRm field.
`<op2>`	Is a 3-bit unsigned immediate, in the range 0 to 7, encoded in the op2 field.
`<tlbi_op>`	Is a TLBI operation name, as listed for the TLBI system operation group, encoded in the op1:CRn:CRm:op2.
`<Xt>`	Is the 64-bit name of the optional general-purpose source register, defaulting to '11111', encoded in the Rt field.

C6.6.209 TST (immediate)

Test bits (immediate), setting the condition flags and discarding the result: `Rn AND imm`

This instruction is an alias of the ANDS (immediate) instruction.



32-bit variant (sf = 0, N = 0)

`TST <Wn>, #<imm>`

is equivalent to

`ANDS WZR, <Wn>, #<imm>`

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

`TST <Xn>, #<imm>`

is equivalent to

`ANDS XZR, <Xn>, #<imm>`

and is the preferred disassembly when `Rd == '11111'`.

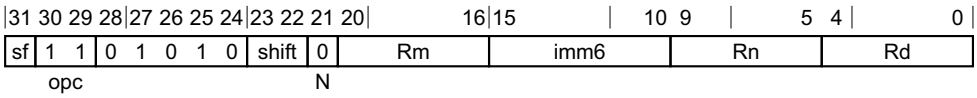
Assembler symbols

`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<imm>`	Is the bitmask immediate, encoded in N:imms:immr.

C6.6.210 TST (shifted register)

Test bits (shifted register), setting the condition flags and discarding the result: `Rn AND shift(Rm, amount)`

This instruction is an alias of the ANDS (shifted register) instruction.



32-bit variant (sf = 0)

`TST <Wn>, <Wm>{, <shift> #<amount>}`

is equivalent to

`ANDS WZR, <Wn>, <Wm>{, <shift> #<amount>}`

and is the preferred disassembly when `Rd == '11111'`.

64-bit variant (sf = 1)

`TST <Xn>, <Xm>{, <shift> #<amount>}`

is equivalent to

`ANDS XZR, <Xn>, <Xm>{, <shift> #<amount>}`

and is the preferred disassembly when `Rd == '11111'`.

Assembler symbols

`<Wn>` Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.

`<Xn>` Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.

`<Xm>` Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

`<shift>` Is the optional shift to be applied to the final source, defaulting to LSL and encoded in the shift field:

- **LSL** when shift = `00`
- **LSR** when shift = `01`
- **ASR** when shift = `10`
- **ROR** when shift = `11`

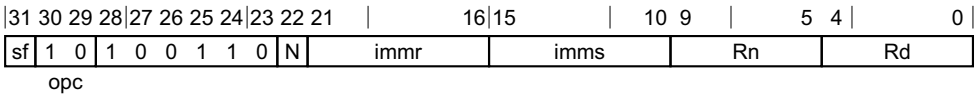
`<amount>` For the 32-bit variant: is the shift amount, in the range 0 to 31, defaulting to 0 and encoded in the imm6 field.

`<amount>` For the 64-bit variant: is the shift amount, in the range 0 to 63, defaulting to 0 and encoded in the imm6 field,

C6.6.211 UBFIZ

Unsigned bitfield insert in zero, with zeros to left and right

This instruction is an alias of the UBFM instruction.



32-bit variant (sf = 0, N = 0)

`UBFIZ <Wd>, <Wn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Wd>, <Wn>, #(-<lsb> MOD 32), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

64-bit variant (sf = 1, N = 1)

`UBFIZ <Xd>, <Xn>, #<lsb>, #<width>`

is equivalent to

`UBFM <Xd>, <Xn>, #(-<lsb> MOD 64), #(<width>-1)`

and is the preferred disassembly when `UInt(imms) < UInt(immr)`.

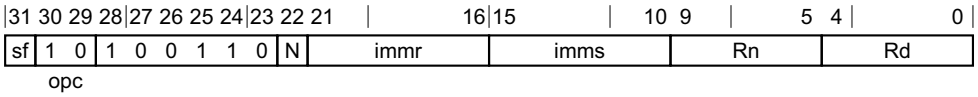
Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.212 UBFM

Unsigned bitfield move, with zeros to left and right

This instruction is used by the aliases LSL (immediate), LSR (immediate), UBFIZ, UBFX, UXTB, and UXTH. See the *Alias conditions* on page C6-756 table for details of when each alias is preferred.



32-bit variant (sf = 0, N = 0)

```
UBFM <Wd>, <Wn>, #<immr>, #<imms>
```

64-bit variant (sf = 1, N = 1)

```
UBFM <Xd>, <Xn>, #<immr>, #<imms>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer datasize = if sf == '1' then 64 else 32;

boolean inzero;
boolean extend;
integer R;
integer S;
bits(datasize) wmask;
bits(datasize) tmask;

case opc of
    when '00' inzero = TRUE;  extend = TRUE;    // SBFM
    when '01' inzero = FALSE; extend = FALSE;   // BFM
    when '10' inzero = TRUE;  extend = FALSE;   // UBFM
    when '11' UnallocatedEncoding();

if sf == '1' && N != '1' then ReservedValue();
if sf == '0' && (N != '0' || immr<5> != '0' || imms<5> != '0') then ReservedValue();

R = UInt(immr);
S = UInt(imms);
(wmask, tmask) = DecodeBitMasks(N, imms, immr, FALSE);
```

Alias conditions

Alias	of variant	is preferred when
LSL (immediate)	32-bit	`imms != '011111' && imms + 1 == immr`
LSL (immediate)	64-bit	`imms != '111111' && imms + 1 == immr`
LSR (immediate)	32-bit	`imms == '011111'`
LSR (immediate)	64-bit	`imms == '111111'`
UBFIZ	-	`UInt(imms) < UInt(immr)`
UBFX	-	`BFXPreferred(sf, opc<1>, imms, immr)`
UXTB	-	`immr == '000000' && imms == '000111'`
UXTH	-	`immr == '000000' && imms == '001111'`

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xn>` Is the 64-bit name of the general-purpose source register, encoded in the Rn field.

`<immr>` For the 32-bit variant: is the right rotate amount, in the range 0 to 31, encoded in the immr field.

`<immr>` For the 64-bit variant: is the right rotate amount, in the range 0 to 63, encoded in the immr field.

`<imms>` For the 32-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 31, encoded in the imms field.

`<imms>` For the 64-bit variant: is the leftmost bit number to be moved from the source, in the range 0 to 63, encoded in the imms field.

Operation

```
bits(datasize) dst = if inzero then Zeros() else X[d];
bits(datasize) src = X[n];

// perform bitfield move on low bits
bits(datasize) bot = (dst AND NOT(wmask)) OR (ROR(src, R) AND wmask);

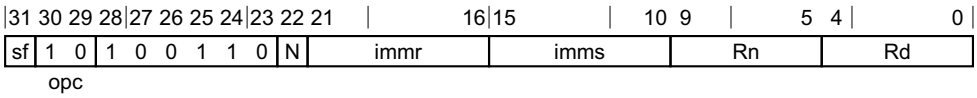
// determine extension bits (sign, zero or dest register)
bits(datasize) top = if extend then Replicate(src<S>) else dst;

// combine extension bits and result bits
X[d] = (top AND NOT(tmask)) OR (bot AND tmask);
```

C6.6.213 UBFX

Unsigned bitfield extract

This instruction is an alias of the UBFM instruction.



32-bit variant (sf = 0, N = 0)

```
UBFX <Wd>, <Wn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Wd>, <Wn>, #<lsb>, #(<lsb>+<width>-1)
```

and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

64-bit variant (sf = 1, N = 1)

```
UBFX <Xd>, <Xn>, #<lsb>, #<width>
```

is equivalent to

```
UBFM <Xd>, <Xn>, #<lsb>, #(<lsb>+<width>-1)
```

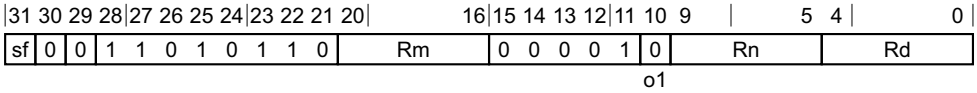
and is the preferred disassembly when `BFXPreferred(sf, opc<1>, imms, immr)`.

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the general-purpose source register, encoded in the Rn field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the general-purpose source register, encoded in the Rn field.
`<lsb>`	For the 32-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 31.
`<lsb>`	For the 64-bit variant: is the bit number of the lsb of the source bitfield, in the range 0 to 63.
`<width>`	For the 32-bit variant: is the width of the bitfield, in the range 1 to 32-<lsb>.
`<width>`	For the 64-bit variant: is the width of the bitfield, in the range 1 to 64-<lsb>.

C6.6.214 UDIV

Unsigned divide: `Rd = Rn / Rm`



32-bit variant (sf = 0)

```
UDIV <Wd>, <Wn>, <Wm>
```

64-bit variant (sf = 1)

```
UDIV <Xd>, <Xn>, <Xm>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer datasize = if sf == '1' then 64 else 32;
boolean unsigned = (o1 == '0');
```

Assembler symbols

`<Wd>`	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
`<Wn>`	Is the 32-bit name of the first general-purpose source register, encoded in the Rn field.
`<Wm>`	Is the 32-bit name of the second general-purpose source register, encoded in the Rm field.
`<Xd>`	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
`<Xn>`	Is the 64-bit name of the first general-purpose source register, encoded in the Rn field.
`<Xm>`	Is the 64-bit name of the second general-purpose source register, encoded in the Rm field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
integer result;

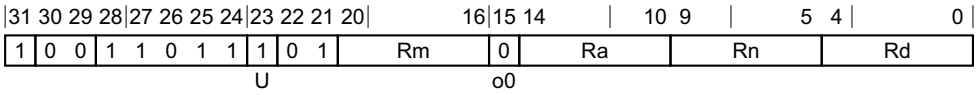
if IsZero(operand2) then
    result = 0;
else
    result = RoundTowardsZero (Int(operand1, unsigned) / Int(operand2, unsigned));

X[d] = result<datasize-1:0>;
```

C6.6.215 UMADDL

Unsigned multiply-add long: `Xd = Xa + Wn * Wm`

This instruction is used by the alias UMULL. See the *Alias conditions* table for details of when each alias is preferred.



64-bit variant

```
UMADDL <Xd>, <Wn>, <Wm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
UMULL	`Ra == '11111'`

Assembler symbols

<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Wn>	Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.
<Wm>	Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.
<Xa>	Is the 64-bit name of the third general-purpose source register holding the addend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

integer result;

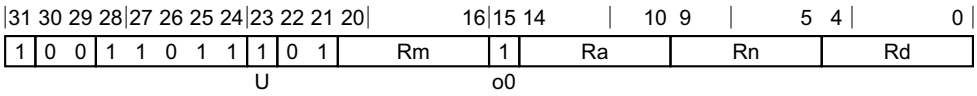
if sub_op then
    result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
    result = Int(operand3, unsigned) + (Int(operand1, unsigned) * Int(operand2, unsigned));

X[d] = result<63:0>;
```

C6.6.216 UMNEGL

Unsigned multiply-negate long: `Xd = -(Wn * Wm)`

This instruction is an alias of the UMSUBL instruction.



64-bit variant

`UMNEGL <Xd>, <Wn>, <Wm>`

is equivalent to

`UMSUBL <Xd>, <Wn>, <Wm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

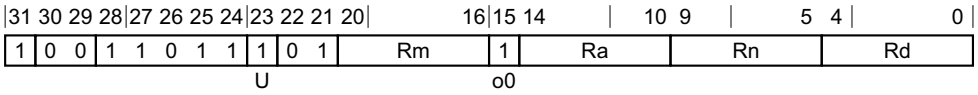
`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.217 UMSUBL

Unsigned multiply-subtract long: `Xd = Xa - Wn * Wm`

This instruction is used by the alias UMNEGL. See the *Alias conditions* table for details of when each alias is preferred.



64-bit variant

```
UMSUBL <Xd>, <Wn>, <Wm>, <Xa>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);
integer destsize = 64;
integer datasize = 32;
boolean sub_op = (o0 == '1');
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
UMNEGL	`Ra == '11111'`

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

`<Xa>` Is the 64-bit name of the third general-purpose source register holding the minuend, encoded in the Ra field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];
bits(destsize) operand3 = X[a];

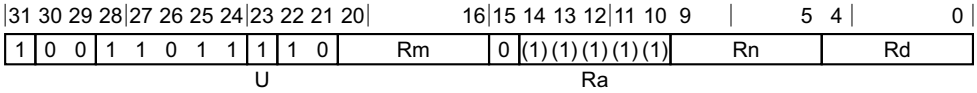
integer result;

if sub_op then
    result = Int(operand3, unsigned) - (Int(operand1, unsigned) * Int(operand2, unsigned));
else
    result = Int(operand3, unsigned) + (Int(operand1, unsigned) * Int(operand2, unsigned));

X[d] = result<63:0>;
```

C6.6.218 UMULH

Unsigned multiply high: `Xd = bits<127:64> of Xn * Xm`



64-bit variant

```
UMULH <Xd>, <Xn>, <Xm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer a = UInt(Ra);           // ignored by UMULH/SMULH
integer destsize = 64;
integer datasize = destsize;
boolean unsigned = (U == '1');
```

Assembler symbols

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Xn> Is the 64-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

<Xm> Is the 64-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

Operation

```
bits(datasize) operand1 = X[n];
bits(datasize) operand2 = X[m];

integer result;

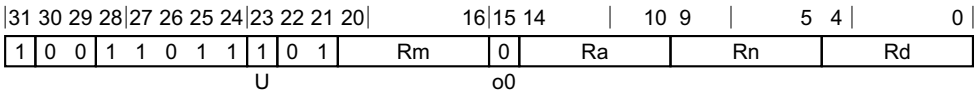
result = Int(operand1, unsigned) * Int(operand2, unsigned);

X[d] = result<127:64>;
```

C6.6.219 UMULL

Unsigned multiply long: `Xd = Wn * Wm`

This instruction is an alias of the UMADDL instruction.



64-bit variant

`UMULL <Xd>, <Wn>, <Wm>`

is equivalent to

`UMADDL <Xd>, <Wn>, <Wm>, XZR`

and is the preferred disassembly when `Ra == '11111'`.

Assembler symbols

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

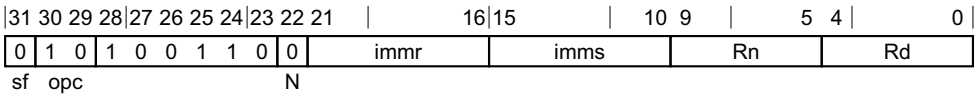
`<Wn>` Is the 32-bit name of the first general-purpose source register holding the multiplicand, encoded in the Rn field.

`<Wm>` Is the 32-bit name of the second general-purpose source register holding the multiplier, encoded in the Rm field.

C6.6.220 UXTB

Unsigned extend byte: `Wd = ZeroExtend(Wn<7:0>)`

This instruction is an alias of the UBFM instruction.



32-bit variant

`UXTB <Wd>, <Wn>`

is equivalent to

`UBFM <Wd>, <Wn>, #0, #7`

and is the preferred disassembly when `immr == '000000' && imms == '000111'`.

Assembler symbols

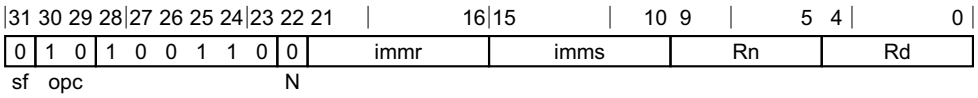
`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

C6.6.221 UXTH

Unsigned extend halfword: `Wd = ZeroExtend(Wn<15:0>)`

This instruction is an alias of the UBFM instruction.



32-bit variant

`UXTH <Wd>, <Wn>`

is equivalent to

`UBFM <Wd>, <Wn>, #0, #15`

and is the preferred disassembly when `immr == '000000' && imms == '001111'`.

Assembler symbols

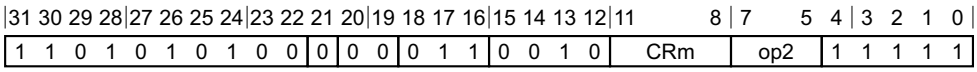
`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Wn>` Is the 32-bit name of the general-purpose source register, encoded in the Rn field.

C6.6.222 WFE

Wait for event

This instruction is an alias of the HINT instruction.



System variant

`WFE`

is equivalent to

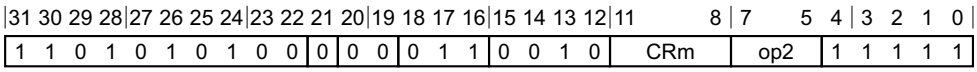
`HINT #2`

and is the preferred disassembly when `UInt(CRm:op2) == 2`.

C6.6.223 WFI

Wait for interrupt

This instruction is an alias of the HINT instruction.



System variant

`WFI`

is equivalent to

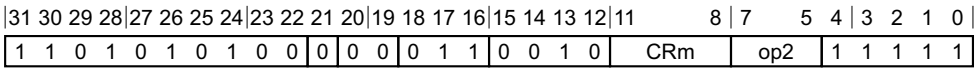
`HINT #3`

and is the preferred disassembly when `UInt(CRm:op2) == 3`.

C6.6.224 YIELD

Yield hint

This instruction is an alias of the HINT instruction.



System variant

`YIELD`

is equivalent to

`HINT #1`

and is the preferred disassembly when `UInt(CRm:op2) == 1`.

Chapter C7
A64 Advanced SIMD and Floating-point Instruction Descriptions

This chapter describes the A64 SIMD and floating-point instructions.

It contains the following sections:

C7.1 About the A64 Advanced SIMD and floating-point instruction descriptions

Alphabetical list of floating-point and Advanced SIMD instructions on page C7-773 is an alphabetical list of instructions that are part of the following two functional groups:

- Loads and store instructions associated with the SIMD and floating-point registers.
- Data processing instructions with SIMD and floating-point registers.

A64 instruction index by encoding on page C4-174 in the A64 Instruction Encodings chapter provides an overview of the instruction encodings as part of an instruction class within a functional group.

C7.2 About the SIMD and floating-point instructions

This section provides a general description of the SIMD and floating-point instructions. It contains the following subsections:

- *Register size*.
- *Data types*.
- *Condition flags and related instructions* on page C7-772.
- *General capabilities* on page C7-772.

C7.2.1 Register size

A64 provides a comprehensive set of packed Single Instruction Multiple Data (SIMD) and scalar operations using data held in the 32 entry 128-bit wide SIMD and floating-point register file.

Each SIMD and floating-point register can be used to hold:

- A single scalar value of the floating-point or integer type.
- A 64-bit wide vector containing one or more elements.
- A 128-bit wide vector containing two or more elements.

Where the entire 128-bit wide register is not fully utilized, the vector or scalar quantity is held in the least significant bits of the register, with the most significant bits being cleared to zero on a write, see *Vector formats* on page A1-37.

The following instructions can insert data into individual elements within a SIMD and floating-pointer register without clearing the remaining bits to zero:

- Insert vector element from another vector element or general-purpose register, `INS`.
- Load structure into a single lane, for example `LD3`.
- All second-part narrowing operations, for example `SHRN2`.

C7.2.2 Data types

The A64 instruction set provides support for arithmetic, conversion, and bitwise operations on:

- Half-precision, single-precision, and double-precision floating points.
- Signed and unsigned integers.
- Polynomials over {0, 1}.

For all AArch64 floating-point operations, including SIMD operations, the rounding mode and exception trap handling are controlled by the FPCR.

Note

AArch32 Advanced SIMD operations always use ARM standard floating-point arithmetic independent of the FPCR and FPSCR rounding mode. In addition, floating-point multiply-addition operations in AArch64 are always performed as fused operations, whereas AArch32 provides both fused and chained variants.

In addition to operations that consume and produce values of the same width and type, the A64 instruction set supports SIMD and scalar operations that produce a wider or narrower vector result:

- Where a SIMD operation narrows a 128-bit vector to a 64-bit vector, the A64 instruction set provides a second-part operation, for example `SHRN2`, that can pack the result of a second operation into the upper part of the same destination register.
- Where a SIMD operation widens a 64-bit vector to a 128-bit vector, the A64 instruction set provides a second-part operation, for example `SMLAL2`, that can extract the source from the upper 64 bits of the source registers.

All SIMD operations that could produce side-effects that are not limited to the destination SIMD and floating-point register, for example a potential update of FPSR.Q or FPSR.IDC, have a dedicated scalar variant to support the use of SIMD with loops requiring specialised head or tail handling, or both.

C7.2.3 Condition flags and related instructions

The A64 instruction set provides support for flag setting and conditional operations on the SIMD and floating-point register file:

- Floating-point `FCSEL` and `FCCMP` instructions are equivalent to the integer `CSEL` and `CCMP` instructions.
- Floating-point `FCMP`. `FCMPE`, `FCCMP`, and `FCCMP` set the PSTATE.{N, Z, C, V} flags based on the result of the floating-point comparison.
- Floating-point and integer instructions provide a means of producing either a scalar or a vector mask based on a comparison in a SIMD and floating-point register, for example `FCMEQ`.

Note

`FCMP` and `FCMPE` differ from the A32/T32 `VCMP` and `VCMPE` instructions, which use the dedicated FPSCR.NZCV field for the result. A64 instructions store the result of an `FCMP` or `FCMPE` operation in the PSTATE.{N, Z, C, V} field.

C7.2.4 General capabilities

A64 SIMD and floating-point instructions provide the following capabilities:

- General arithmetic on vector and scalar floating-point and integer values.
- Dedicated polynomial multiply over {0, 1}.
- Vector and scalar fused multiply-addition of single-precision and double-precision floating-points.
- Load and store of single and pairs of SIMD and floating-point registers.
- Load and store of structures and individual lanes of between one and four SIMD and floating-point registers.
- Direct conversion between 64-bit integers and floating-point values, with explicit rounding.
- Double-rounding free conversion between double-precision and half-precision floating-point values.
- Comprehensive SIMD with widening and narrowing support.
- Vector to scalar reduction returning the minimum or maximum value, or the sum.
- Floating-point to nearest integer in floating-point format.

C7.3 Alphabetical list of floating-point and Advanced SIMD instructions

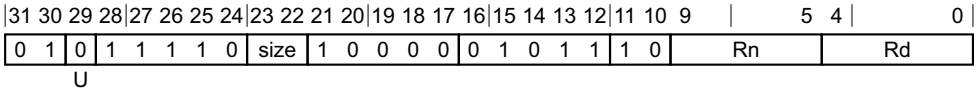
This section lists every section in the floating-point and Advanced SIMD categories of the A64 instruction set. For details of the format used, see *Structure of the A64 assembler language* on page C1-111.

C7.3.1 ABS

Absolute value (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

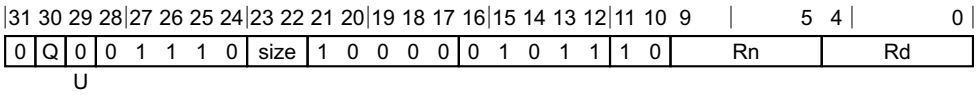
```
ABS <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean neg = (U == '1');
```

Vector



Vector variant

