# PetaLinux Tools Documentation

---

## Introduction

PetaLinux is an Embedded Linux System Development Kit specifically targeting FPGA-based System-on-Chip designs. This guide helps the reader to familiarize with the tool enabling overall usage of PetaLinux.

**Note:** The reader of this document is assumed to have basic Linux knowledge, such as how to run Linux commands. The reader should also be aware of OS and Host system features such as OS bit version, Linux Distribution and Security Privileges.

The new PetaLinux tool contains the following:

1. Yocto Extensible SDK

[Table 1-1](#) details the 4 Extensible SDK's installed.

*Table 1-1: Extensible SDK's*

Path	Architecture
\$PETALINUX/components/yocto/source/aarch64	for Zynq® Ultrascale+™ MPSoC
\$PETALINUX/components/yocto/source/arm	for Zynq
\$PETALINUX/components/yocto/source/microblaze_full	for MicroBlaze™ full designs
\$PETALINUX/components/yocto/source/microblaze_lite	for MicroBlaze lite designs

The e-SDK consists of:

- a. Layers - This contains all the layers for an architecture. The e-SDK had poky, meta-oe and other popular layers.

**Table 1-2: Layers from Xilinx**

Layer	Recipes
meta-xilinx	Contains recipes of linux kernel, uboot and ATF
meta-xilinx-tools	Contains recipes of all embeddedSW apps: fsbl, pmufw, fsboot, device-tree
meta-petalinux	Contains distro recipes and package groups petalinux-minimal --> minimal feature set petalinux-image ---> Full feature set

For example, for Zynq Ultrascale+ MPSoC:

```
$PETALINUX/components/yocto/source/aarch64/layers
```

- b. sstate-cache - By design, the OpenEmbedded build system builds everything from scratch unless BitBake can determine that parts do not need to be rebuilt. Fundamentally, building from scratch is attractive as it means all parts are built fresh and there is no possibility of stale data causing problems.

The Yocto Project implements shared state code that supports incremental builds. It stores all task intermediate build artifacts and reuses them if there is no change in input tasks, hence reduces the build time

For example: The sstate-cache of Zynq Ultrascale+ MPSoC is at:

```
$PETALINUX/components/yocto/source/aarch64/sstate-cache
```

- c. sysroot - This contains sysroot for host and the target

For example: The sysroot of Zynq Ultrascale+ MPSoC is at:

```
$PETALINUX/components/yocto/source/aarch64/sysroot
```

## 2. Minimal downloads

BitBake checks pre-mirrors before looking upstream for any source files. Pre-mirrors are appropriate when you have a shared directory that is not a directory defined by the DL\_DIR variable. A Pre-mirror points to a shared directory that is in tool. All projects of the tool use these pre-mirrors and fetch the source code from them.

The pre-mirror in tool points to: `$PETALINUX/components/yocto/downloads`.

The downloads directory will have tar balls of source code for linux kernel, uboot and other minimal utilities.

3. XSCT and tool chains

The PetaLinux tool uses XSCT underneath for all embeddedSW apps. It also contains tool chains of all architectures.

4. PetaLinux Commands

This contains all the petalinux commands which you require.

## Installation Requirements

The PetaLinux Tools Installation requirements are:

- Minimum workstation requirements:
  - 4 GB RAM (recommended minimum for Xilinx tools)
  - Pentium 4 2GHz CPU clock or equivalent (minimum of 4 cores)
  - 100 GB free HDD space
  - Supported OS:
    - RHEL 6.6/6.7/7.1/7.2 (64-bit)
    - CentOS 7.1 (64-bit)
    - SUSE Enterprise 12.0 (64-bit)
    - Ubuntu 16.04 (64 bit)
- You need to have root access to perform some operations.
- PetaLinux requires a number of standard development tools and libraries to be installed on your Linux host workstation. Install the libraries and tools listed in the following table on your host Linux. All of the listed Linux Workstation Environments below have the 32-bit libraries needed by the PetaLinux tool. If any addition tool chains are packages needing 32-bit libs on host are needed, install the same before issuing petalinux-build. [Table 1-3](#) below describes the required packages, and how to install them on different Linux workstation environments.

Table 1-3: Packages and Linux Workstation Environments

Tool / Library	CentOS7.1	RHEL6.6	RHEL6.7	RHEL7.1	RHEL7.2	SUSE 12.0	Ubuntu 16.04

automake	automake	automake	automake	automake	automake	automake	-

**CAUTION!** Consult your system administrator if you are not sure about the correct procedures for host system package management.

**IMPORTANT:** PetaLinux tools require your host system `/bin/sh` is `bash`. If you are using Ubuntu distribution and your `/bin/sh` is `dash`, you can consult your system administrator to change your default with `sudo dpkg-reconfigure dash` command.

**IMPORTANT:** PetaLinux v2016.4 works with Vivado 2016.4.

## Installation Steps

### Prerequisites

The prerequisites to install the PetaLinux tools are:

- PetaLinux Tools Installation Requirements is completed. Refer to the [Installation Requirements](#) section.
- PetaLinux release package is downloaded. You can download PetaLinux installer from [PetaLinux Downloads](#).

## Run PetaLinux Tools Installer

PetaLinux Tools installation is very straight-forward. Without any options, PetaLinux Tools will be installed into the current working directory. Alternatively, an installation path may be specified.