```
ABS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean neg = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

RESERVED when size = 0x

RESERVED when size = 10

D when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

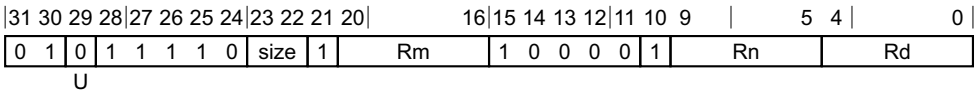
V[d] = result;
```

C7.3.2 ADD (vector)

Add (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar

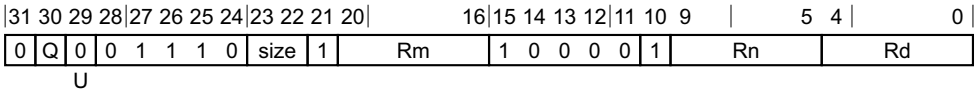


Scalar variant

```
ADD <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

Vector



Vector variant

```
ADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

RESERVED when size = 0x

RESERVED when size = 10

D when size = 11

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<m> Is the number of the second SIMD&FP source register, encoded in the Rm field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation for all classes

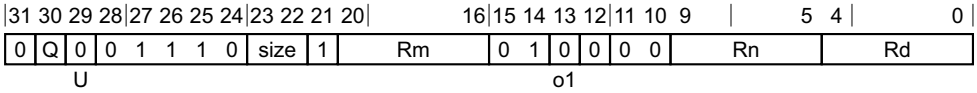
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;
```

C7.3.3 ADDHN, ADDHN2

Add returning high narrow



Three registers, not all the same type variant

```
ADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

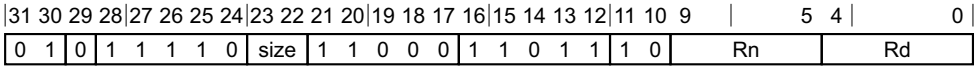
```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize)   result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

C7.3.4 ADDP (scalar)

Add pair of elements (scalar)



Advanced SIMD variant

```
ADDP <V><d>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();

integer esize = 8 << UInt(size);
integer datasize = esize * 2;
integer elements = 2;

ReduceOp op = ReduceOp_ADD;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the size field:

RESERVED when size = 0x

RESERVED when size = 10

D when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<T> Is the source arrangement specifier, encoded in the size field:

RESERVED when size = 0x

RESERVED when size = 10

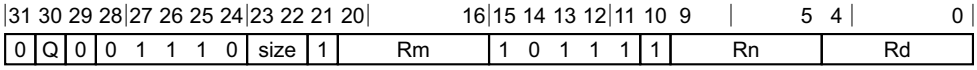
2D when size = 11

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(op, operand, esize);
```

C7.3.5 ADDP (vector)

Add pairwise (vector)



Three registers of the same type variant

```
ADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

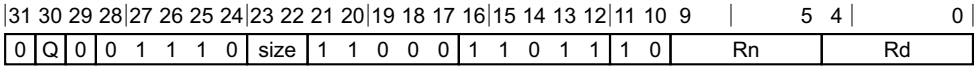
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[concat, 2*e, esize];
    element2 = Elem[concat, (2*e)+1, esize];
    Elem[result, e, esize] = element1 + element2;

V[d] = result;
```

C7.3.6 ADDV

Add across vector



Advanced SIMD variant

```
ADDV <V><d>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '100' then ReservedValue();
if size == '11' then ReservedValue();

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

ReduceOp op = ReduceOp_ADD;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the size field:

B when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

RESERVED when size = 10, Q = 0

4S when size = 10, Q = 1

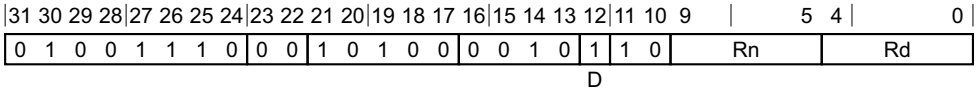
RESERVED when size = 11, Q = x

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(op, operand, esize);
```

C7.3.7 AESD

AES single round decryption



Advanced SIMD variant

```
AESD <Vd>.16B, <Vn>.16B

integer d = UInt(Rd);
integer n = UInt(Rn);
if ! HaveCryptoExt() then UnallocatedEncoding();
boolean decrypt = (D == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the Rd field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the Rn field.

Operation

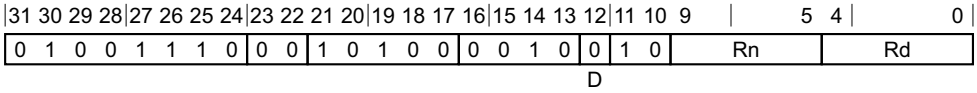
```
CheckCryptoEnabled64();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
if decrypt then
    result = AESInvSubBytes(AESInvShiftRows(result));
else
    result = AESSubBytes(AESShiftRows(result));

V[d] = result;
```

C7.3.8 AESE

AES single round encryption



Advanced SIMD variant

```
AESE <Vd>.16B, <Vn>.16B

integer d = UInt(Rd);
integer n = UInt(Rn);
if ! HaveCryptoExt() then UnallocatedEncoding();
boolean decrypt = (D == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP source and destination register, encoded in the Rd field.

<Vn> Is the name of the second SIMD&FP source register, encoded in the Rn field.

Operation

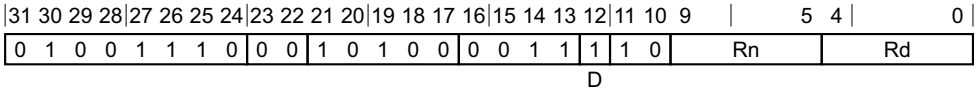
```
CheckCryptoEnabled64();

bits(128) operand1 = V[d];
bits(128) operand2 = V[n];
bits(128) result;
result = operand1 EOR operand2;
if decrypt then
    result = AESInvSubBytes(AESInvShiftRows(result));
else
    result = AESSubBytes(AESShiftRows(result));

V[d] = result;
```

C7.3.9 AESIMC

AES inverse mix columns



Advanced SIMD variant

```
AESIMC <Vd>.16B, <Vn>.16B

integer d = UInt(Rd);
integer n = UInt(Rn);
if ! HaveCryptoExt() then UnallocatedEncoding();
boolean decrypt = (D == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

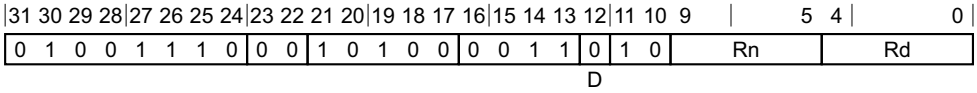
Operation

```
CheckCryptoEnabled64();

bits(128) operand = V[n];
bits(128) result;
if decrypt then
    result = AESInvMixColumns(operand);
else
    result = AESMixColumns(operand);
V[d] = result;
```

C7.3.10 AESMC

AES mix columns



Advanced SIMD variant

```
AESMC <Vd>.16B, <Vn>.16B

integer d = UInt(Rd);
integer n = UInt(Rn);
if ! HaveCryptoExt() then UnallocatedEncoding();
boolean decrypt = (D == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

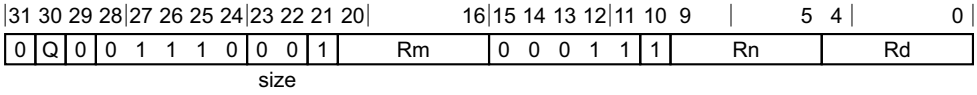
Operation

```
CheckCryptoEnabled64();

bits(128) operand = V[n];
bits(128) result;
if decrypt then
    result = AESInvMixColumns(operand);
else
    result = AESMixColumns(operand);
V[d] = result;
```

C7.3.11 AND (vector)

Bitwise AND (vector)



Three registers of the same type variant

```
AND <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean invert = (size<0> == '1');
LogicalOp op = if size<1> == '1' then LogicalOp_ORR else LogicalOp_AND;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND
        result = operand1 AND operand2;
    when LogicalOp_ORR
        result = operand1 OR operand2;

V[d] = result;
```

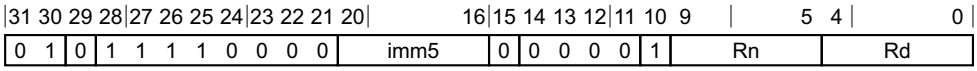
C7.3.31 DUP (element)

Duplicate vector element to vector or scalar

This instruction is used by the alias MOV (scalar). The alias is always the preferred disassembly.

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
DUP <V><d>, <Vn>.<T>[<index>]

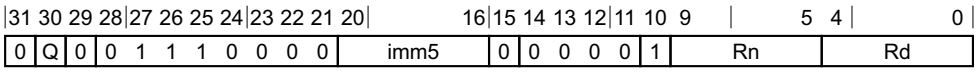
integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

integer esize = 8 << size;
integer datasize = esize;
integer elements = 1;
```

Vector



Vector variant

```
DUP <Vd>.<T>, <Vn>.<Ts>[<index>]

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer index = UInt(imm5<4:size+1>);
integer idxdsize = if imm5<4> == '1' then 128 else 64;

if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;‘
integer elements = datasize DIV esize;
```

Assembler symbols

<T> For the scalar variant: is the element width specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

<T> For the vector variant: is an arrangement specifier, encoded in the imm5:Q field:

RESERVED when imm5 = x0000, Q = x

8B when imm5 = xxxx1, Q = 0

16B when imm5 = xxxx1, Q = 1

4H when imm5 = xxx10, Q = 0

8H when imm5 = xxx10, Q = 1

2S when imm5 = xx100, Q = 0

4S when imm5 = xx100, Q = 1

RESERVED when imm5 = x1000, Q = 0

2D when imm5 = x1000, Q = 1

<Ts> Is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

<V> Is the destination width specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<index> Is the element index encoded in the imm5 field:

RESERVED when imm5 = x0000

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

imm5<4> when imm5 = x1000

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

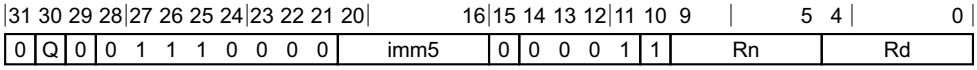
Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(datasize) result;
bits(esize) element;

element = Elem[operand, index, esize];
for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

C7.3.32 DUP (general)

Duplicate general-purpose register to vector



Advanced SIMD variant

```
DUP <Vd>.<T>, <R><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

// imm5<4:size+1> is IGNORED

if size == 3 && Q == '0' then ReservedValue();
integer esize = 8 << size;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the imm5:Q field:

RESERVED when imm5 = x0000, Q = x

8B when imm5 = xxxx1, Q = 0

16B when imm5 = xxxx1, Q = 1

4H when imm5 = xxx10, Q = 0

8H when imm5 = xxx10, Q = 1

2S when imm5 = xx100, Q = 0

4S when imm5 = xx100, Q = 1

RESERVED when imm5 = x1000, Q = 0

2D when imm5 = x1000, Q = 1

<R> Is the width specifier for the general-purpose source register, encoded in the imm5 field:

RESERVED when imm5 = x0000

W when imm5 = xxxx1

W when imm5 = xxx10

W when imm5 = xx100

X when imm5 = x1000

Unspecified bits in imm5 are ignored but should be set to zero by an assembler.

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the Rn field.

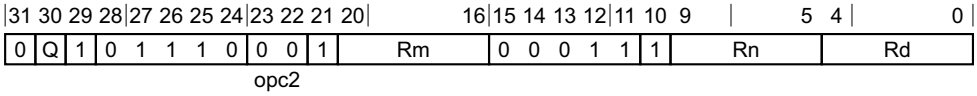
Operation

```
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = element;
V[d] = result;
```

C7.3.33 EOR (vector)

Bitwise exclusive OR (vector)



Three registers of the same type variant

```
EOR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

VBitOp op;

case opc2 of
    when '00' op = VBitOp_VEOR;
    when '01' op = VBitOp_VBSL;
    when '10' op = VBitOp_VBIT;
    when '11' op = VBitOp_VBIF;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1;
bits(datasize) operand2;
bits(datasize) operand3;
bits(datasize) operand4 = V[n];

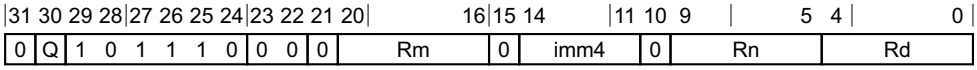
case op of
    when VBitOp_VEOR
        operand1 = V[m];
        operand2 = Zeros();
        operand3 = Ones();
    when VBitOp_VBSL
        operand1 = V[m];
        operand2 = operand1;
        operand3 = V[d];
    when VBitOp_VBIT
        operand1 = V[d];
        operand2 = operand1;
        operand3 = V[m];
    when VBitOp_VBIF
```

```
        operand1 = V[d];
        operand2 = operand1;
        operand3 = NOT(V[m]);

V[d] = operand1 EOR ((operand2 EOR operand4) AND operand3);
```

C7.3.34 EXT

Extract vector from pair of vectors



Advanced SIMD variant

```
EXT <Vd>.<T>, <Vn>.<T>, <Vm>.<T>, #<index>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if Q == '0' && imm4<3> == '1' then UnallocatedEncoding();

integer datasize = if Q == '1' then 128 else 64;
integer position = UInt(imm4) << 3;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

<index> Is the lowest numbered byte element to be extracted, encoded in the Q:imm4 field:

imm4<2:0> when Q = 0, imm4<3> = 0

RESERVED when Q = 0, imm4<3> = 1

imm4 when Q = 1, imm4<3> = x

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) hi = V[m];
bits(datasize) lo = V[n];
bits(datasize*2) concat = hi:lo;

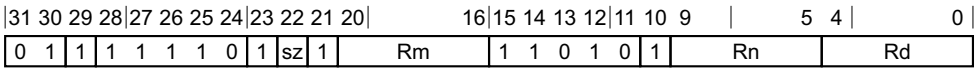
V[d] = concat<position+datasize-1:position>;
```

C7.3.35 FABD

Floating-point absolute difference (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar

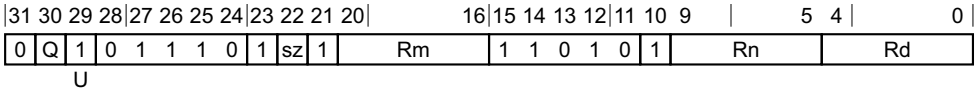


Scalar variant

```
FABD <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
boolean abs = TRUE;
```

Vector



Vector variant

```
FABD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<m> Is the number of the second SIMD&FP source register, encoded in the Rm field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation for all classes

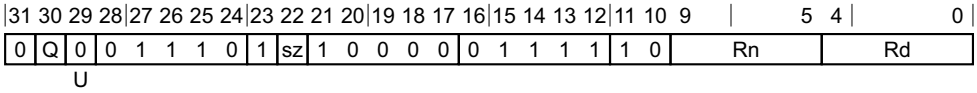
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) diff;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    diff = FPSub(element1, element2, FPCR);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;

V[d] = result;
```

C7.3.36 FABS (vector)

Floating-point absolute value (vector)



Vector variant

```
FABS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean neg = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation

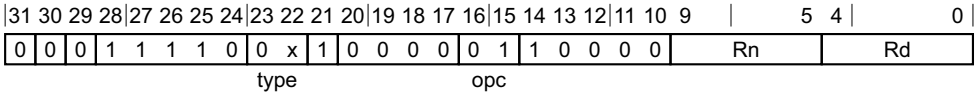
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    if neg then
        element = FPNeg(element);
    else
        element = FPAbs(element);
    Elem[result, e, esize] = element;

V[d] = result;
```

C7.3.37 FABS (scalar)

Floating-point absolute value (scalar): `Vd = abs(Vn)`



Single-precision variant (type = 00)

```
FABS <Sd>, <Sn>
```

Double-precision variant (type = 01)

```
FABS <Dd>, <Dn>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

FPUnaryOp fpop;
case opc of
    when '00' fpop = FPUnaryOp_MOV;
    when '01' fpop = FPUnaryOp_ABS;
    when '10' fpop = FPUnaryOp_NEG;
    when '11' fpop = FPUnaryOp_SQRT;
```

Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Dn>	Is the 64-bit name of the SIMD&FP source register, encoded in the Rn field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the Rn field.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) result;
bits(datasize) operand = V[n];

case fpop of
    when FPUnaryOp_MOV  result = operand;
    when FPUnaryOp_ABS  result = FPAbs(operand);
    when FPUnaryOp_NEG  result = FPNeg(operand);
    when FPUnaryOp_SQRT result = FPSqrt(operand, FPCR);

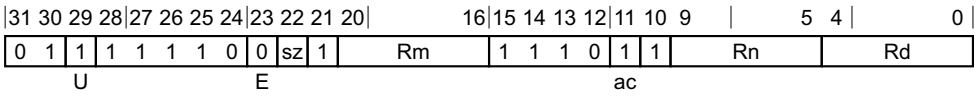
V[d] = result;
```

C7.3.38 FACGE

Floating-point absolute compare greater than or equal (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
FACGE <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

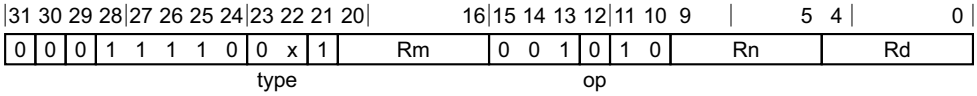
    else
        element1 = Elem[operand1, e, esize];
        element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPAdd(element1, element2, FPCR);

V[d] = result;
```

C7.3.41 FADD (scalar)

Floating-point add (scalar): `Vd = Vn + Vm`



Single-precision variant (type = 00)

```
FADD <Sd>, <Sn>, <Sm>
```

Double-precision variant (type = 01)

```
FADD <Dd>, <Dn>, <Dm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean sub_op = (op == '1');
```

Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.

Operation

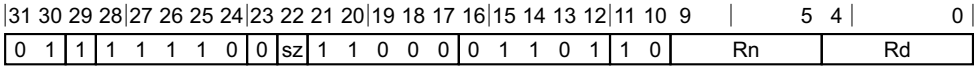
```
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

if sub_op then
    result = FPSub(operand1, operand2, FPCR);
else
    result = FPAdd(operand1, operand2, FPCR);

V[d] = result;
```

C7.3.42 FADDP (scalar)

Floating-point add pair of elements (scalar)



Advanced SIMD variant

```
FADDP <V><d>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize * 2;
integer elements = 2;

ReduceOp op = ReduceOp_FADD;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the sz field:

- **S** when sz = 0
- **D** when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<T> Is the source arrangement specifier, encoded in the sz field:

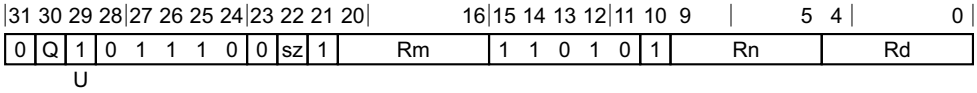
- **2S** when sz = 0
- **2D** when sz = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(op, operand, esize);
```

C7.3.43 FADDP (vector)

Floating-point add pairwise (vector)



Three registers of the same type variant

```
FADDP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean pair = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

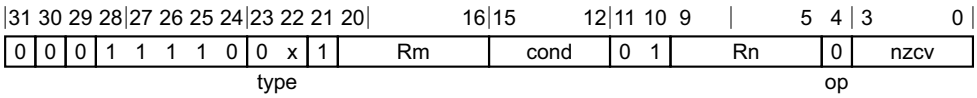
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    if pair then
        element1 = Elem[concat, 2*e, esize];
        element2 = Elem[concat, (2*e)+1, esize];
    else
        element1 = Elem[operand1, e, esize];
        element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPAdd(element1, element2, FPCR);

V[d] = result;
```

C7.3.44 FCCMP

Floating-point conditional quiet compare (scalar), setting condition flags to result of comparison or an immediate value: `flags = if cond then compareQuiet(Vn,Vm) else #nzcv`



Single-precision variant (type = 00)

```
FCCMP <Sn>, <Sm>, #<nzcv>, <cond>
```

Double-precision variant (type = 01)

```
FCCMP <Dn>, <Dm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean signal_all_nans = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
```

Assembler symbols

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
<cond>	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
CheckFPAdvSIMDEnabled64();

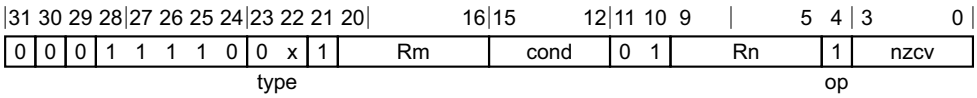
bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = V[m];

if ConditionHolds(condition) then
    flags = FPCompare(operand1, operand2, signal_all_nans, FPCR);
PSTATE.<N,Z,C,V> = flags;
```

C7.3.45 FCCMPE

Floating-point conditional signaling compare (scalar), setting condition flags to result of comparison or an immediate value: `flags = if cond then compareSignaling(Vn,Vm) else #nzcv`



Single-precision variant (type = 00)

```
FCCMPE <Sn>, <Sm>, #<nzcv>, <cond>
```

Double-precision variant (type = 01)

```
FCCMPE <Dn>, <Dm>, #<nzcv>, <cond>

integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean signal_all_nans = (op == '1');
bits(4) condition = cond;
bits(4) flags = nzcv;
```

Assembler symbols

<Dn>	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
<Sn>	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.
<nzcv>	Is the flag bit specifier, an immediate in the range 0 to 15, giving the alternative state for the 4-bit NZCV condition flags, encoded in the nzcv field.
<cond>	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = V[m];

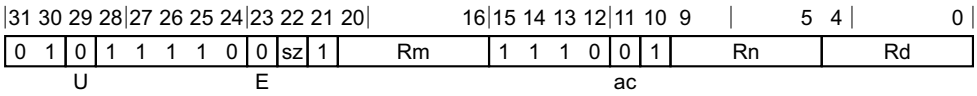
if ConditionHolds(condition) then
    flags = FPCompare(operand1, operand2, signal_all_nans, FPCR);
PSTATE.<N,Z,C,V> = flags;
```

C7.3.46 FCMEQ (register)

Floating-point compare equal (vector), setting destination vector element to all ones if the condition holds, else zero

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
FCMEQ <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
CompareOp cmp;
boolean abs;

case E:U:ac of
    when '000' cmp = CompareOp_EQ; abs = FALSE;
    when '010' cmp = CompareOp_GE; abs = FALSE;

```
CheckFPAdvSIMDEnabled64();

bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

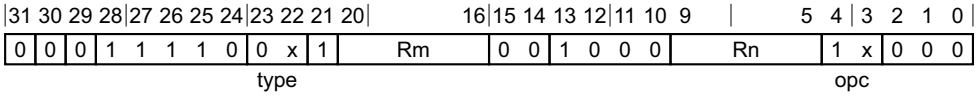
C7.3.55 FCMPE

Floating-point signaling compare (scalar): `flags = compareSignaling(Vn, Vm) // with register`



Single-precision variant (type = 00, opc = 10)

```
FCMPE <Sn>, <Sm>
```

Single-precision, zero variant (type = 00, Rm = (00000), opc = 11)

```
FCMPE <Sn>, #0.0
```

Double-precision variant (type = 01, opc = 10)

```
FCMPE <Dn>, <Dm>
```

Double-precision, zero variant (type = 01, Rm = (00000), opc = 11)

```
FCMPE <Dn>, #0.0
```

```
integer n = UInt(Rn);
integer m = UInt(Rm);   // ignored when opc<0> == '1'

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean signal_all_nans = (opc<1> == '1');
boolean cmp_with_zero = (opc<0> == '1');
```

Assembler symbols

<Dn>	For the double-precision variant: is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Dn>	For the double-precision, zero variant: is the 64-bit name of the SIMD&FP source register, encoded in the Rn field.
<Dm>	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
<Sn>	For the single-precision variant: is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
<Sn>	For the single-precision, zero variant: is the 32-bit name of the SIMD&FP source register, encoded in the Rn field.
<Sm>	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();

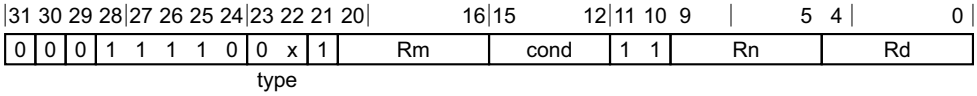
bits(datasize) operand1 = V[n];
bits(datasize) operand2;

operand2 = if cmp_with_zero then FPZero('0') else V[m];

PSTATE.<N,Z,C,V> = FPCompare(operand1, operand2, signal_all_nans, FPCR);
```

C7.3.56 FCSEL

Floating-point conditional select (scalar): `Vd = if cond then Vn else Vm`



Single-precision variant (type = 00)

```
FCSEL <Sd>, <Sn>, <Sm>, <cond>
```

Double-precision variant (type = 01)

```
FCSEL <Dd>, <Dn>, <Dm>, <cond>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

bits(4) condition = cond;
```

Assembler symbols

`<Dd>`	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Dn>`	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Dm>`	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
`<Sd>`	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Sn>`	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Sm>`	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.
`<cond>`	Is one of the standard conditions, encoded in the cond field in the standard way.

Operation

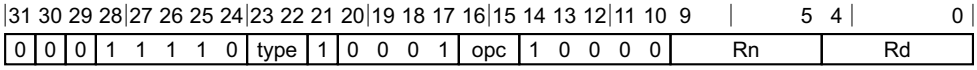
```
CheckFPAdvSIMDEnabled64();
bits(datasize) result;

result = if ConditionHolds(condition) then V[n] else V[m];

V[d] = result;
```

C7.3.57 FCVT

Floating-point convert precision (scalar): `Vd = convertFormat(Vn)`



Half-precision to single-precision variant (type = 11, opc = 00)

```
FCVT <Sd>, <Hn>
```

Half-precision to double-precision variant (type = 11, opc = 01)

```
FCVT <Dd>, <Hn>
```

Single-precision to half-precision variant (type = 00, opc = 11)

```
FCVT <Hd>, <Sn>
```

Single-precision to double-precision variant (type = 00, opc = 01)

```
FCVT <Dd>, <Sn>
```

Double-precision to half-precision variant (type = 01, opc = 11)

```
FCVT <Hd>, <Dn>
```

Double-precision to single-precision variant (type = 01, opc = 00)

```
FCVT <Sd>, <Dn>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);

if type == opc then UnallocatedEncoding();

integer srcsize;
case type of
    when '00' srcsize = 32;
    when '01' srcsize = 64;
    when '10' UnallocatedEncoding();
    when '11' srcsize = 16;
integer dstsize;
case opc of
    when '00' dstsize = 32;
    when '01' dstsize = 64;
    when '10' UnallocatedEncoding();
    when '11' dstsize = 16;
```

Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Hd>	Is the 16-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the Rn field.
<Sd>	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Hn>	Is the 16-bit name of the SIMD&FP source register, encoded in the Rn field.
<Dn>	Is the 64-bit name of the SIMD&FP source register, encoded in the Rn field.

Operation

```
CheckFPAdvSIMDEnabled64();

bits(dstsize) result;
bits(srcsize) operand = V[n];

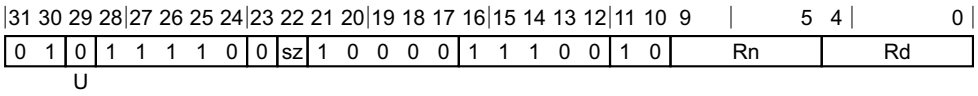
result = FPConvert(operand, FPCR);
V[d] = result;
```

C7.3.58 FCVTAS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to away (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

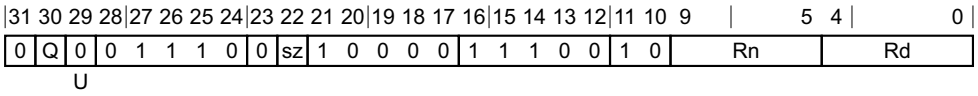
```
FCVTAS <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPRounding_TIEAWAY;
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTAS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPRounding_TIEAWAY;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1

```

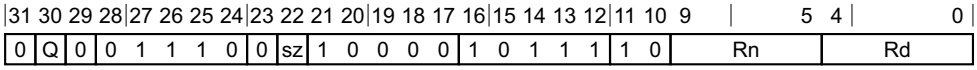
C7.3.62 FCVTL, FCVTL2

Floating-point convert to higher precision long (vector)



Vector variant

```
FCVTL{2} <Vd>.<Ta>, <Vn>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the sz field:

4S when sz = 0

2D when sz = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the sz:Q field:

4H when sz = 0, Q = 0

8H when sz = 0, Q = 1

2S when sz = 1, Q = 0

4S when sz = 1, Q = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;

for e = 0 to elements-1
    Elem[result, e, 2*esize] = FPConvert(Elem[operand, e, esize], FPCR);

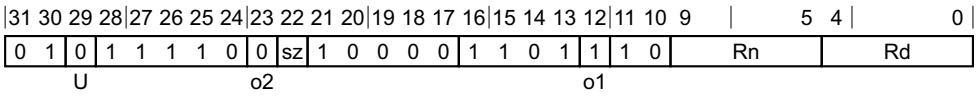
V[d] = result;
```

C7.3.63 FCVTMS (vector)

Floating-point convert to signed integer, rounding toward minus infinity (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

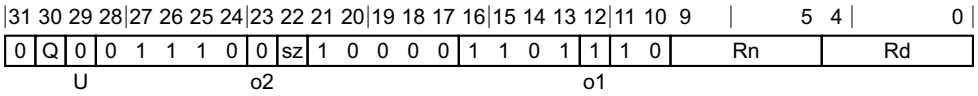
```
FCVTMS <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTMS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

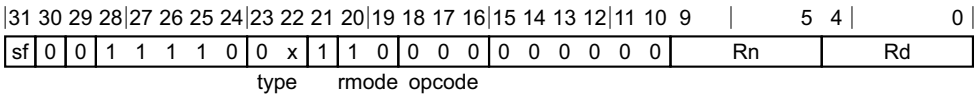
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.3.64 FCVTMS (scalar)

Floating-point convert to signed integer, rounding toward minus infinity (scalar):

```
Rd = signed_convertToIntegerExactTowardNegative(Vn)
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```

```

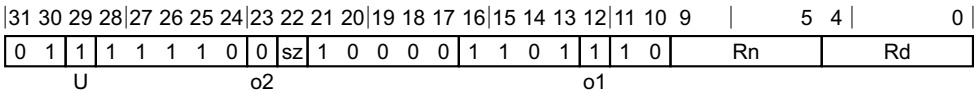
C7.3.65 FCVTMU (vector)

Floating-point convert to unsigned integer, rounding toward minus infinity (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

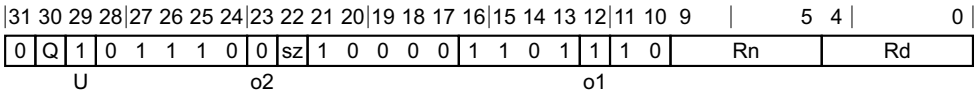
```
FCVTMU <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTMU <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

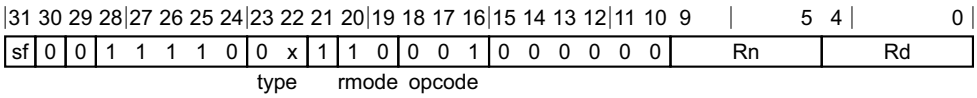
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.3.66 FCVTMU (scalar)

Floating-point convert to unsigned integer, rounding toward minus infinity (scalar):

```
Rd = unsigned_convertToIntegerExactTowardNegative(Vn)
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```
FCVTMU <Wd>, <Sn>
```

Single-precision to 64-bit variant (sf = 1, type = 00)

```
FCVTMU <Xd>, <Sn>
```

Double-precision to 32-bit variant (sf = 0, type = 01)

```
FCVTMU <Wd>, <Dn>
```

Double-precision to 64-bit variant (sf = 1, type = 01)

```
FCVTMU <Xd>, <Dn>

integer d = UInt(Rd);

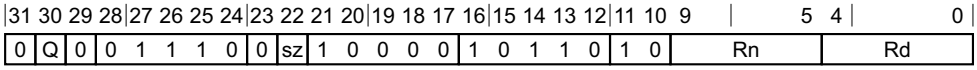
    when FPConvOp_MOV_ItoF
        intval = X[n];
        Vpart[d,part] = intval;
```

C7.3.67 FCVTN, FCVTN2

Floating-point convert to lower precision narrow (vector)



Vector variant

```
FCVTN{2} <Vd>.<Tb>, <Vn>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 16 << UInt(sz);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the sz:Q field:

4H when sz = 0, Q = 0

8H when sz = 0, Q = 1

2S when sz = 1, Q = 0

4S when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the sz field:

4S when sz = 0

2D when sz = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR);

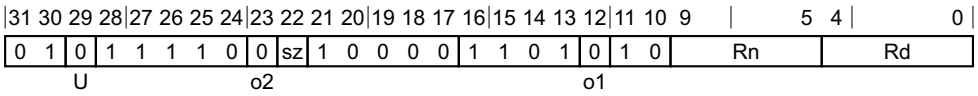
Vpart[d, part] = result;
```

C7.3.68 FCVTNS (vector)

Floating-point convert to signed integer, rounding to nearest with ties to even (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

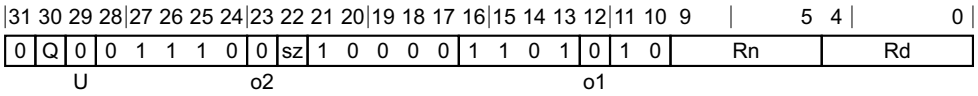
```
FCVTNS <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTNS <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

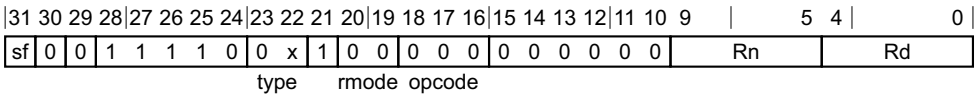
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.3.69 FCVTNS (scalar)

Floating-point convert to signed integer, rounding to nearest with ties to even (scalar):

```
Rd = signed_convertToIntegerExactTiesToEven(Vn)
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```
FCVTNS <Wd>, <Sn>
```

Single-precision to 64-bit variant (sf = 1, type = 00)

```

    when FPConvOp_MOV_ItoF
        intval = X[n];
        Vpart[d,part] = intval;
```

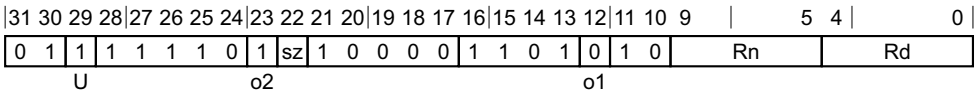
C7.3.74 FCVTPU (vector)

Floating-point convert to unsigned integer, rounding toward positive infinity (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

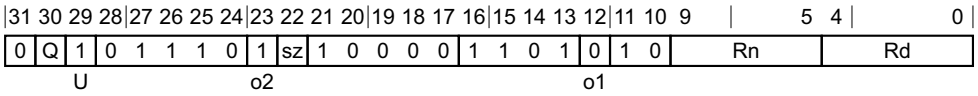
```
FCVTPU <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTPU <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

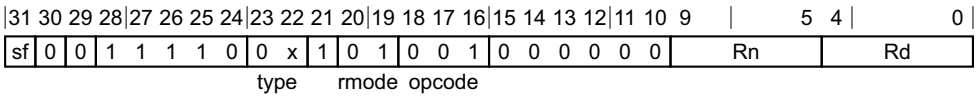
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.3.75 FCVTPU (scalar)

Floating-point convert to unsigned integer, rounding toward positive infinity (scalar):

```
Rd = unsigned_convertToIntegerExactTowardPositive(Vn)
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```
FCVTPU <Wd>, <Sn>
```

Single-precision to 64-bit variant (sf = 1, type = 00)

```
FCVTPU <Xd>, <Sn>
```

Double-precision to 32-bit variant (sf = 0, type = 01)

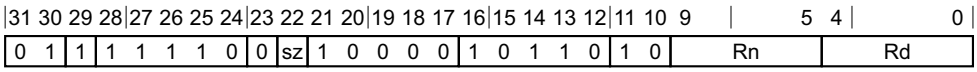
        Vpart[d,part] = intval;
```

C7.3.76 FCVTXN, FCVTXN2

Floating-point convert to lower precision narrow, rounding to odd (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



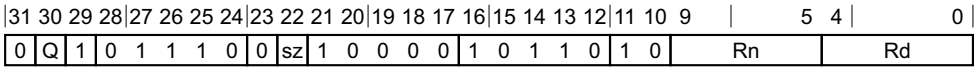
Scalar variant

```
FCVTXN <Vb><d>, <Va><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '0' then ReservedValue();
integer esize = 32;
integer datasize = esize;
integer elements = 1;
integer part = 0;
```

Vector



Vector variant

```
FCVTXN{2} <Vd>.<Tb>, <Vn>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '0' then ReservedValue();
integer esize = 32;
integer datasize = 64;
integer elements = 2;
integer part = UInt(Q);
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> — Is an arrangement specifier, encoded in the sz:Q field:

RESERVED when sz = 0, Q = x

2S when sz = 1, Q = 0

4S when sz = 1, Q = 1

<Vn> — Is the name of the SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the sz field:

RESERVED when sz = 0

2D when sz = 1

<Vb> Is the destination width specifier, encoded in the sz field:

RESERVED when sz = 0

S when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Va> Is the source width specifier, encoded in the sz field:

RESERVED when sz = 0

D when sz = 1

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = FPConvert(Elem[operand, e, 2*esize], FPCR, FPRounding_ODD);

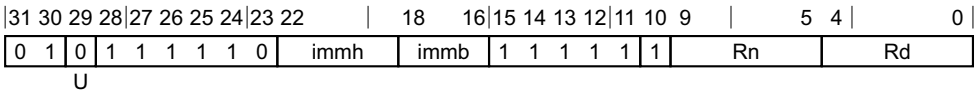
Vpart[d, part] = result;
```

C7.3.77 FCVTZS (vector, fixed-point)

Floating-point convert to signed fixed-point, rounding toward zero (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

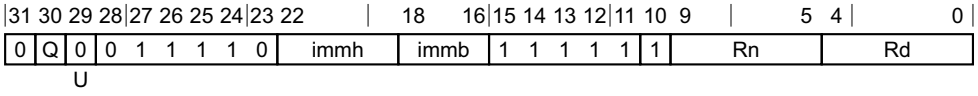
```
FCVTZS <V><d>, <V><n>, #<fbits>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '00xx' then ReservedValue();
integer esize = 32 << UInt(immh<3>);
integer datasize = esize;
integer elements = 1;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRounding_ZERO;
```

Vector



Vector variant

```
FCVTZS <Vd>.<T>, <Vn>.<T>, #<fbits>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh == '00xx' then ReservedValue();
if immh<3>:Q == '10' then ReservedValue();
integer esize = 32 << UInt(immh<3>);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRounding_ZERO;
```

Assembler symbols

<V> Is a width specifier, encoded in the immh field:

RESERVED when immh = 00xx

S when immh = 01xx

D when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

RESERVED when immh = 0001, Q = x

RESERVED when immh = 001x, Q = x

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = 0

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the immh:immb field:

RESERVED when immh = 00xx

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

<fbits> For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

RESERVED when immh = 0001

RESERVED when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand  = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, fracbits, unsigned, FPCR, rounding);

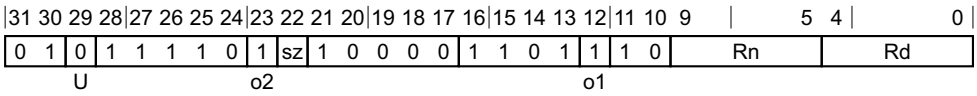
V[d] = result;
```

C7.3.78 FCVTZS (vector, integer)

Floating-point convert to signed integer, rounding toward zero (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
FCVTZS <V><d>, <V><n>

integer d = UInt(Rd);

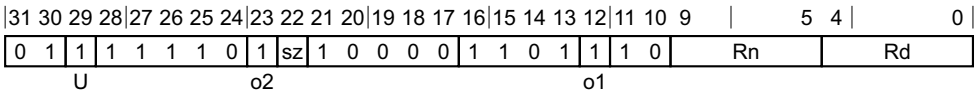
Floating-point convert to unsigned integer, rounding toward zero (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

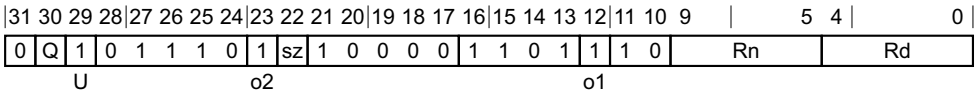
```
FCVTZU <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
FCVTZU <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

FPRounding rounding = FPDecodeRounding(o1:o2);
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

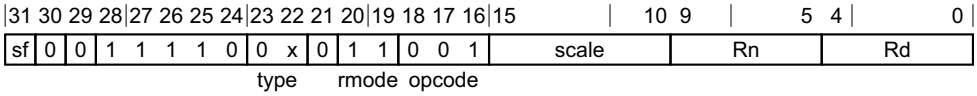
for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPToFixed(element, 0, unsigned, FPCR, rounding);

V[d] = result;
```

C7.3.83 FCVTZU (scalar, fixed-point)

Floating-point convert to unsigned fixed-point, rounding toward zero (scalar):

```
Rd = unsigned_convertToIntegerExactTowardZero(Vn*(2^fbits))
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```
FCVTZU <Wd>, <Sn>, #<fbits>
```

Single-precision to 64-bit variant (sf = 1, type = 00)

```
FCVTZU <Xd>, <Sn>, #<fbits>
```

Double-precision to 32-bit variant (sf = 0, type = 01)

```
FCVTZU <Wd>, <Dn>, #<fbits>
```

Double-precision to 64-bit variant (sf = 1, type = 01)

```
FCVTZU <Xd>, <Dn>, #<fbits>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPConvOp op;
FPRounding rounding;
boolean unsigned;

case type of
    when '00' fltsize = 32;
    when '01' fltsize = 64;
    when '1x' UnallocatedEncoding();

if sf == '0' && scale<5> == '0' then UnallocatedEncoding();
integer fracbits = 64 - UInt(scale);

case opcode<2:1>:rmode of
    when '00 11'        // FCVTZ
        rounding = FPRounding_ZERO;
        unsigned = (opcode<0> == '1');
        op = FPConvOp_CVT_FtoI;
    when '01 00'        // [US]CVTF
        rounding = FPRoundingMode(FPCR);
        unsigned = (opcode<0> == '1');
        op = FPConvOp_CVT_ItoF;
    otherwise
        UnallocatedEncoding();
```

Assembler symbols

<Wd>	Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.
<Xd>	Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.
<Sn>	Is the 32-bit name of the SIMD&FP source register, encoded in the Rn field.
<Dn>	Is the 64-bit name of the SIMD&FP source register, encoded in the Rn field.

<fbits> For the double-precision to 32-bit and single-precision to 32-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 32, encoded as 64 minus scale.

<fbits> For the double-precision to 64-bit and single-precision to 64-bit variant: is the number of bits after the binary point in the fixed-point destination, in the range 1 to 64, encoded as 64 minus scale.

Operation

```
CheckFPAdvSIMDEnabled64();

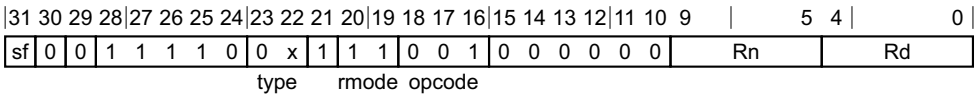
bits(fltsize) fltval;
bits(intsize) intval;

case op of
    when FPConvOp_CVT_FtoI
        fltval = V[n];
        intval = FPToFixed(fltval, fracbits, unsigned, FPCR, rounding);
        X[d] = intval;
    when FPConvOp_CVT_ItoF
        intval = X[n];
        fltval = FixedToFP(intval, fracbits, unsigned, FPCR, rounding);
        V[d] = fltval;
```

C7.3.84 FCVTZU (scalar, integer)

Floating-point convert to unsigned integer, rounding toward zero (scalar):

```
Rd = unsigned_convertToIntegerExactTowardZero(Vn)
```



Single-precision to 32-bit variant (sf = 0, type = 00)

```
FCVTZU <Wd>, <Sn>
```

Single-precision to 64-bit variant (sf = 1, type = 00)

```
FCVTZU <Xd>, <Sn>
```

Double-precision to 32-bit variant (sf = 0, type = 01)

```
FCVTZU <Wd>, <Dn>
```

Double-precision to 64-bit variant (sf = 1, type = 01)

```
FCVTZU <Xd>, <Dn>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer intsize = if sf == '1' then 64 else 32;
integer fltsize;
FPConvOp op;

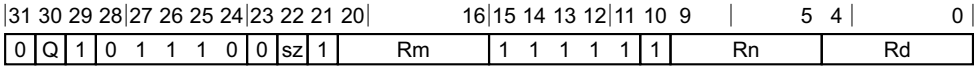
    when FPConvOp_MOV_ItoF
        intval = X[n];
        Vpart[d,part] = intval;
```

C7.3.85 FDIV (vector)

Floating-point divide (vector)



Three registers of the same type variant

```
FDIV <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

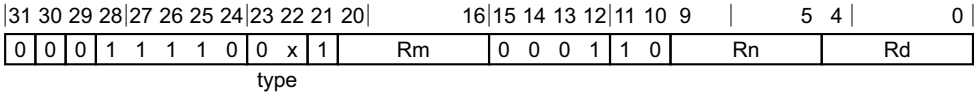
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, esize] = FPDiv(element1, element2, FPCR);

V[d] = result;
```

C7.3.86 FDIV (scalar)

Floating-point divide (scalar): `Vd = Vn / Vm`



Single-precision variant (type = 00)

```
FDIV <Sd>, <Sn>, <Sm>
```

Double-precision variant (type = 01)

```
FDIV <Dd>, <Dn>, <Dm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();
```

Assembler symbols

`<Dd>`	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Dn>`	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Dm>`	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
`<Sd>`	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Sn>`	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Sm>`	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.

Operation

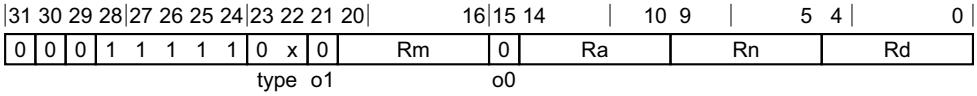
```
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

result = FPDiv(operand1, operand2, FPCR);

V[d] = result;
```

C7.3.87 FMADD

Floating-point fused multiply-add (scalar): `Vd = Va + Vn*Vm`



Single-precision variant (type = 00)

```
FMADD <Sd>, <Sn>, <Sm>, <Sa>
```

Double-precision variant (type = 01)

```
FMADD <Dd>, <Dn>, <Dm>, <Da>

integer d = UInt(Rd);
integer a = UInt(Ra);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean opa_neg = (o1 == '1');
boolean op1_neg = (o0 != o1);
```

Assembler symbols

`<Dd>` Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.

`<Dn>` Is the 64-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the Rn field.

`<Dm>` Is the 64-bit name of the second SIMD&FP source register holding the multiplier, encoded in the Rm field.

`<Da>` Is the 64-bit name of the third SIMD&FP source register holding the addend, encoded in the Ra field.

`<Sd>` Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.

`<Sn>` Is the 32-bit name of the first SIMD&FP source register holding the multiplicand, encoded in the Rn field.

`<Sm>` Is the 32-bit name of the second SIMD&FP source register holding the multiplier, encoded in the Rm field.

`<Sa>` Is the 32-bit name of the third SIMD&FP source register holding the addend, encoded in the Ra field.

Operation

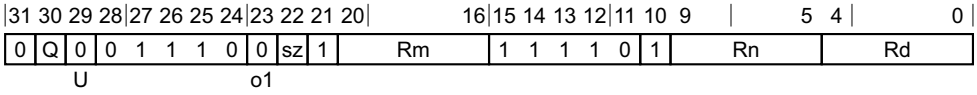
```
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operanda = V[a];
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
```

```
if opa_neg then operanda = FPNeg(operanda);
if op1_neg then operand1 = FPNeg(operand1);
result = FPMulAdd(operanda, operand1, operand2, FPCR);

V[d] = result;
```

C7.3.88 FMAX (vector)

Floating-point maximum (vector)



Three registers of the same type variant

```
FMAX <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();

    when FPMaxMinOp_MINNUM result = FPMinNum(operand1, operand2, FPCR);

V[d] = result;
```

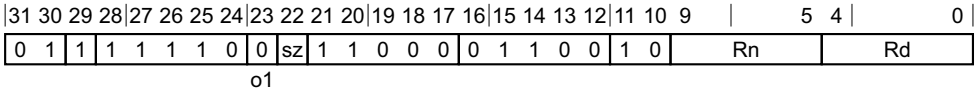
C7.3.92 FMAXNMP (scalar)

Floating-point maximum number of pair of elements (scalar)



Advanced SIMD variant

```
FMAXNMP <V><d>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize * 2;
integer elements = 2;

ReduceOp op = if o1 == '1' then ReduceOp_FMINNUM else ReduceOp_FMAXNUM;
```

Assembler symbols

<V> Is the destination width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<T> Is the source arrangement specifier, encoded in the sz field:

2S when sz = 0

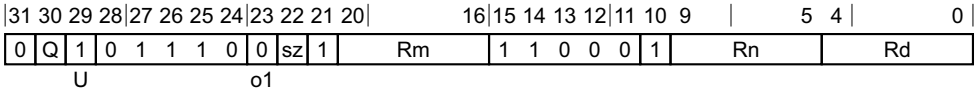
2D when sz = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
V[d] = Reduce(op, operand, esize);
```

C7.3.93 FMAXNMP (vector)

Floating-point maximum number pairwise (vector)



Three registers of the same type variant

```
FMAXNMP <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean pair = (U == '1');
boolean minimum = (o1 == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(2*datasize) concat = operand2:operand1;

V[d] = Reduce(op, operand, esize);
```

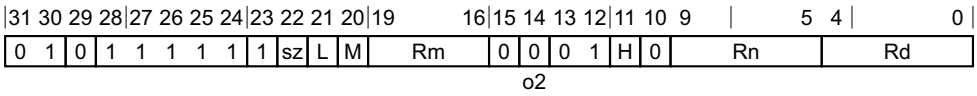
C7.3.108 FMLA (by element)

Floating-point fused multiply-add to accumulator (by element)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

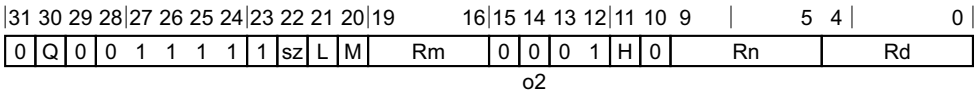
```
FMLA <V><d>, <V><n>, <Vm>.<Ts>[<index>]

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi = M;
case sz:L of
    when '0x' index = UInt(H:L);
    when '10' index = UInt(H);
    when '11' UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (o2 == '1');
```

Vector



Vector variant

```
FMLA <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi = M;
case sz:L of
    when '0x' index = UInt(H:L);
    when '10' index = UInt(H);
    when '11' UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (o2 == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q:sz field:

2S when Q = 0, sz = 0

RESERVED when Q = 0, sz = 1

4S when Q = 1, sz = 0

2D when Q = 1, sz = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> For the scalar variant: is the name of the SIMD&FP source register, encoded in the M:Rm fields.

<Vm> For the vector variant: is the name of the second SIMD&FP source register, encoded in the M:Rm fields.

<Ts> For the scalar variant: is the element width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<Ts> For the vector variant: is an element size specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<index> For the scalar variant: is the element index, encoded in the sz:L:H field:

H:L when sz = 0, L = x

H when sz = 1, L = 0

RESERVED when sz = 1, L = 1

<index> For the vector variant: is the element index encoded in the sz:L:H field:

H:L when sz = 0, L = x

H when sz = 1, L = 0

RESERVED when sz = 1, L = 1

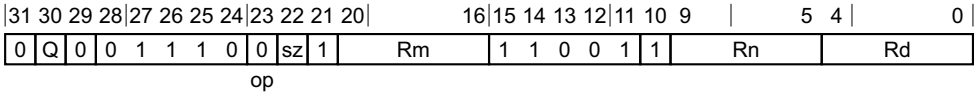
Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2 = Elem[operand2, index, esize];

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    if sub_op then element1 = FPNeg(element1);
    Elem[result, e, esize] = FPMulAdd(Elem[operand3, e, esize], element1, element2, FPCR);
V[d] = result;
```

C7.3.109 FMLA (vector)

Floating-point fused multiply-add to accumulator (vector)



Three registers of the same type variant

```
FMLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (op == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

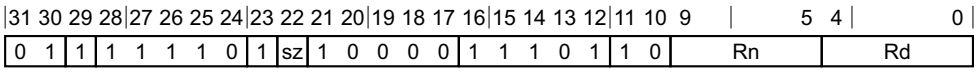
C7.3.144 FRSQRTE

Floating-point reciprocal square root estimate

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



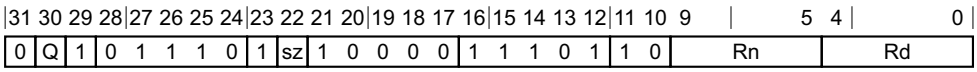
Scalar variant

```
FRSQRTE <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
```

Vector



Vector variant

```
FRSQRTE <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FPRSqrtEstimate(element, FPCR);

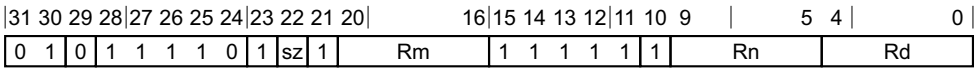
V[d] = result;
```

C7.3.145 FRSQRTS

Floating-point reciprocal square root step

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
FRSQRTS <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
```

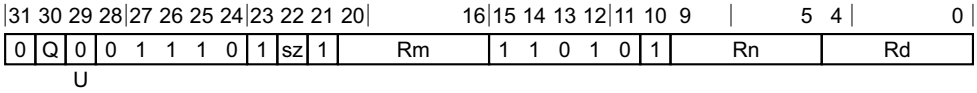
    when FPUnaryOp_SQRT result = FPSqrt(operand, FPCR);

V[d] = result;
```

C7.3.148 FSUB (vector)

Floating-point subtract (vector)



Three registers of the same type variant

```
FSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean abs = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

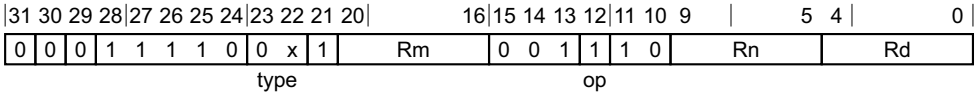
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) diff;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    diff = FPSub(element1, element2, FPCR);
    Elem[result, e, esize] = if abs then FPAbs(diff) else diff;

V[d] = result;
```

C7.3.149 FSUB (scalar)

Floating-point subtract (scalar): `Vd = Vn - Vm`



Single-precision variant (type = 00)

```
FSUB <Sd>, <Sn>, <Sm>
```

Double-precision variant (type = 01)

```
FSUB <Dd>, <Dn>, <Dm>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize;
case type of
    when '00' datasize = 32;
    when '01' datasize = 64;
    when '1x' UnallocatedEncoding();

boolean sub_op = (op == '1');
```

Assembler symbols

`<Dd>`	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Dn>`	Is the 64-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Dm>`	Is the 64-bit name of the second SIMD&FP source register, encoded in the Rm field.
`<Sd>`	Is the 32-bit name of the SIMD&FP destination register, encoded in the Rd field.
`<Sn>`	Is the 32-bit name of the first SIMD&FP source register, encoded in the Rn field.
`<Sm>`	Is the 32-bit name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) result;
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];

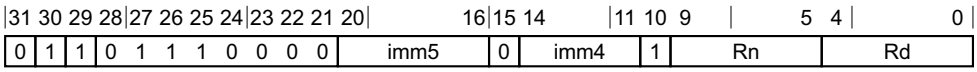
if sub_op then
    result = FPSub(operand1, operand2, FPCR);
else
    result = FPAdd(operand1, operand2, FPCR);

V[d] = result;
```

C7.3.150 INS (element)

Insert vector element from another vector element

This instruction is used by the alias MOV (element). The alias is always the preferred disassembly.



Advanced SIMD variant

```
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);
if size > 3 then UnallocatedEncoding();

integer dst_index = UInt(imm5<4:size+1>);
integer src_index = UInt(imm4<3:size>);
integer idxdsize = if imm4<3> == '1' then 128 else 64;
// imm4<size-1:0> is IGNORED

integer esize = 8 << size;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ts> Is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

<index1> Is the destination element index encoded in the imm5 field:

RESERVED when imm5 = x0000

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

imm5<4> when imm5 = x1000

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<index2> Is the source element index encoded in the imm5:imm4 field:

RESERVED when imm5 = x0000

imm4<3:0> when imm5 = xxxx1

imm4<3:1> when imm5 = xxx10

imm4<3:2> when imm5 = xx100

imm4<3> when imm5 = x1000

Unspecified bits in imm4 are ignored but should be set to zero by an assembler.

Operation

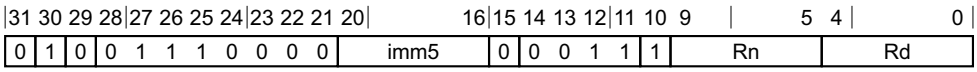
```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];
bits(128) result;

result = V[d];
Elem[result, dst_index, esize] = Elem[operand, src_index, esize];
V[d] = result;
```

C7.3.151 INS (general)

Insert vector element from general-purpose register

This instruction is used by the alias MOV (from general). The alias is always the preferred disassembly.



Advanced SIMD variant

```
INS <Vd>.<Ts>[<index>], <R><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size = LowestSetBit(imm5);

if size > 3 then UnallocatedEncoding();
integer index = UInt(imm5<4:size+1>);

integer esize = 8 << size;
integer datasize = 128;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ts> Is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

D when imm5 = x1000

<index> Is the element index encoded in the imm5 field:

RESERVED when imm5 = x0000

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

imm5<4> when imm5 = x1000

<R> Is the width specifier for the general-purpose source register, encoded in the imm5 field:

RESERVED when imm5 = x0000

W when imm5 = xxxx1

W when imm5 = xxx10

W when imm5 = xx100

X when imm5 = x1000

<n> Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the Rn field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(esize) element = X[n];
bits(datasize) result;

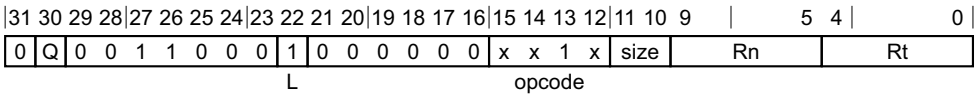
result = V[d];
Elem[result, index, esize] = element;
V[d] = result;
```

C7.3.152 LD1 (multiple structures)

Load multiple 1-element structures to one, two, three or four registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



One register variant (opcode = 0111)

```
LD1 {<Vt>.<T>}, [<Xn|SP>]
```

Two registers variant (opcode = 1010)

```
LD1 {<Vt>.<T>, <Vt2>.<T>}, [<Xn|SP>]
```

Three registers variant (opcode = 0110)

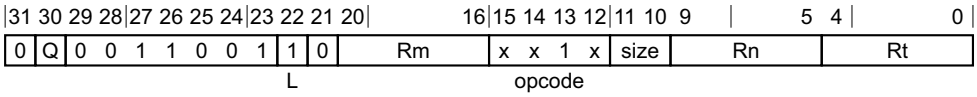
```
LD1 {<Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>}, [<Xn|SP>]
```

Four registers variant (opcode = 0010)

```
LD1 {<Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T>}, [<Xn|SP>]
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



One register, immediate offset variant (Rm = 11111, opcode = 0111)

```
LD1 { <Vt>.<T> }, [<Xn|SP>], <imm>
```

One register, register offset variant (Rm != 11111, opcode = 0111)

```
LD1 { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Two registers, immediate offset variant (Rm = 11111, opcode = 1010)

```
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Two registers, register offset variant (Rm != 11111, opcode = 1010)

```
LD1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Three registers, immediate offset variant (Rm = 11111, opcode = 0110)

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Three registers, register offset variant (Rm != 11111, opcode = 0110)

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Four registers, immediate offset variant (Rm = 11111, opcode = 0010)

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Four registers, register offset variant (Rm != 11111, opcode = 0010)

```
LD1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as Rt plus 2 modulo 32.

<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as Rt plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#8 when Q = 0

#16 when Q = 1

<imm> For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#16 when Q = 0

#32 when Q = 1

<imm> For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#24 when Q = 0

#48 when Q = 1

<imm> For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#32 when Q = 0

#64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;
```

```
integer rpt;    // number of iterations
integer selem;  // structure elements

case opcode of
    when '0000' rpt = 1; selem = 4;     // LD/ST4 (4 registers)
    when '0010' rpt = 4; selem = 1;     // LD/ST1 (4 registers)
    when '0100' rpt = 1; selem = 3;     // LD/ST3 (3 registers)
    when '0110' rpt = 3; selem = 1;     // LD/ST1 (3 registers)
    when '0111' rpt = 1; selem = 1;     // LD/ST1 (1 register)
    when '1000' rpt = 1; selem = 2;     // LD/ST2 (2 registers)
    when '1010' rpt = 2; selem = 1;     // LD/ST1 (2 registers)
    otherwise UnallocatedEncoding();

// .1D format only permitted with LD1 & ST1
if size:Q == '110' && selem != 1 then ReservedValue();
```

Operation for all classes

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(64) offs;
bits(datasize) rval;
integer e, r, s, tt;
constant integer ebytes = esize DIV 8;

if n == 31 then
    CheckSPAlignment();
    address = SP[];
else
    address = X[n];

offs = Zeros();
for r = 0 to rpt-1
    for e = 0 to elements-1
        tt = (t + r) MOD 32;
        for s = 0 to selem-1
            rval = V[tt];
            if memop == MemOp_LOAD then
                Elem[rval, e, esize] = Mem[address + offs, ebytes, AccType_VEC];
                V[tt] = rval;
            else // memop == MemOp_STORE
                Mem[address + offs, ebytes, AccType_VEC] = Elem[rval, e, esize];
            offs = offs + ebytes;
            tt = (tt + 1) MOD 32;

if wback then

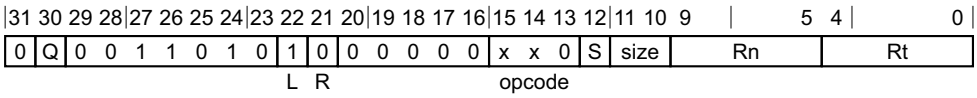
        offs = X[m];
    if n == 31 then
        SP[] = address + offs;
    else
        X[n] = address + offs;
```

C7.3.153 LD1 (single structure)

Load single 1-element structure to one lane of one register

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



8-bit variant (opcode = 000)

```
LD1 { <Vt>.B }[<index>], [<Xn|SP>]
```

16-bit variant (opcode = 010, size = x0)

```
LD1 { <Vt>.H }[<index>], [<Xn|SP>]
```

32-bit variant (opcode = 100, size = 00)

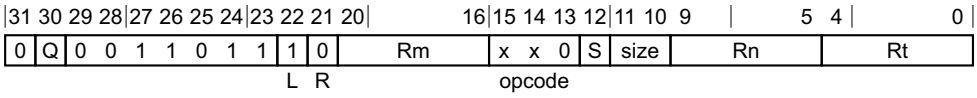
```
LD1 { <Vt>.S }[<index>], [<Xn|SP>]
```

64-bit variant (opcode = 100, S = 0, size = 01)

```
LD1 { <Vt>.D }[<index>], [<Xn|SP>]
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



8-bit, immediate offset variant (Rm = 11111, opcode = 000)

```
LD1 { <Vt>.B }[<index>], [<Xn|SP>], #1
```

8-bit, register offset variant (Rm != 11111, opcode = 000)

```
LD1 { <Vt>.B }[<index>], [<Xn|SP>], <Xm>
```

16-bit, immediate offset variant (Rm = 11111, opcode = 010, size = x0)

```
LD1 { <Vt>.H }[<index>], [<Xn|SP>], #2
```

16-bit, register offset variant (Rm != 11111, opcode = 010, size = x0)

```
LD1 { <Vt>.H }[<index>], [<Xn|SP>], <Xm>
```

32-bit, immediate offset variant (Rm = 11111, opcode = 100, size = 00)

```
LD1 { <Vt>.S }[<index>], [<Xn|SP>], #4
```

32-bit, register offset variant (Rm != 11111, opcode = 100, size = 00)

```
LD1 { <Vt>.S }[<index>], [<Xn|SP>], <Xm>
```

64-bit, immediate offset variant (Rm = 11111, opcode = 100, S = 0, size = 01)

```
LD1 { <Vt>.D }[<index>], [<Xn|SP>], #8
```

64-bit, register offset variant (Rm != 11111, opcode = 100, S = 0, size = 01)

```
LD1 { <Vt>.D }[<index>], [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.
<index>	For the 8-bit variant: is the element index, encoded in Q:S:size.
<index>	For the 16-bit variant: is the element index, encoded in Q:S:size<1>.
<index>	For the 32-bit variant: is the element index, encoded in Q:S.
<index>	For the 64-bit variant: is the element index, encoded in Q.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
integer scale = UInt(opcode<2:1>);

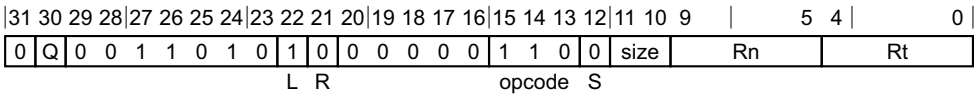
        SP[] = address + offs;
    else
        X[n] = address + offs;
```

C7.3.154 LD1R

Load single 1-element structure and replicate to all lanes (of one register)

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

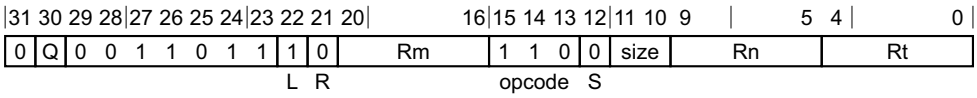


No offset variant

```
LD1R { <Vt>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
LD1R { <Vt>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> Is the post-index immediate offset, encoded in the size field:

#1 when size = 00

#2 when size = 01

#4 when size = 10

#8 when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```

    else
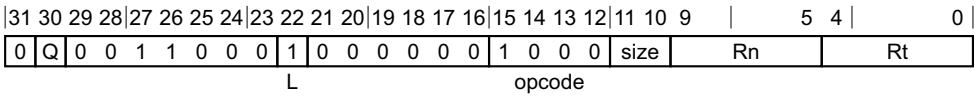
        X[n] = address + offs;
```

C7.3.155 LD2 (multiple structures)

Load multiple 2-element structures to two registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

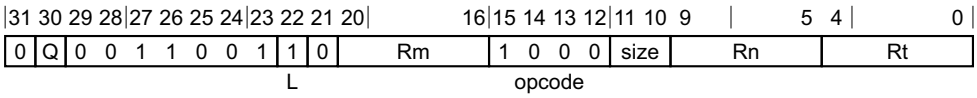


No offset variant

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
LD2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

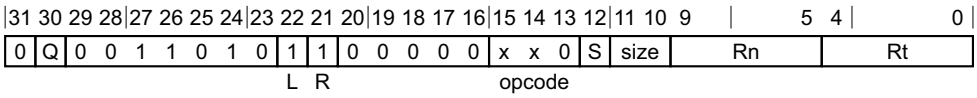
C7.3.156 LD2 (single structure)

Load single 2-element structure to one lane of two registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



8-bit variant (opcode = 000)

```
LD2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>]
```

16-bit variant (opcode = 010, size = x0)

```
LD2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>]
```

32-bit variant (opcode = 100, size = 00)

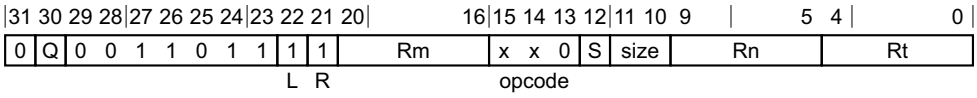
```
LD2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>]
```

64-bit variant (opcode = 100, S = 0, size = 01)

```
LD2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



8-bit, immediate offset variant (Rm = 11111, opcode = 000)

```
LD2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>], #2
```

8-bit, register offset variant (Rm != 11111, opcode = 000)

```
LD2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>], <Xm>
```

16-bit, immediate offset variant (Rm = 11111, opcode = 010, size = x0)

```
LD2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>], #4
```

16-bit, register offset variant (Rm != 11111, opcode = 010, size = x0)

```
LD2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>], <Xm>
```

32-bit, immediate offset variant (Rm = 11111, opcode = 100, size = 00)

```
LD2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>], #8
```

32-bit, register offset variant (Rm != 11111, opcode = 100, size = 00)

```
LD2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>], <Xm>
```

64-bit, immediate offset variant (Rm = 11111, opcode = 100, S = 0, size = 01)

```
LD2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>], #16
```

64-bit, register offset variant (Rm != 11111, opcode = 100, S = 0, size = 01)

```
LD2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.
<index>	For the 8-bit variant: is the element index, encoded in Q:S:size.
<index>	For the 16-bit variant: is the element index, encoded in Q:S:size<1>.
<index>	For the 32-bit variant: is the element index, encoded in Q:S.
<index>	For the 64-bit variant: is the element index, encoded in Q.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```

```

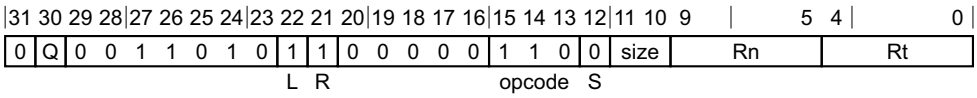
C7.3.157 LD2R

Load single 2-element structure and replicate to all lanes of two registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

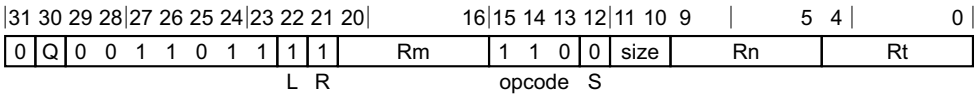


No offset variant

```
LD2R { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
LD2R { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
LD2R { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> Is the post-index immediate offset, encoded in the size field:

#2 when size = 00

#4 when size = 01

#8 when size = 10

#16 when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

    else
        X[n] = address + offs;
```

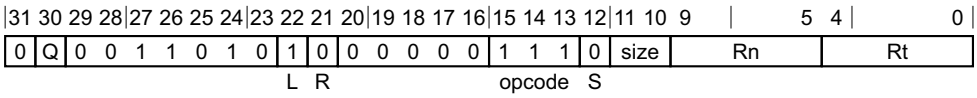
C7.3.160 LD3R

Load single 3-element structure and replicate to all lanes of three registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

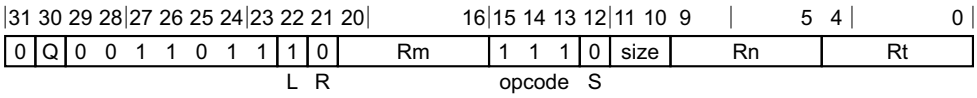


No offset variant

```
LD3R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
LD3R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
LD3R { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as Rt plus 2 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> Is the post-index immediate offset, encoded in the size field:

#3 when size = 00

#6 when size = 01

#12 when size = 10

#24 when size = 11

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
integer scale = UInt(opcode<2:1>);
integer selem = UInt(opcode<0>:R) + 1;
boolean replicate = FALSE;
integer index;

case scale of
    when 3
        // load and replicate

```

Assembler symbols

`<Bt>` Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Dt>` Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Ht>` Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Qt>` Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<St>` Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = 011

RESERVED when option = 10x

SXTW when option = 110

SXTX when option = 111

<amount> For the 8-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

[absent] when S = 0

#0 when S = 1

<amount> For the 16-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#1 when S = 1

<amount> For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#2 when S = 1

<amount> For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#3 when S = 1

<amount> For the 128-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#4 when S = 1

Shared decode for all variants

RESERVED when size = 00

0:Rm when size = 01

M:Rm when size = 10

RESERVED when size = 11

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the size field:

RESERVED when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<index> Is the element index encoded in the size:L:H:M field:

RESERVED when size = 00

H:L:M when size = 01

H:L when size = 10

RESERVED when size = 11

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1 * element2)<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;
V[d] = result;
```

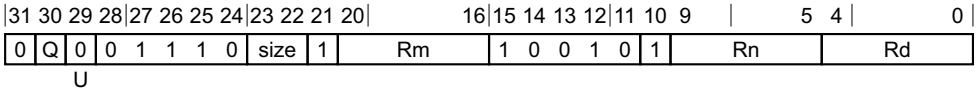
C7.3.171 MLA (vector)

Multiply-add to accumulator (vector)



Three registers of the same type variant

```
MLA <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

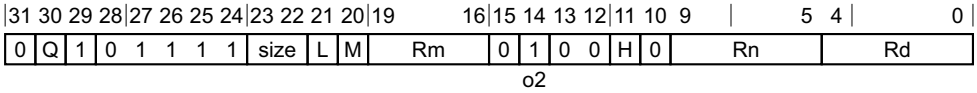
for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    product = (UInt(element1) * UInt(element2))<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
```

```
            Elem[result, e, esize] = Elem[operand3, e, esize] + product;

    V[d] = result;
```

C7.3.172 MLS (by element)

Multiply-subtract from accumulator (vector, by element)



Vector variant

```
MLS <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L);   Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (o2 == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

RESERVED when size = 00, Q = x

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the size:M:Rm field:

RESERVED when size = 00

0:Rm when size = 01

M:Rm when size = 10

RESERVED when size = 11

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the size field:

RESERVED when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<index> Is the element index encoded in the size:L:H:M field:

RESERVED when size = 00

H:L:M when size = 01

H:L when size = 10

RESERVED when size = 11

Operation

```
CheckFPAdvSIMDEnabled64();

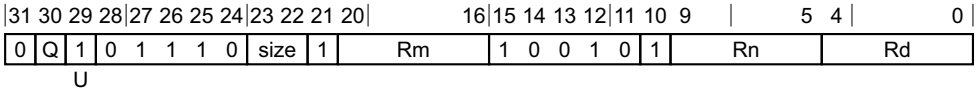
    else
        Elem[result, e, esize] = Elem[operand3, e, esize] + product;
V[d] = result;
```

C7.3.173 MLS (vector)

Multiply-subtract from accumulator (vector)



Three registers of the same type variant

```
MLS <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean sub_op = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) operand3 = V[d];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    product = (UInt(element1) * UInt(element2))<esize-1:0>;
    if sub_op then
        Elem[result, e, esize] = Elem[operand3, e, esize] - product;
    else
```

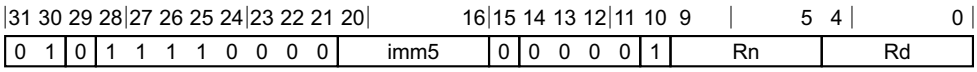
```
            Elem[result, e, esize] = Elem[operand3, e, esize] + product;

    V[d] = result;
```

C7.3.174 MOV (scalar)

Move vector element to scalar

This instruction is an alias of the DUP (element) instruction.



Scalar variant

```
MOV <V><d>, <Vn>.<T>[<index>]
```

is equivalent to

```
DUP <V><d>, <Vn>.<T>[<index>]
```

and is always the preferred disassembly.

Assembler symbols

<V> Is the destination width specifier, encoded in the imm5 field:

RESERVED when imm5 = `x0000`

B when imm5 = `xxxx1`

H when imm5 = `xxx10`

S when imm5 = `xx100`

D when imm5 = `x1000`

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<T> Is the element width specifier, encoded in the imm5 field:

RESERVED when imm5 = `x0000`

B when imm5 = `xxxx1`

H when imm5 = `xxx10`

S when imm5 = `xx100`

D when imm5 = `x1000`

<index> Is the element index encoded in the imm5 field:

RESERVED when imm5 = `x0000`

imm5<4:1> when imm5 = `xxxx1`

imm5<4:2> when imm5 = `xxx10`

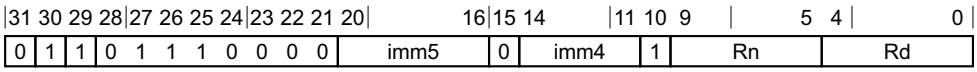
imm5<4:3> when imm5 = `xx100`

imm5<4> when imm5 = `x1000`

C7.3.175 MOV (element)

Move vector element to another vector element

This instruction is an alias of the INS (element) instruction.



Advanced SIMD variant

```
MOV <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

is equivalent to

```
INS <Vd>.<Ts>[<index1>], <Vn>.<Ts>[<index2>]
```

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<Ts>` Is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = `x0000`

B when imm5 = `xxxx1`

H when imm5 = `xxx10`

S when imm5 = `xx100`

D when imm5 = `x1000`

`<index1>` Is the destination element index encoded in the imm5 field:

RESERVED when imm5 = `x0000`

imm5<4:1> when imm5 = `xxxx1`

imm5<4:2> when imm5 = `xxx10`

imm5<4:3> when imm5 = `xx100`

imm5<4> when imm5 = `x1000`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

`<index2>` Is the source element index encoded in the imm5:imm4 field:

RESERVED when imm5 = `x0000`

imm4<3:0> when imm5 = `xxxx1`

imm4<3:1> when imm5 = `xxx10`

imm4<3:2> when imm5 = `xx100`

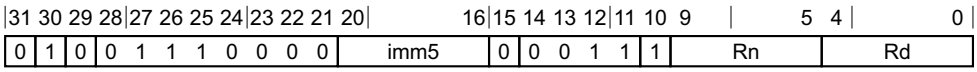
imm4<3> when imm5 = `x1000`

Unspecified bits in imm4 are ignored but should be set to zero by an assembler.

C7.3.176 MOV (from general)

Move general-purpose register to a vector element

This instruction is an alias of the INS (general) instruction.



Advanced SIMD variant

```
MOV <Vd>.<Ts>[<index>], <R><n>
```

is equivalent to

```
INS <Vd>.<Ts>[<index>], <R><n>
```

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<Ts>` Is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = `x0000`

B when imm5 = `xxxx1`

H when imm5 = `xxx10`

S when imm5 = `xx100`

D when imm5 = `x1000`

`<index>` Is the element index encoded in the imm5 field:

RESERVED when imm5 = `x0000`

imm5<4:1> when imm5 = `xxxx1`

imm5<4:2> when imm5 = `xxx10`

imm5<4:3> when imm5 = `xx100`

imm5<4> when imm5 = `x1000`

`<R>` Is the width specifier for the general-purpose source register, encoded in the imm5 field:

RESERVED when imm5 = `x0000`

W when imm5 = `xxxx1`

W when imm5 = `xxx10`

W when imm5 = `xx100`

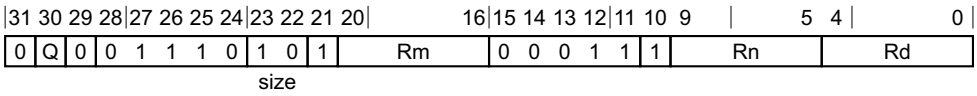
X when imm5 = `x1000`

`<n>` Is the number [0-30] of the general-purpose source register or ZR (31), encoded in the Rn field.

C7.3.177 MOV (vector)

Move vector

This instruction is an alias of the ORR (vector, register) instruction.



Three registers of the same type variant

`MOV <Vd>.<T>, <Vn>.<T>`

is equivalent to

`ORR <Vd>.<T>, <Vn>.<T>, <Vn>.<T>`

and is the preferred disassembly when `Rm == Rn`.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<T>` Is an arrangement specifier, encoded in the Q field:

8B when Q = `0`

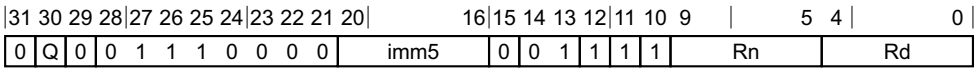
16B when Q = `1`

`<Vn>` Is the name of the first SIMD&FP source register, encoded in the Rn field.

C7.3.178 MOV (to general)

Move vector element to general-purpose register

This instruction is an alias of the UMOV instruction.



32-bit variant (Q = 0)

`MOV <Wd>, <Vn>.S[<index>]`
is equivalent to
`UMOV <Wd>, <Vn>.S[<index>]`
and is the preferred disassembly when `imm5 == 'xx100'`.

64-bit variant (Q = 1)

`MOV <Xd>, <Vn>.D[<index>]`
is equivalent to
`UMOV <Xd>, <Vn>.D[<index>]`
and is always the preferred disassembly.

Assembler symbols

`<Wd>` Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

`<Xd>` Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

`<index>` For the 32-bit variant: is the element index encoded in the imm5 field:

RESERVED when imm5 = `xx000`

imm5<4:1> when imm5 = `xxxx1`

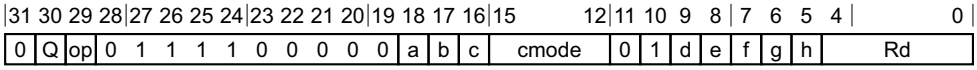
imm5<4:2> when imm5 = `xxx10`

imm5<4:3> when imm5 = `xx100`

`<index>` For the 64-bit variant: is the element index encoded in imm5<4>.

C7.3.179 MOVI

Move immediate (vector)



8-bit variant (op = 0, cmode = 1110)

```
MOVI <Vd>.<T>, #<imm8>{, LSL #0}
```

16-bit shifted immediate variant (op = 0, cmode = 10x0)

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifted immediate variant (op = 0, cmode = 0xx0)

```
MOVI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifting ones variant (op = 0, cmode = 110x)

```
MOVI <Vd>.<T>, #<imm8>, MSL #<amount>
```

64-bit scalar variant (Q = 0, op = 1, cmode = 1110)

```
MOVI <Dd>, #<imm>
```

64-bit vector variant (Q = 1, op = 1, cmode = 1110)

```
MOVI <Vd>.2D, #<imm>
```

```
integer Rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx00' operation = ImmediateOp_MOVI;
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx10' operation = ImmediateOp_ORR;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x00' operation = ImmediateOp_MOVI;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x10' operation = ImmediateOp_ORR;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x0' operation = ImmediateOp_MOVI;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11110' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UnallocatedEncoding();
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

<Dd>	Is the 64-bit name of the SIMD&FP destination register, encoded in the Rd field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the Rd field.

<imm> Is a 64-bit immediate 'aaaaaaaabbbbbbbbccccccccddddddddeeeeeeeeffffffffgggggggghhhhhhhh', encoded in a:b:c:d:e:f:g:h.

<T> For the 8-bit variant: is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<T> For the 16-bit variant: is an arrangement specifier, encoded in the Q field:

4H when Q = 0

8H when Q = 1

<T> For the 32-bit variant: is an arrangement specifier, encoded in the Q field:

2S when Q = 0

4S when Q = 1

<imm8> Is an 8-bit immediate encoded in a:b:c:d:e:f:g:h.

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in the cmode<1> field:

0 when cmode<1> = 0

8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

<amount> For the 32-bit shifted immediate variant: is the shift amount encoded in the cmode<2:1> field:

0 when cmode<2:1> = 00

8 when cmode<2:1> = 01

16 when cmode<2:1> = 10

24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

<amount> For the 32-bit shifting ones variant: is the shift amount encoded in the cmode<0> field:

8 when cmode<0> = 0

16 when cmode<0> = 1

Operation

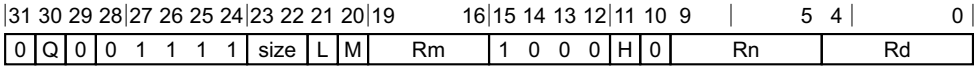
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

C7.3.180 MUL (by element)

Multiply (vector, by element)



Vector variant

```
MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<Ts>[<index>]

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L);   Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

RESERVED when size = 00, Q = x

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the size:M:Rm field:

RESERVED when size = 00

0:Rm when size = 01

M:Rm when size = 10

RESERVED when size = 11

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the size field:

RESERVED when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<index> Is the element index encoded in the size:L:H:M field:

RESERVED when size = 00

H:L:M when size = 01

H:L when size = 10

RESERVED when size = 11

Operation

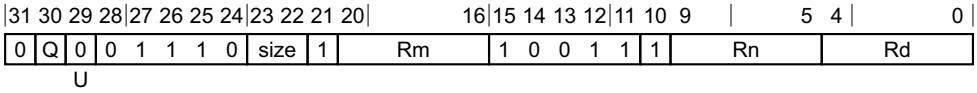
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(idxdsize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
bits(esize) product;

element2 = UInt(Elem[operand2, index, esize]);
for e = 0 to elements-1
    element1 = UInt(Elem[operand1, e, esize]);
    product = (element1 * element2)<esize-1:0>;
    Elem[result, e, esize] = product;

V[d] = result;
```

C7.3.181 MUL (vector)

Multiply (vector)



Three registers of the same type variant

```
MUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);

integer elements = datasize DIV esize;

boolean poly = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if poly then
        product = PolynomialMult(element1, element2)<esize-1:0>;
    else
        product = (UInt(element1) * UInt(element2))<esize-1:0>;
```

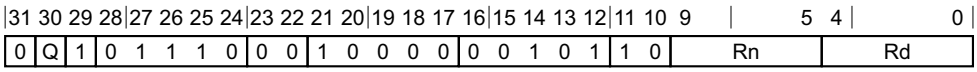
```
        Elem[result, e, esize] = product;

    V[d] = result;
```

C7.3.182 MVN

Bitwise NOT (vector)

This instruction is an alias of the NOT instruction.



Vector variant

`MVN <Vd>.<T>, <Vn>.<T>`

is equivalent to

`NOT <Vd>.<T>, <Vn>.<T>`

and is always the preferred disassembly.

Assembler symbols

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<T>` Is an arrangement specifier, encoded in the Q field:

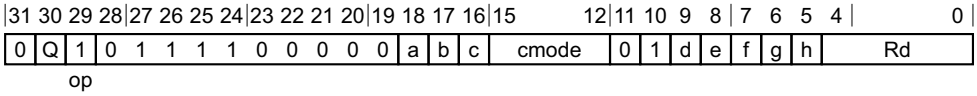
8B when Q = `0`

16B when Q = `1`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

C7.3.183 MVNI

Move inverted immediate (vector)



16-bit shifted immediate variant (cmode = 10x0)

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifted immediate variant (cmode = 0xx0)

```
MVNI <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit shifting ones variant (cmode = 110x)

```
MVNI <Vd>.<T>, #<imm8>, MSL #<amount>

integer Rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx00' operation = ImmediateOp_MOVI;
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx10' operation = ImmediateOp_ORR;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x00' operation = ImmediateOp_MOVI;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x10' operation = ImmediateOp_ORR;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x0' operation = ImmediateOp_MOVI;

    when '11110' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UnallocatedEncoding();
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the Q field:

4H when Q = 0

8H when Q = 1

<T> For the 32-bit variant: is an arrangement specifier, encoded in the Q field:

2S when Q = 0

4S when Q = 1

<imm8> Is an 8-bit immediate encoded in a:b:c:d:e:f:g:h.

<amount> For the 16-bit shifted immediate variant: is the shift amount encoded in the cmode<1> field:

0 when cmode<1> = 0

8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

<amount> For the 32-bit shifted immediate variant: is the shift amount encoded in the cmode<2:1> field:

0 when cmode<2:1> = 00

8 when cmode<2:1> = 01

16 when cmode<2:1> = 10

24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

<amount> For the 32-bit shifting ones variant: is the shift amount encoded in the cmode<0> field:

8 when cmode<0> = 0

16 when cmode<0> = 1

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

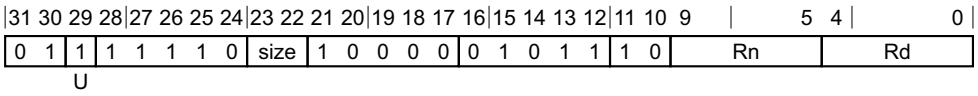
V[rd] = result;
```

C7.3.184 NEG (vector)

Negate (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

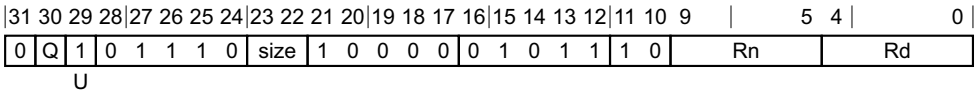
```
NEG <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean neg = (U == '1');
```

Vector



Vector variant

```
NEG <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean neg = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

RESERVED when size = 0x

RESERVED when size = 10

D when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B	when size = 00, Q = 1
4H	when size = 01, Q = 0
8H	when size = 01, Q = 1
2S	when size = 10, Q = 0
4S	when size = 10, Q = 1
RESERVED	when size = 11, Q = 0
2D	when size = 11, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
integer element;

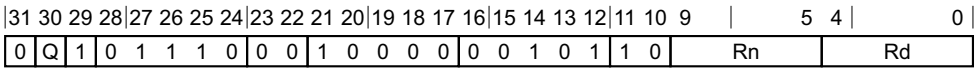
for e = 0 to elements-1
    element = SInt(Elem[operand, e, esize]);
    if neg then
        element = -element;
    else
        element = Abs(element);
    Elem[result, e, esize] = element<esize-1:0>;

V[d] = result;
```

C7.3.185 NOT

Bitwise NOT (vector)

This instruction is used by the alias MVN. The alias is always the preferred disassembly.



Vector variant

```
NOT <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation

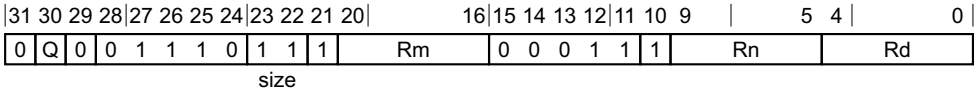
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = NOT(element);

V[d] = result;
```

C7.3.186 ORN (vector)

Bitwise inclusive OR NOT (vector)



Three registers of the same type variant

```
ORN <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean invert = (size<0> == '1');
LogicalOp op = if size<1> == '1' then LogicalOp_ORR else LogicalOp_AND;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

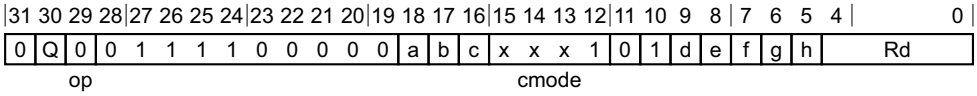
if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND
        result = operand1 AND operand2;
    when LogicalOp_ORR
        result = operand1 OR operand2;

V[d] = result;
```

C7.3.187 ORR (vector, immediate)

Bitwise inclusive OR (vector, immediate)



16-bit variant (cmode = 10x1)

```
ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}
```

32-bit variant (cmode = 0xx1)

```
ORR <Vd>.<T>, #<imm8>{, LSL #<amount>}

integer Rd = UInt(Rd);

integer datasize = if Q == '1' then 128 else 64;
bits(datasize) imm;
bits(64) imm64;

ImmediateOp operation;
case cmode:op of
    when '0xx00' operation = ImmediateOp_MOVI;
    when '0xx01' operation = ImmediateOp_MVNI;
    when '0xx10' operation = ImmediateOp_ORR;
    when '0xx11' operation = ImmediateOp_BIC;
    when '10x00' operation = ImmediateOp_MOVI;
    when '10x01' operation = ImmediateOp_MVNI;
    when '10x10' operation = ImmediateOp_ORR;
    when '10x11' operation = ImmediateOp_BIC;
    when '110x0' operation = ImmediateOp_MOVI;
    when '110x1' operation = ImmediateOp_MVNI;
    when '1110x' operation = ImmediateOp_MOVI;
    when '11110' operation = ImmediateOp_MOVI;
    when '11111'
        // FMOV Dn,#imm is in main FP instruction set
        if Q == '0' then UnallocatedEncoding();
        operation = ImmediateOp_MOVI;

imm64 = AdvSIMDExpandImm(op, cmode, a:b:c:d:e:f:g:h);
imm = Replicate(imm64, datasize DIV 64);
```

Assembler symbols

<Vd> Is the name of the SIMD&FP register, encoded in the Rd field.

<T> For the 16-bit variant: is an arrangement specifier, encoded in the Q field:

4H when Q = 0

8H when Q = 1

<T> For the 32-bit variant: is an arrangement specifier, encoded in the Q field:

2S when Q = 0

4S when Q = 1

<imm8> Is an 8-bit immediate encoded in a:b:c:d:e:f:g:h.

<amount> For the 16-bit variant: is the shift amount encoded in the cmode<1> field:

0 when cmode<1> = 0

8 when cmode<1> = 1

defaulting to 0 if LSL is omitted.

<amount> For the 32-bit variant: is the shift amount encoded in the cmode<2:1> field:

0 when cmode<2:1> = 00

8 when cmode<2:1> = 01

16 when cmode<2:1> = 10

24 when cmode<2:1> = 11

defaulting to 0 if LSL is omitted.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand;
bits(datasize) result;

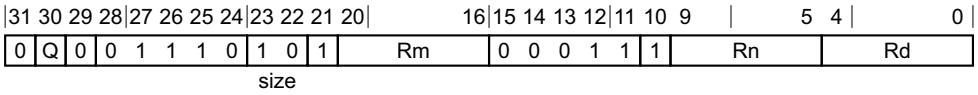
case operation of
    when ImmediateOp_MOVI
        result = imm;
    when ImmediateOp_MVNI
        result = NOT(imm);
    when ImmediateOp_ORR
        operand = V[rd];
        result = operand OR imm;
    when ImmediateOp_BIC
        operand = V[rd];
        result = operand AND NOT(imm);

V[rd] = result;
```

C7.3.188 ORR (vector, register)

Bitwise inclusive OR (vector, register)

This instruction is used by the alias MOV (vector). See the *Alias conditions* table for details of when each alias is preferred.



Three registers of the same type variant

```
ORR <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean invert = (size<0> == '1');
LogicalOp op = if size<1> == '1' then LogicalOp_ORR else LogicalOp_AND;
```

Alias conditions

Alias	is preferred when
MOV (vector)	`Rm == Rn`

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

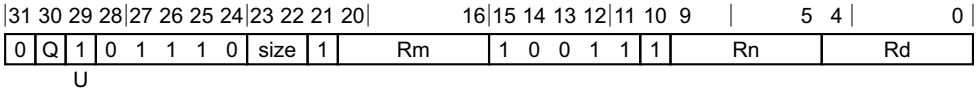
if invert then operand2 = NOT(operand2);

case op of
    when LogicalOp_AND
        result = operand1 AND operand2;
    when LogicalOp_ORR
        result = operand1 OR operand2;

V[d] = result;
```

C7.3.189 PMUL

Polynomial multiply



Three registers of the same type variant

```
PMUL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if U == '1' && size != '00' then ReservedValue();
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean poly = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

RESERVED when size = 01, Q = x

RESERVED when size = 1x, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

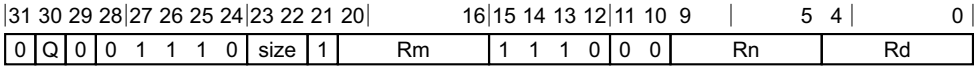
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;
bits(esize) product;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if poly then
        product = PolynomialMult(element1, element2)<esize-1:0>;
    else
        product = (UInt(element1) * UInt(element2))<esize-1:0>;
    Elem[result, e, esize] = product;

V[d] = result;
```

C7.3.190 PMULL, PMULL2

Polynomial multiply long



Three registers, not all the same type variant

```
PMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '01' || size == '10' then ReservedValue();
if size == '11' && ! HaveCryptoExt() then UnallocatedEncoding();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

RESERVED when size = 01

RESERVED when size = 10

1Q when size = 11

The '1Q' arrangement is only allocated in an implementation that includes the Cryptographic Extension, and is otherwise RESERVED.

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

RESERVED when size = 01, Q = x

RESERVED when size = 10, Q = x

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

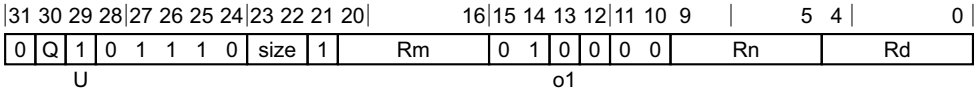
```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    Elem[result, e, 2*esize] = PolynomialMult(element1, element2);

V[d] = result;
```

C7.3.191 RADDHN, RADDHN2

Rounding add returning high narrow



Three registers, not all the same type variant

```
RADDHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

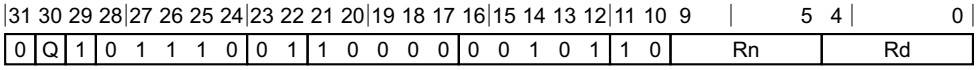
```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize)   result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

Vpart[d, part] = result;
```

C7.3.192 RBIT (vector)

Reverse bit order (vector)



Vector variant

```
RBIT <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation

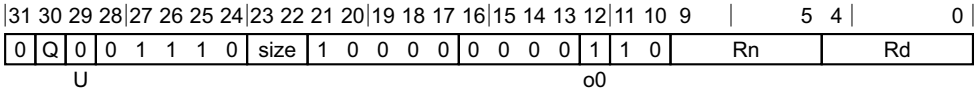
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(esize) element;
bits(esize) rev;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    for i = 0 to esize-1
        rev<esize-1-i> = element<i>;
    Elem[result, e, esize] = rev;

V[d] = result;
```

C7.3.193 REV16 (vector)

Reverse elements in 16-bit halfwords (vector)



Vector variant

```
REV16 <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

// size=esize:   B(0), H(1), S(1), D(S)
integer esize = 8 << UInt(size);

integer elements = datasize DIV esize;

integer fracbits = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
FPRounding rounding = FPRoundingMode(FPCR);
```

Assembler symbols

<V> Is a width specifier, encoded in the immh field:

RESERVED when immh = 00xx

S when immh = 01xx

D when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

RESERVED when immh = 0001, Q = x

RESERVED when immh = 001x, Q = x

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = 0

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<fbits> For the scalar variant: is the number of fractional bits, in the range 1 to the operand width, encoded in the immh:immb field:

RESERVED when immh = 00xx

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

<fbits> For the vector variant: is the number of fractional bits, in the range 1 to the element width, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

RESERVED when immh = 0001

RESERVED when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand  = V[n];
bits(datasize) result;
bits(esize) element;

for e = 0 to elements-1
    element = Elem[operand, e, esize];
    Elem[result, e, esize] = FixedToFP(element, fracbits, unsigned, FPCR, rounding);

V[d] = result;
```

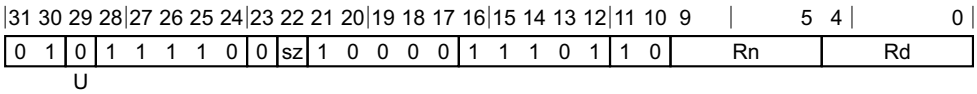
C7.3.208 SCVTF (vector, integer)

Signed integer convert to floating-point (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



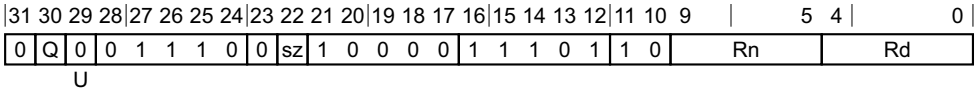
Scalar variant

```
SCVTF <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 32 << UInt(sz);
integer datasize = esize;
integer elements = 1;
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
SCVTF <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz:Q == '10' then ReservedValue();
integer esize = 32 << UInt(sz);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the sz field:

S when sz = 0

D when sz = 1

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = 0

2D when sz = 1, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
FPRounding rounding = FPRoundingMode(FPCR);
bits(esize) element;

for e = 0 to elements-1

bits(datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    sum = element1 + element2;
    Elem[result, e, esize] = sum<esize:1>;

V[d] = result;
```

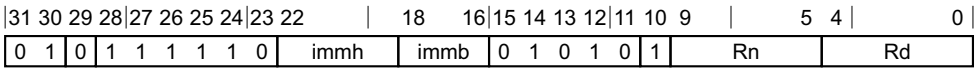
C7.3.222 SHL

Shift left (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

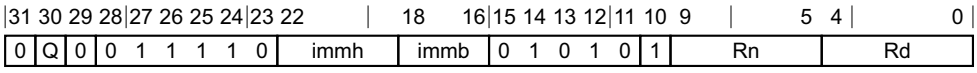
```
SHL <V><d>, <V><n>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immb) - esize;
```

Vector



Vector variant

```
SHL <Vd>.<T>, <Vn>.<T>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

<V> Is a width specifier, encoded in the immh field:

RESERVED when immh = 0xxx

D when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = 0

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the immh:immb field:

RESERVED when immh = 0xxx

(UInt(immh:immb)-64) when immh = 1xxx

<shift> For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

(UInt(immh:immb)-64) when immh = 1xxx

Operation for all classes

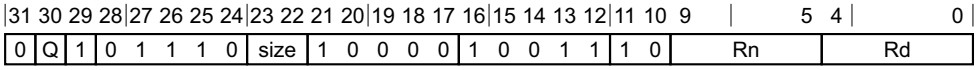
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand  = V[n];
bits(datasize) result;

for e = 0 to elements-1
    Elem[result, e, esize] = LSL(Elem[operand, e, esize], shift);

V[d] = result;
```

C7.3.223 SHLL, SHLL2

Shift left long (by element size)



Vector variant

```
SHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = esize;
boolean unsigned = FALSE; // Or TRUE without change of functionality
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<shift> Is the left shift amount, which must be equal to the source element width in bits, encoded in the size field:

8 when size = 00

16 when size = 01

32 when size = 10

RESERVED when size = 11

Operation

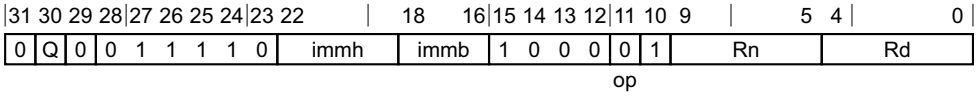
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(2*datasize) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

V[d] = result;
```

C7.3.224 SHRN, SHRN2

Shift right narrow (immediate)



Vector variant

```
SHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = x

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the immh field:

See Advanced SIMD modified immediate. when immh = 0000

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

RESERVED when immh = 1xxx

<shift> Is the right shift amount, in the range 1 to the destination element width in bits, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

RESERVED when immh = 1xxx

Operation

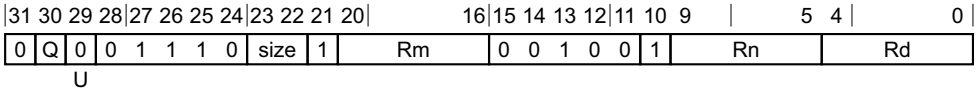
```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

for e = 0 to elements-1
    element = (UInt(Elem[operand, e, 2*esize]) + round_const) >> shift;
    Elem[result, e, esize] = element<esize-1:0>;

Vpart[d, part] = result;
```

C7.3.225 SHSUB

Signed halving subtract



Three registers of the same type variant

```
SHSUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
integer element1;
integer element2;
integer diff;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    diff = element1 - element2;
    Elem[result, e, esize] = diff<esize:1>;

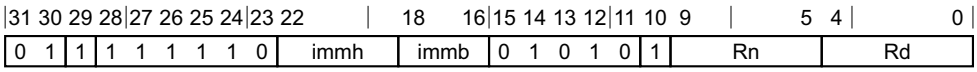
V[d] = result;
```

C7.3.226 SLI

Shift left and insert (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

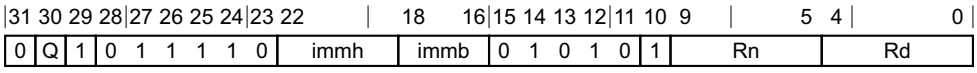
```
SLI <V><d>, <V><n>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = UInt(immh:immb) - esize;
```

Vector



Vector variant

```
SLI <Vd>.<T>, <Vn>.<T>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
```

Assembler symbols

<V> Is a width specifier, encoded in the immh field:

RESERVED when immh = 0xxx

D when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = 0

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<shift> For the scalar variant: is the left shift amount, in the range 0 to 63, encoded in the immh:immb field:

RESERVED when immh = 0xxx

(UInt(immh:immb)-64) when immh = 1xxx

<shift> For the vector variant: is the left shift amount, in the range 0 to the element width in bits minus 1, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(UInt(immh:immb)-8) when immh = 0001

```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

RESERVED when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

RESERVED when size = 00, Q = x

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

<Va> Is the destination width specifier, encoded in the size field:

RESERVED when size = 00

S when size = 01

D when size = 10

RESERVED when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<Vb> Is the source width specifier, encoded in the size field:

RESERVED when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<m> Is the number of the second SIMD&FP source register, encoded in the Rm field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
boolean sat;

for e = 0 to elements-1
    element1 = SInt(Elem[operand1, e, esize]);
    element2 = SInt(Elem[operand2, e, esize]);
    (product, sat) = SignedSatQ(2 * element1 * element2, 2*esize);
    Elem[result, e, 2*esize] = product;
    if sat then FPSR.QC = '1';

V[d] = result;
```

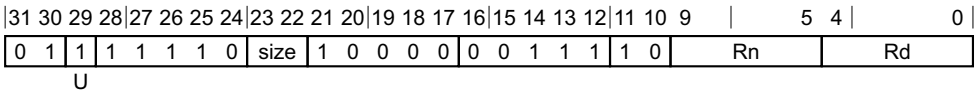
C7.3.250 SQNEG

Signed saturating negate

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

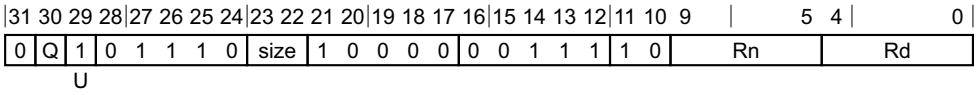
```
SQNEG <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean neg = (U == '1');
```

Vector



Vector variant

```
SQNEG <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean neg = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

- **B** when size = 00
- **H** when size = 01
- **S** when size = 10
- **D** when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

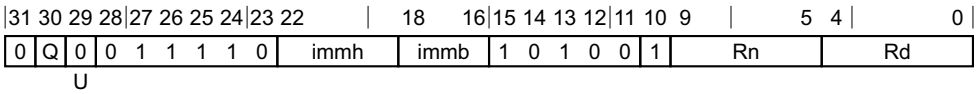
C7.3.270 SSHLL, SSHLL2

Signed shift left long (immediate)

This instruction is used by the alias SXTL. See the *Alias conditions* table for details of when each alias is preferred.



Vector variant

```
SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = UInt(immh:immb) - esize;
boolean unsigned = (U == '1');
```

Alias conditions

Alias	is preferred when
SXTL	`BitCount(immh) == 1 && immb == '000'`

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = `0`

[present] when Q = `1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<Ta>` Is an arrangement specifier, encoded in the immh field:

See Advanced SIMD modified immediate. when immh = `0000`

8H when immh = `0001`

4S when immh = `001x`

2D when immh = `01xx`

RESERVED when immh = `1xxx`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

`<Tb>` Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = `0000`, Q = `x`

8B when immh = `0001`, Q = `0`

16B when immh = `0001`, Q = `1`

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = x

<shift> Is the left shift amount, in the range 0 to the source element width in bits minus 1, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(UInt(immh:immb)-8) when immh = 0001

(UInt(immh:immb)-16) when immh = 001x

(UInt(immh:immb)-32) when immh = 01xx

RESERVED when immh = 1xxx

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = Vpart[n, part];
bits(datasize*2) result;
integer element;

for e = 0 to elements-1
    element = Int(Elem[operand, e, esize], unsigned) << shift;
    Elem[result, e, 2*esize] = element<2*esize-1:0>;

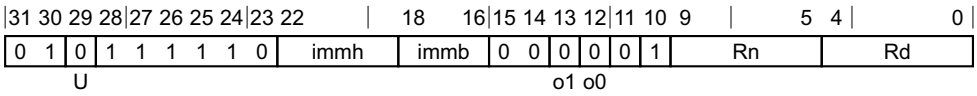
V[d] = result;
```

C7.3.271 SSHR

Signed shift right (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```

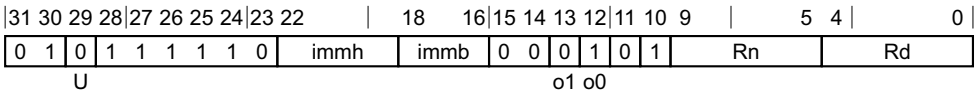
C7.3.272 SSRA

Signed shift right and accumulate (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

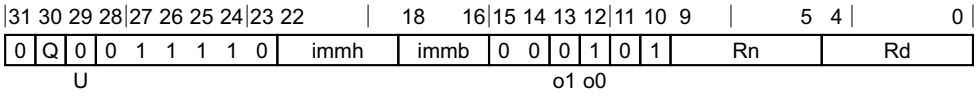
```
SSRA <V><d>, <V><n>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh<3> != '1' then ReservedValue();
integer esize = 8 << 3;
integer datasize = esize;
integer elements = 1;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Vector



Vector variant

```
SSRA <Vd>.<T>, <Vn>.<T>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3>:Q == '10' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

integer shift = (esize * 2) - UInt(immh:immb);
boolean unsigned = (U == '1');
boolean round = (o1 == '1');
boolean accumulate = (o0 == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the immh field:

RESERVED when immh = 0xxx

D when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = 0

2D when immh = 1xxx, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to 64, encoded in the immh:immb field:

RESERVED when immh = 0xxx

(128-UInt(immh:immb)) when immh = 1xxx

<shift> For the vector variant: is the right shift amount, in the range 1 to the element width in bits, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

(128-UInt(immh:immb)) when immh = 1xxx

Operation for all classes

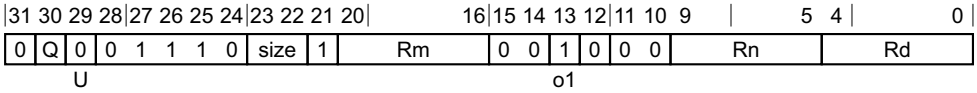
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand  = V[n];
bits(datasize) operand2;
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;

operand2 = if accumulate then V[d] else Zeros();
for e = 0 to elements-1
    element = (Int(Elem[operand, e, esize], unsigned) + round_const) >> shift;
    Elem[result, e, esize] = Elem[operand2, e, esize] + element<esize-1:0>;

V[d] = result;
```

C7.3.273 SSUBL, SSUBL2

Signed subtract long



Three registers, not all the same type variant

```
SSUBL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

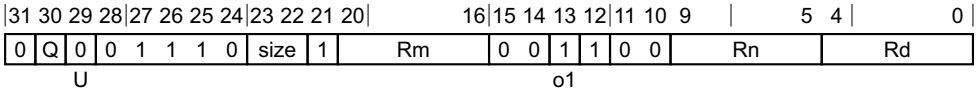
```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

V[d] = result;
```

C7.3.274 SSUBW, SSUBW2

Signed subtract wide



Three registers, not all the same type variant

```
SSUBW{2} <Vd>.<Ta>, <Vn>.<Ta>, <Vm>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) result;
integer element1;
integer element2;
integer sum;

for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, 2*esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    Elem[result, e, 2*esize] = sum<2*esize-1:0>;

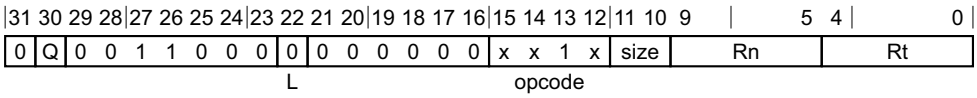
V[d] = result;
```

C7.3.275 ST1 (multiple structures)

Store multiple 1-element structures from one, two three or four registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



One register variant (opcode = 0111)

```
ST1 { <Vt>.<T> }, [<Xn|SP>]
```

Two registers variant (opcode = 1010)

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]
```

Three registers variant (opcode = 0110)

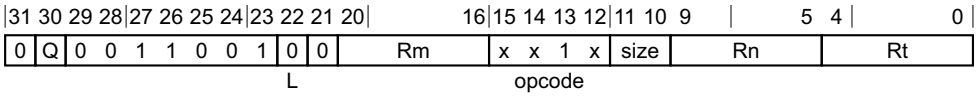
```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]
```

Four registers variant (opcode = 0010)

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>]
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



One register, immediate offset variant (Rm = 11111, opcode = 0111)

```
ST1 { <Vt>.<T> }, [<Xn|SP>], <imm>
```

One register, register offset variant (Rm != 11111, opcode = 0111)

```
ST1 { <Vt>.<T> }, [<Xn|SP>], <Xm>
```

Two registers, immediate offset variant (Rm = 11111, opcode = 1010)

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Two registers, register offset variant (Rm != 11111, opcode = 1010)

```
ST1 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>
```

Three registers, immediate offset variant (Rm = 11111, opcode = 0110)

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Three registers, register offset variant (Rm != 11111, opcode = 0110)

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>
```

Four registers, immediate offset variant (Rm = 11111, opcode = 0010)

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <imm>
```

Four registers, register offset variant (Rm != 11111, opcode = 0010)

```
ST1 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T>, <Vt4>.<T> }, [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

1D when size = 11, Q = 0

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

<Vt3> Is the name of the third SIMD&FP register to be transferred, encoded as Rt plus 2 modulo 32.

<Vt4> Is the name of the fourth SIMD&FP register to be transferred, encoded as Rt plus 3 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> For the one register, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#8 when Q = 0

#16 when Q = 1

<imm> For the two registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#16 when Q = 0

#32 when Q = 1

<imm> For the three registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#24 when Q = 0

#48 when Q = 1

<imm> For the four registers, immediate offset variant: is the post-index immediate offset, encoded in the Q field:

#32 when Q = 0

#64 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);
integer elements = datasize DIV esize;
```

```
integer rpt;    // number of iterations
integer selem;  // structure elements

case opcode of
    when '0000' rpt = 1; selem = 4;     // LD/ST4 (4 registers)
    when '0010' rpt = 4; selem = 1;     // LD/ST1 (4 registers)
    when '0100' rpt = 1; selem = 3;     // LD/ST3 (3 registers)
    when '0110' rpt = 3; selem = 1;     // LD/ST1 (3 registers)
    when '0111' rpt = 1; selem = 1;     // LD/ST1 (1 register)
    when '1000' rpt = 1; selem = 2;     // LD/ST2 (2 registers)
    when '1010' rpt = 2; selem = 1;     // LD/ST1 (2 registers)
    otherwise UnallocatedEncoding();

// .1D format only permitted with LD1 & ST1
if size:Q == '110' && selem != 1 then ReservedValue();
```

Operation for all classes

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(64) offs;
bits(datasize) rval;
integer e, r, s, tt;
constant integer ebytes = esize DIV 8;

if n == 31 then

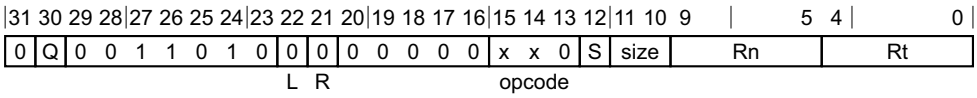
    if n == 31 then
        SP[] = address + offs;
    else
        X[n] = address + offs;
```

C7.3.276 ST1 (single structure)

Store single 1-element structure from one lane of one register

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



8-bit variant (opcode = 000)

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>]
```

16-bit variant (opcode = 010, size = x0)

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>]
```

32-bit variant (opcode = 100, size = 00)

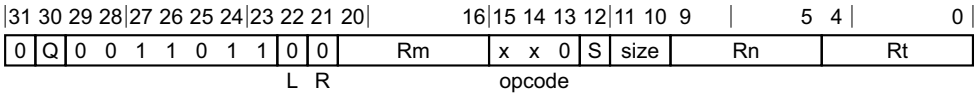
```
ST1 { <Vt>.S }[<index>], [<Xn|SP>]
```

64-bit variant (opcode = 100, S = 0, size = 01)

```
ST1 { <Vt>.D }[<index>], [<Xn|SP>]
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



8-bit, immediate offset variant (Rm = 11111, opcode = 000)

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>], #1
```

8-bit, register offset variant (Rm != 11111, opcode = 000)

```
ST1 { <Vt>.B }[<index>], [<Xn|SP>], <Xm>
```

16-bit, immediate offset variant (Rm = 11111, opcode = 010, size = x0)

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>], #2
```

16-bit, register offset variant (Rm != 11111, opcode = 010, size = x0)

```
ST1 { <Vt>.H }[<index>], [<Xn|SP>], <Xm>
```

32-bit, immediate offset variant (Rm = 11111, opcode = 100, size = 00)

```
ST1 { <Vt>.S }[<index>], [<Xn|SP>], #4
```

32-bit, register offset variant (Rm != 11111, opcode = 100, size = 00)

```
ST1 { <Vt>.S }[<index>], [<Xn|SP>], <Xm>
```

64-bit, immediate offset variant (Rm = 11111, opcode = 100, S = 0, size = 01)

```
ST1 { <Vt>.D }[<index>], [<Xn|SP>], #8
```

64-bit, register offset variant (Rm != 11111, opcode = 100, S = 0, size = 01)

```
ST1 { <Vt>.D }[<index>], [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.
<index>	For the 8-bit variant: is the element index, encoded in Q:S:size.
<index>	For the 16-bit variant: is the element index, encoded in Q:S:size<1>.
<index>	For the 32-bit variant: is the element index, encoded in Q:S.
<index>	For the 64-bit variant: is the element index, encoded in Q.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```

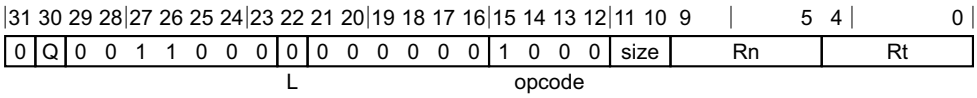
C7.3.277 ST2 (multiple structures)

Store multiple 2-element structures from two registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

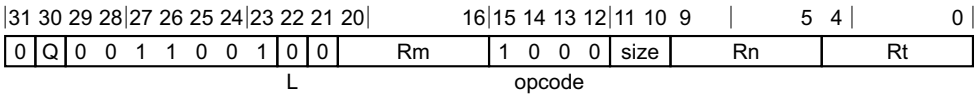


No offset variant

```
ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
ST2 { <Vt>.<T>, <Vt2>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt> Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vt2> Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

<Xn|SP> Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> Is the post-index immediate offset, encoded in the Q field:

#16 when Q = 0

#32 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = if Q == '1' then 128 else 64;
integer esize = 8 << UInt(size);

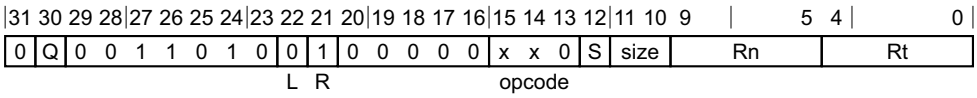
C7.3.278 ST2 (single structure)

Store single 2-element structure from one lane of two registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset



8-bit variant (opcode = 000)

```
ST2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>]
```

16-bit variant (opcode = 010, size = x0)

```
ST2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>]
```

32-bit variant (opcode = 100, size = 00)

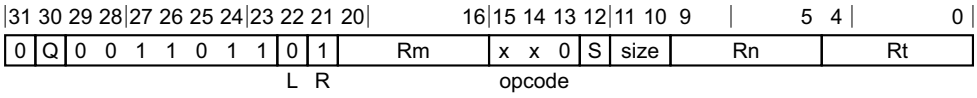
```
ST2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>]
```

64-bit variant (opcode = 100, S = 0, size = 01)

```
ST2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>]
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



8-bit, immediate offset variant (Rm = 11111, opcode = 000)

```
ST2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>], #2
```

8-bit, register offset variant (Rm != 11111, opcode = 000)

```
ST2 { <Vt>.B, <Vt2>.B }[<index>], [<Xn|SP>], <Xm>
```

16-bit, immediate offset variant (Rm = 11111, opcode = 010, size = x0)

```
ST2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>], #4
```

16-bit, register offset variant (Rm != 11111, opcode = 010, size = x0)

```
ST2 { <Vt>.H, <Vt2>.H }[<index>], [<Xn|SP>], <Xm>
```

32-bit, immediate offset variant (Rm = 11111, opcode = 100, size = 00)

```
ST2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>], #8
```

32-bit, register offset variant (Rm != 11111, opcode = 100, size = 00)

```
ST2 { <Vt>.S, <Vt2>.S }[<index>], [<Xn|SP>], <Xm>
```

64-bit, immediate offset variant (Rm = 11111, opcode = 100, S = 0, size = 01)

```
ST2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>], #16
```

64-bit, register offset variant (Rm != 11111, opcode = 100, S = 0, size = 01)

```
ST2 { <Vt>.D, <Vt2>.D }[<index>], [<Xn|SP>], <Xm>
```

```
integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.
<index>	For the 8-bit variant: is the element index, encoded in Q:S:size.
<index>	For the 16-bit variant: is the element index, encoded in Q:S:size<1>.
<index>	For the 32-bit variant: is the element index, encoded in Q:S.
<index>	For the 64-bit variant: is the element index, encoded in Q.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```

```

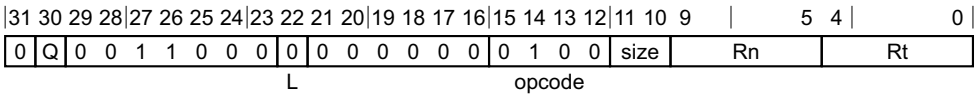
C7.3.279 ST3 (multiple structures)

Store multiple 3-element structures from three registers

It has encodings from 2 classes:*No offset* and *Post-index*

No offset

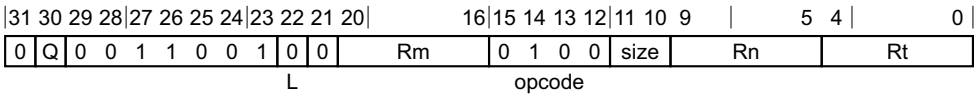


No offset variant

```
ST3 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>]

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = integer UNKNOWN;
boolean wback = FALSE;
```

Post-index



Immediate offset variant (Rm = 11111)

```
ST3 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <imm>
```

Register offset variant (Rm != 11111)

```
ST3 { <Vt>.<T>, <Vt2>.<T>, <Vt3>.<T> }, [<Xn|SP>], <Xm>

integer t = UInt(Rt);
integer n = UInt(Rn);
integer m = UInt(Rm);
boolean wback = TRUE;
```

Assembler symbols

`<Vt>` Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.

`<T>` Is an arrangement specifier, encoded in the size:Q field:

8B when size = `00`, Q = `0`

16B when size = `00`, Q = `1`

4H when size = `01`, Q = `0`

8H when size = `01`, Q = `1`

2S when size = `10`, Q = `0`

4S when size = `10`, Q = `1`

RESERVED when size = 11, Q = `0`

2D when size = 11, Q = `1`

`<Vt2>` Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.

`<Vt3>` Is the name of the third SIMD&FP register to be transferred, encoded as Rt plus 2 modulo 32.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

<imm> Is the post-index immediate offset, encoded in the Q field:

#24 when Q = 0

#48 when Q = 1

<Xm> Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

```
MemOp memop = if L == '1' then MemOp_LOAD else MemOp_STORE;

```

Assembler symbols

<Vt>	Is the name of the first or only SIMD&FP register to be transferred, encoded in the Rt field.
<Vt2>	Is the name of the second SIMD&FP register to be transferred, encoded as Rt plus 1 modulo 32.
<Vt3>	Is the name of the third SIMD&FP register to be transferred, encoded as Rt plus 2 modulo 32.
<Vt4>	Is the name of the fourth SIMD&FP register to be transferred, encoded as Rt plus 3 modulo 32.
<index>	For the 8-bit variant: is the element index, encoded in Q:S:size.
<index>	For the 16-bit variant: is the element index, encoded in Q:S:size<1>.
<index>	For the 32-bit variant: is the element index, encoded in Q:S.
<index>	For the 64-bit variant: is the element index, encoded in Q.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<Xm>	Is the 64-bit name of the general-purpose post-index register, excluding XZR, encoded in the Rm field.

Shared decode for all variants

Assembler symbols

`<Bt>` Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Dt>` Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Ht>` Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Qt>` Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<St>` Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.

`<Xn|SP>` Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.

`<R>` Is the index width specifier, encoded in the option field:

RESERVED when option = `00x`

W when option = `x10`

X when option = `x11`

RESERVED when option = `10x`

`<m>` Is the number [0-30] of the general-purpose index register or the name ZR (31), encoded in the Rm field.

`<extend>` Is the index extend/shift specifier, defaulting to LSL and encoded in the option field:

RESERVED when option = `00x`

UXTW when option = `010`

LSL when option = 011

RESERVED when option = 10x

SXTW when option = 110

SXTX when option = 111

<amount> For the 8-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

[absent] when S = 0

#0 when S = 1

<amount> For the 16-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#1 when S = 1

<amount> For the 32-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#2 when S = 1

<amount> For the 64-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#3 when S = 1

<amount> For the 128-bit variant: is the index shift amount, optional and defaulting to #0 when <extend> is not LSL, encoded in the S field:

#0 when S = 0

#4 when S = 1

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
integer m = UInt(Rm);
AccType acctype = AccType_VEC;
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
```

Operation

```
bits(64) offset = ExtendReg(m, extend_type, shift);
CheckFPAdvSIMDEnabled64();

bits(64) address;
bits(datasize) data;

if n == 31 then
    CheckSPAlignment();

```

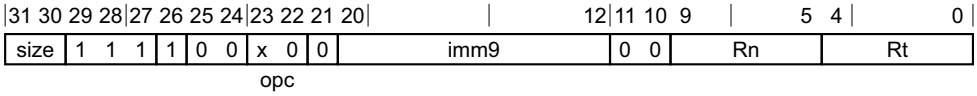
C7.3.287 STUR (SIMD&FP)

Store SIMD&FP register (unscaled offset)



8-bit variant (size = 00, opc = 00)

```
STUR <Bt>, [<Xn|SP>{, #<simm>}]
```

16-bit variant (size = 01, opc = 00)

```
STUR <Ht>, [<Xn|SP>{, #<simm>}]
```

32-bit variant (size = 10, opc = 00)

```
STUR <St>, [<Xn|SP>{, #<simm>}]
```

64-bit variant (size = 11, opc = 00)

```
STUR <Dt>, [<Xn|SP>{, #<simm>}]
```

128-bit variant (size = 00, opc = 10)

```
STUR <Qt>, [<Xn|SP>{, #<simm>}]
```

```
boolean wback = FALSE;
boolean postindex = FALSE;
integer scale = UInt(opc<1>:size);
if scale > 4 then UnallocatedEncoding();
bits(64) offset = SignExtend(imm9, 64);
```

Assembler symbols

<Bt>	Is the 8-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.
<Dt>	Is the 64-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.
<Ht>	Is the 16-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.
<Qt>	Is the 128-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.
<St>	Is the 32-bit name of the SIMD&FP register to be transferred, encoded in the Rt field.
<Xn|SP>	Is the 64-bit name of the general-purpose base register or stack pointer, encoded in the Rn field.
<simm>	Is the optional signed immediate byte offset, in the range -256 to 255, defaulting to 0 and encoded in the imm9 field.

Shared decode for all variants

```
integer n = UInt(Rn);
integer t = UInt(Rt);
AccType acctype = AccType_VEC;
MemOp memop = if opc<0> == '1' then MemOp_LOAD else MemOp_STORE;
integer datasize = 8 << scale;
```

Operation

```
CheckFPAdvSIMDEnabled64();

bits(64) address;
```

```
bits(datasize) data;

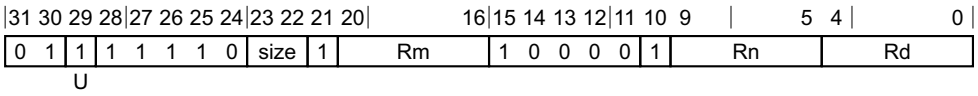
```

C7.3.288 SUB (vector)

Subtract (vector)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar

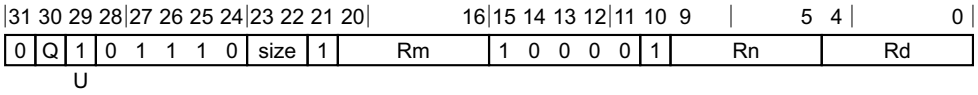


Scalar variant

```
SUB <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size != '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;
boolean sub_op = (U == '1');
```

Vector



Vector variant

```
SUB <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean sub_op = (U == '1');
```

Assembler symbols

<V>	Is a width specifier, encoded in the size field: **RESERVED** when size = 0x **RESERVED** when size = 10 **D** when size = 11
<d>	Is the number of the SIMD&FP destination register, in the Rd field.
<n>	Is the number of the first SIMD&FP source register, encoded in the Rn field.
<m>	Is the number of the second SIMD&FP source register, encoded in the Rm field.
<Vd>	Is the name of the SIMD&FP destination register, encoded in the Rd field.
<T>	Is an arrangement specifier, encoded in the size:Q field: **8B** when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation for all classes

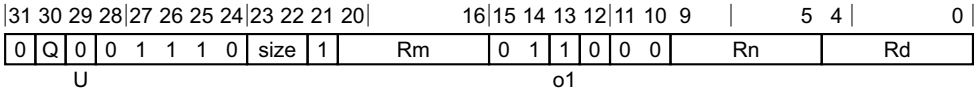
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;
bits(esize) element1;
bits(esize) element2;

for e = 0 to elements-1
    element1 = Elem[operand1, e, esize];
    element2 = Elem[operand2, e, esize];
    if sub_op then
        Elem[result, e, esize] = element1 - element2;
    else
        Elem[result, e, esize] = element1 + element2;

V[d] = result;
```

C7.3.289 SUBHN, SUBHN2

Subtract returning high narrow



Three registers, not all the same type variant

```
SUBHN{2} <Vd>.<Tb>, <Vn>.<Ta>, <Vm>.<Ta>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

boolean sub_op = (o1 == '1');
boolean round = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(2*datasize) operand1 = V[n];
bits(2*datasize) operand2 = V[m];
bits(datasize)   result;
integer round_const = if round then 1 << (esize - 1) else 0;
bits(2*esize) element1;
bits(2*esize) element2;
bits(2*esize) sum;

for e = 0 to elements-1
    element1 = Elem[operand1, e, 2*esize];
    element2 = Elem[operand2, e, 2*esize];
    if sub_op then
        sum = element1 - element2;
    else
        sum = element1 + element2;
    sum = sum + round_const;
    Elem[result, e, esize] = sum<2*esize-1:esize>;

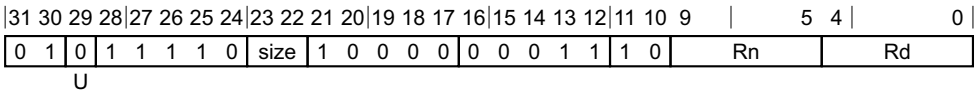
Vpart[d, part] = result;
```

C7.3.290 SUQADD

Signed saturating accumulate of unsigned value

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

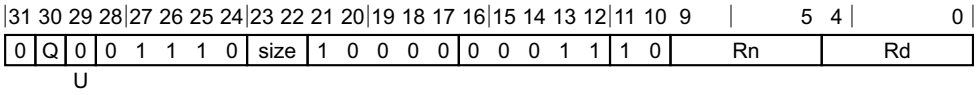
```
SUQADD <V><d>, <V><n>

integer d = UInt(Rd);
integer n = UInt(Rn);

integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

boolean unsigned = (U == '1');
```

Vector



Vector variant

```
SUQADD <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

- **B** when size = 00
- **H** when size = 01
- **S** when size = 10
- **D** when size = 11

<d> Is the number of the SIMD&FP destination register, encoded in the Rd field.

<n> Is the number of the SIMD&FP source register, encoded in the Rn field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;

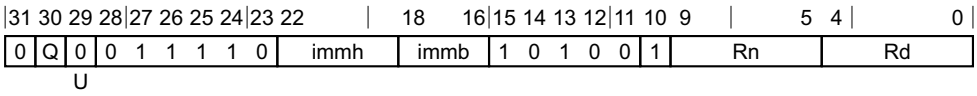
bits(datasize) operand2 = V[d];
integer op1;
integer op2;
boolean sat;

for e = 0 to elements-1
    op1 = Int(Elem[operand, e, esize], !unsigned);
    op2 = Int(Elem[operand2, e, esize], unsigned);
    (Elem[result, e, esize], sat) = SatQ(op1 + op2, esize, unsigned);
    if sat then FPSR.QC = '1';
V[d] = result;
```

C7.3.291 SXTL

Signed extend long

This instruction is an alias of the SSHLL, SSHLL2 instruction.



Vector variant

`SXTL{2} <Vd>.<Ta>, <Vn>.<Tb>`

is equivalent to

`SSHLL{2} <Vd>.<Ta>, <Vn>.<Tb>, #0`

and is the preferred disassembly when `BitCount(immh) == 1 && immb == '000'`.

Assembler symbols

`2` Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = `0`

[present] when Q = `1`

`<Vd>` Is the name of the SIMD&FP destination register, encoded in the Rd field.

`<Ta>` Is an arrangement specifier, encoded in the immh field:

See Advanced SIMD modified immediate. when immh = `0000`

8H when immh = `0001`

4S when immh = `001x`

2D when immh = `01xx`

RESERVED when immh = `1xxx`

`<Vn>` Is the name of the SIMD&FP source register, encoded in the Rn field.

`<Tb>` Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = `0000`, Q = `x`

8B when immh = `0001`, Q = `0`

16B when immh = `0001`, Q = `1`

4H when immh = `001x`, Q = `0`

8H when immh = `001x`, Q = `1`

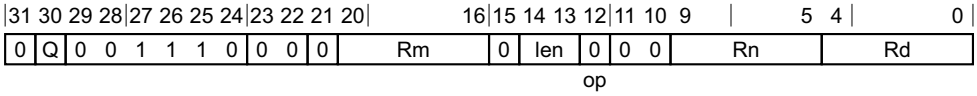
2S when immh = `01xx`, Q = `0`

4S when immh = `01xx`, Q = `1`

RESERVED when immh = `1xxx`, Q = `x`

C7.3.292 TBL

Table vector lookup



Two register table variant (len = 01)

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>
```

Three register table variant (len = 10)

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>
```

Four register table variant (len = 11)

```
TBL <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>
```

Single register table variant (len = 00)

```
TBL <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the Rn field.

<Vn> For the single register table variant: is the name of the SIMD&FP table register, encoded in the Rn field.

<Vn+1> Is the name of the second SIMD&FP table register, encoded as Rn plus 1 modulo 32.

<Vn+2> Is the name of the third SIMD&FP table register, encoded as Rn plus 2 modulo 32.

<Vn+3> Is the name of the fourth SIMD&FP table register, encoded as Rn plus 3 modulo 32.

<Vm> Is the name of the SIMD&FP index register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;
```

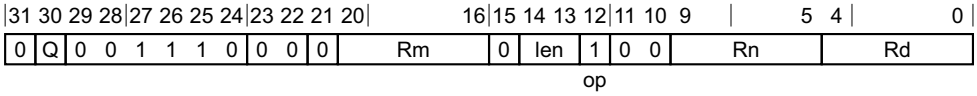
```
// Create table from registers
for i = 0 to regs - 1
    table<128*i+127:128*i> = V[n];
    n = (n + 1) MOD 32;

result = if is_tbl then Zeros() else V[d];
for i = 0 to elements - 1
    index = UInt(Elem[indices, i, 8]);
    if index < 16 * regs then
        Elem[result, i, 8] = Elem[table, index, 8];

V[d] = result;
```

C7.3.293 TBX

Table vector lookup extension



Two register table variant (len = 01)

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B }, <Vm>.<Ta>
```

Three register table variant (len = 10)

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B }, <Vm>.<Ta>
```

Four register table variant (len = 11)

```
TBX <Vd>.<Ta>, { <Vn>.16B, <Vn+1>.16B, <Vn+2>.16B, <Vn+3>.16B }, <Vm>.<Ta>
```

Single register table variant (len = 00)

```
TBX <Vd>.<Ta>, { <Vn>.16B }, <Vm>.<Ta>
```

```
integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV 8;
integer regs = UInt(len) + 1;
boolean is_tbl = (op == '0');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the Q field:

8B when Q = 0

16B when Q = 1

<Vn> For the four register table, three register table and two register table variant: is the name of the first SIMD&FP table register, encoded in the Rn field.

<Vn> For the single register table variant: is the name of the SIMD&FP table register, encoded in the Rn field.

<Vn+1> Is the name of the second SIMD&FP table register, encoded as Rn plus 1 modulo 32.

<Vn+2> Is the name of the third SIMD&FP table register, encoded as Rn plus 2 modulo 32.

<Vn+3> Is the name of the fourth SIMD&FP table register, encoded as Rn plus 3 modulo 32.

<Vm> Is the name of the SIMD&FP index register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize) indices = V[m];
bits(128*regs) table = Zeros();
bits(datasize) result;
integer index;
integer i;
```

```
// Create table from registers
for i = 0 to regs - 1

```

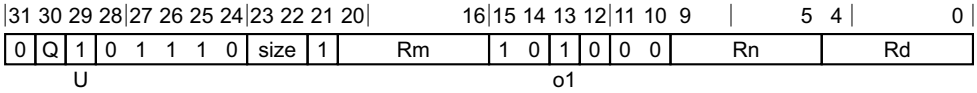
C7.3.320 UMLSL, UMLSL2 (vector)

Unsigned multiply-subtract long (vector)



Three registers, not all the same type variant

```
UMLSL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Tb>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);

if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean sub_op = (o1 == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> Is an arrangement specifier, encoded in the size field:

8H when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(datasize)   operand2 = Vpart[m, part];
bits(2*datasize) operand3 = V[d];
bits(2*datasize) result;
integer element1;
integer element2;
bits(2*esize) product;
bits(2*esize) accum;

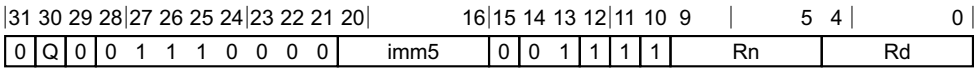
for e = 0 to elements-1
    element1 = Int(Elem[operand1, e, esize], unsigned);
    element2 = Int(Elem[operand2, e, esize], unsigned);
    product = (element1 * element2)<2*esize-1:0>;
    if sub_op then
        accum = Elem[operand3, e, 2*esize] - product;
    else
        accum = Elem[operand3, e, 2*esize] + product;
    Elem[result, e, 2*esize] = accum;

V[d] = result;
```

C7.3.321 UMOV

Unsigned move vector element to general-purpose register

This instruction is used by the alias MOV (to general). The alias is always the preferred disassembly.



32-bit variant (Q = 0)

```
UMOV <Wd>, <Vn>.<Ts>[<index>]
```

64-bit variant (Q = 1)

```
UMOV <Xd>, <Vn>.<Ts>[<index>]

integer d = UInt(Rd);
integer n = UInt(Rn);

integer size;
case Q:imm5 of
    when '0xxxx1' size = 0;     // UMOV Wd, Vn.B
    when '0xxx10' size = 1;     // UMOV Wd, Vn.H
    when '0xx100' size = 2;     // UMOV Wd, Vn.S
    when '1x1000' size = 3;     // UMOV Xd, Vn.D
    otherwise     UnallocatedEncoding();

integer idxdsize = if imm5<4> == '1' then 128 else 64;
integer index = UInt(imm5<4:size+1>);
integer esize = 8 << size;
integer datasize = if Q == '1' then 64 else 32;
```

Assembler symbols

<Wd> Is the 32-bit name of the general-purpose destination register, encoded in the Rd field.

<Xd> Is the 64-bit name of the general-purpose destination register, encoded in the Rd field.

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Ts> For the 32-bit variant: is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = xx000

B when imm5 = xxxx1

H when imm5 = xxx10

S when imm5 = xx100

<Ts> For the 64-bit variant: is an element size specifier, encoded in the imm5 field:

RESERVED when imm5 = x0000

RESERVED when imm5 = xxxx1

RESERVED when imm5 = xxx10

RESERVED when imm5 = xx100

D when imm5 = x1000

<index> For the 32-bit variant: is the element index encoded in the imm5 field:

RESERVED when imm5 = xx000

imm5<4:1> when imm5 = xxxx1

imm5<4:2> when imm5 = xxx10

imm5<4:3> when imm5 = xx100

<index> For the 64-bit variant: is the element index encoded in imm5<4>.

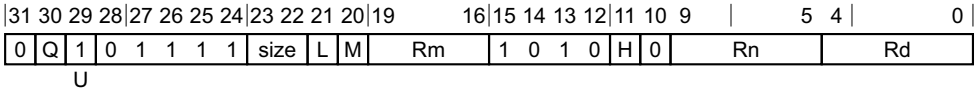
Operation

```
CheckFPAdvSIMDEnabled64();
bits(idxdsize) operand = V[n];

X[d] = ZeroExtend(Elem[operand, index, esize], datasize);
```

C7.3.322 UMULL, UMULL2 (by element)

Unsigned multiply long (vector, by element)



Vector variant

```
UMULL{2} <Vd>.<Ta>, <Vn>.<Tb>, <Vm>.<Ts>[<index>]

integer idxdsize = if H == '1' then 128 else 64;
integer index;
bit Rmhi;
case size of
    when '01' index = UInt(H:L:M); Rmhi = '0';
    when '10' index = UInt(H:L);   Rmhi = M;
    otherwise UnallocatedEncoding();

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rmhi:Rm);

integer esize = 8 << UInt(size);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
```

Assembler symbols

2 — Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> — Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Ta> — Is an arrangement specifier, encoded in the size field:

RESERVED when size = 00

4S when size = 01

2D when size = 10

RESERVED when size = 11

<Vn> — Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Tb> — Is an arrangement specifier, encoded in the size:Q field:

RESERVED when size = 00, Q = x

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = x

<Vm> Is the name of the second SIMD&FP source register, encoded in the size:M:Rm field:

RESERVED when size = 00

0:Rm when size = 01

M:Rm when size = 10

RESERVED when size = 11

Restricted to V0-V15 when element size <Ts> is H.

<Ts> Is an element size specifier, encoded in the size field:

RESERVED when size = 00

H when size = 01

S when size = 10

RESERVED when size = 11

<index> Is the element index encoded in the size:L:H:M field:

RESERVED when size = 00

H:L:M when size = 01

H:L when size = 10

RESERVED when size = 11

Operation

```
CheckFPAdvSIMDEnabled64();
bits(datasize)   operand1 = Vpart[n, part];
bits(idxdsize)   operand2 = V[m];
bits(2*datasize) result;
integer element1;

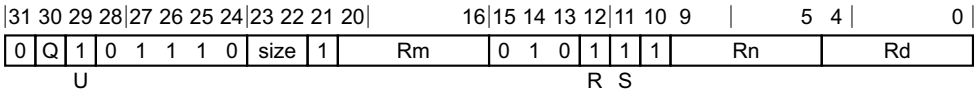
if S == '0' && size != '11' then ReservedValue();
```

Vector



Vector variant

```
UQSHL <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size:Q == '110' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
boolean unsigned = (U == '1');
boolean rounding = (R == '1');
boolean saturating = (S == '1');
```

Assembler symbols

<V> Is a width specifier, encoded in the size field:

- **B** when size = 00
- **H** when size = 01
- **S** when size = 10
- **D** when size = 11

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<m> Is the number of the second SIMD&FP source register, encoded in the Rm field.

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1

2S when size = 10, Q = 0

4S when size = 10, Q = 1

RESERVED when size = 11, Q = 0

2D when size = 11, Q = 1

<Vn> Is the name of the first SIMD&FP source register, encoded in the Rn field.

<Vm> Is the name of the second SIMD&FP source register, encoded in the Rm field.

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand1 = V[n];
bits(datasize) operand2 = V[m];
bits(datasize) result;

integer round_const = 0;
integer shift;
integer element;
boolean sat;

for e = 0 to elements-1
    shift = SInt(Elem[operand2, e, esize]<7:0>);
    if rounding then
        round_const = 1 << (-shift - 1); // 0 for left shift, 2^(n-1) for right shift
    element = (Int(Elem[operand1, e, esize], unsigned) + round_const) << shift;
    if saturating then
        (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
        if sat then FPSR.QC = '1';
    else
        Elem[result, e, esize] = element<esize-1:0>;

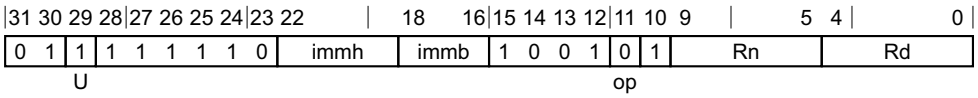
V[d] = result;
```

C7.3.329 UQSHRN

Unsigned saturating shift right narrow (immediate)

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

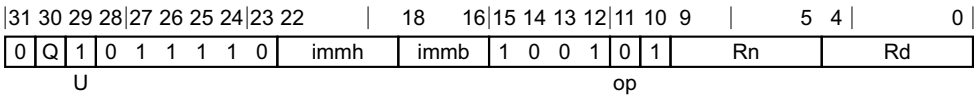
```
UQSHRN <Vb><d>, <Va><n>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then ReservedValue();
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = esize;
integer elements = 1;
integer part = 0;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

Vector



Vector variant

```
UQSHRN{2} <Vd>.<Tb>, <Vn>.<Ta>, #<shift>

integer d = UInt(Rd);
integer n = UInt(Rn);

if immh == '0000' then SEE(Advanced SIMD modified immediate);
if immh<3> == '1' then ReservedValue();
integer esize = 8 << HighestSetBit(immh);
integer datasize = 64;
integer part = UInt(Q);
integer elements = datasize DIV esize;

integer shift = (2 * esize) - UInt(immh:immb);
boolean round = (op == '1');
boolean unsigned = (U == '1');
```

Assembler symbols

2 Is the second and upper half specifier. If present it causes the operation to be performed on the upper 64 bits of the registers holding the narrower elements, and is encoded in the Q field:

[absent] when Q = 0

[present] when Q = 1

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<Tb> Is an arrangement specifier, encoded in the immh:Q field:

See Advanced SIMD modified immediate. when immh = 0000, Q = x

8B when immh = 0001, Q = 0

16B when immh = 0001, Q = 1

4H when immh = 001x, Q = 0

8H when immh = 001x, Q = 1

2S when immh = 01xx, Q = 0

4S when immh = 01xx, Q = 1

RESERVED when immh = 1xxx, Q = x

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

<Ta> Is an arrangement specifier, encoded in the immh field:

See Advanced SIMD modified immediate. when immh = 0000

8H when immh = 0001

4S when immh = 001x

2D when immh = 01xx

RESERVED when immh = 1xxx

<Vb> Is the destination width specifier, encoded in the immh field:

RESERVED when immh = 0000

B when immh = 0001

H when immh = 001x

S when immh = 01xx

RESERVED when immh = 1xxx

<d> Is the number of the SIMD&FP destination register, in the Rd field.

<Va> Is the source width specifier, encoded in the immh field:

RESERVED when immh = 0000

H when immh = 0001

S when immh = 001x

D when immh = 01xx

RESERVED when immh = 1xxx

<n> Is the number of the first SIMD&FP source register, encoded in the Rn field.

<shift> For the scalar variant: is the right shift amount, in the range 1 to the destination operand width in bits, encoded in the immh:immb field:

RESERVED when immh = 0000

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

RESERVED when immh = 1xxx

<shift> For the vector variant: is the right shift amount, in the range 1 to the destination element width in bits, encoded in the immh:immb field:

See Advanced SIMD modified immediate. when immh = 0000

(16-UInt(immh:immb)) when immh = 0001

(32-UInt(immh:immb)) when immh = 001x

(64-UInt(immh:immb)) when immh = 01xx

RESERVED when immh = 1xxx

Operation for all classes

```
CheckFPAdvSIMDEnabled64();
bits(datasize*2) operand = V[n];
bits(datasize) result;
integer round_const = if round then (1 << (shift - 1)) else 0;
integer element;
boolean sat;

for e = 0 to elements-1
    element = (Int(Elem[operand, e, 2*esize], unsigned) + round_const) >> shift;
    (Elem[result, e, esize], sat) = SatQ(element, esize, unsigned);
    if sat then FPSR.QC = '1';

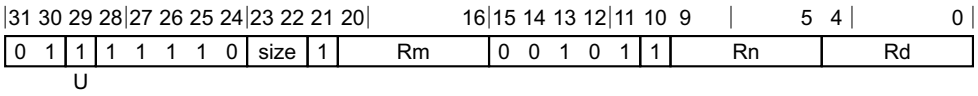
Vpart[d, part] = result;
```

C7.3.330 UQSUB

Unsigned saturating subtract

It has encodings from 2 classes:*Scalar* and *Vector*

Scalar



Scalar variant

```
UQSUB <V><d>, <V><n>, <V><m>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
integer esize = 8 << UInt(size);
integer datasize = esize;
integer elements = 1;

    if sat then FPSR.QC = '1';

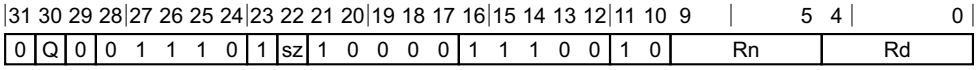
Vpart[d, part] = result;
```

C7.3.332 URECPE

Unsigned reciprocal estimate



Vector variant

```
URECPE <Vd>.<T>, <Vn>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);

if sz == '1' then ReservedValue();
integer esize = 32;
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the sz:Q field:

2S when sz = 0, Q = 0

4S when sz = 0, Q = 1

RESERVED when sz = 1, Q = x

<Vn> Is the name of the SIMD&FP source register, encoded in the Rn field.

Operation

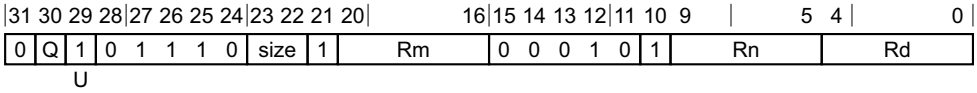
```
CheckFPAdvSIMDEnabled64();
bits(datasize) operand = V[n];
bits(datasize) result;
bits(32) element;

for e = 0 to elements-1
    element = Elem[operand, e, 32];
    Elem[result, e, 32] = UnsignedRecipEstimate(element);

V[d] = result;
```

C7.3.333 URHADD

Unsigned rounding halving add



Three registers of the same type variant

```
URHADD <Vd>.<T>, <Vn>.<T>, <Vm>.<T>

integer d = UInt(Rd);
integer n = UInt(Rn);
integer m = UInt(Rm);
if size == '11' then ReservedValue();
integer esize = 8 << UInt(size);
integer datasize = if Q == '1' then 128 else 64;
integer elements = datasize DIV esize;

boolean unsigned = (U == '1');
```

Assembler symbols

<Vd> Is the name of the SIMD&FP destination register, encoded in the Rd field.

<T> Is an arrangement specifier, encoded in the size:Q field:

8B when size = 00, Q = 0

16B when size = 00, Q = 1

4H when size = 01, Q = 0

8H when size = 01, Q = 1