For example: To install PetaLinux Tools under `"/opt/pkg/petalinux"`:

```
$ mkdir -p /opt/pkg/petalinux
$ ./petalinux-v2016.4-final-installer.run /opt/pkg/petalinux
```

This will install the PetaLinux Tools into `"/opt/pkg/petalinux"` directory.

---

**IMPORTANT:** *Once installed you cannot move or copy the installed directory. In the above example you cannot move or copy `/opt/pkg/petalinux`.*

---

Reading and agreeing to the PetaLinux End User License Agreement (EULA) is a required and integral part of the PetaLinux Tools installation process. Users can read the license agreement prior to running the installation. If you wish to keep the license for your records, the licenses are available in plain ASCII text in the following files:

- `$PETALINUX/etc/license/petalinux-license.txt`. EULA specifies in detail the rights and restrictions that apply to the PetaLinux.
- `$PETALINUX/etc/license/Third_Party_Software_End_User_License_Agreement.txt`. The third party license agreement specifies in details the licenses of the distributable and non-distributable components in PetaLinux tools.

**Note:** PetaLinux tools do not require a license to install or run.

By default, the webtalk option is enabled to send tools usage statistics back to Xilinx. You can turn off the webtalk feature by running the `petalinux-util --webtalk` command:

---

**IMPORTANT:** *Before running the PetaLinux command, you will need to source PetaLinux settings first. Refer to section [PetaLinux Working Environment Setup](#).*

---

```
$ petalinux-util --webtalk off
```

## Troubleshooting

This section describes some common issues you may experience while installing the PetaLinux Tools. If the PetaLinux Tools installation fails, the file "\$PETALINUX/post-install.log" will be generated in your PetaLinux installation directory.

Table 1-4: PetaLinux Installation Troubleshooting

Problem / Error Message	Description and Solution
<p>WARNING: You have less than 1 Gbyte free space on the installation drive</p>	<p><b>Problem Description:</b> This warning message indicates that installation drive is almost full. You may not have enough free space to develop your hardware project and/or software project after the installation.</p> <p><b>Solution:</b></p> <ul style="list-style-type: none"> <li>• Clean up the installation drive to clear some more free space.</li> </ul> <p>Alternatively,</p> <ul style="list-style-type: none"> <li>• Move PetaLinux installation to another hard disk drive.</li> </ul>
<p>WARNING: No tftp server found</p>	<p><b>Problem Description:</b> This warning message indicates that you do not have a TFTP service running on your workstation. Without a TFTP service, you cannot download Linux system images to your target system using u-boot's network/TFTP capabilities. This warning can be ignored for other boot modes.</p> <p><b>Solution:</b> Enable the TFTP service on your workstation. If you are unsure how to enable this service, contact your system administrator.</p>
<p>ERROR: GCC is not installed - unable to continue. Please install and retry</p>	<p><b>Problem Description:</b> This error message indicates that you do not have gcc installed on your workstation.</p> <p><b>Solution:</b> Install gcc using your Linux work-station's package management system. If you are unsure how to do this, contact your system administrator.</p>

Table 1-4: PetaLinux Installation Troubleshooting (Cont'd)

Problem / Error Message	Description and Solution
<p>ERROR: You are missing the following system tools required by PetaLinux: missing-tools-list or ERROR: You are missing these development libraries required by PetaLinux: missing-library-list</p>	<p><b>Problem Description:</b> This error message indicates that you do not have the required tools or libraries listed in the "missing-tools-list" or "missing-library-list".</p> <p><b>Solution:</b> Install the packages of the missing tools. Refer to section <a href="#">Installation Requirements</a> for details.</p>
<p>Failed to open PetaLinux lib.</p>	<p><b>Problem Description:</b> This error message indicates that a PetaLinux library failed to load. The possible reasons are:</p> <ul style="list-style-type: none"> <li>• The PetaLinux "settings.sh" has not been loaded.</li> <li>• The Linux Kernel you are running has SELinux configured. This can cause issues with regards to security context and loading libraries.</li> </ul> <p><b>Solution:</b></p> <ol style="list-style-type: none"> <li>1. Source the "settings.sh" script from the top-level PetaLinux directory. Refer to section <a href="#">PetaLinux Working Environment Setup</a> for more details.</li> <li>2. If you have SELinux enabled, determine if SELinux is in 'enforcing mode'.</li> </ol> <p>If SELinux is configured in 'enforcing mode', either reconfigure SELinux to 'permissive mode' (refer to SELinux manual), or change the security context of the libraries to allow access (see below for details).</p> <pre>\$ cd \$PETALINUX/tools/common/petalinux/lib \$ chcon -R -t textrel_shlib_t lib</pre>

## PetaLinux Working Environment Setup

After the installation, the remaining setup is completed automatically by sourcing the provided "settings" scripts.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- PetaLinux Tools Installation is completed. Refer to section [Installation Steps](#).
- "/bin/sh" is bash.

## Steps to Setup PetaLinux Working Environment

1. Source the appropriate settings script:

- For Bash as user login shell:

```
$ source <path-to-installed-PetaLinux>/settings.sh
```

- For C shell as user login shell:

```
$ source <path-to-installed-PetaLinux>/settings.csh
```

Below is an example of the output when sourcing the setup script for the first time:

```
PetaLinux environment set to 'opt/pkg/petalinux'
INFO: Checking free disk space
INFO: Checking installed tools
INFO: Checking installed development libraries
INFO: Checking network and other services
WARNING: No tftp server found - please refer to "PetaLinux SDK Installation Guide"
for its impact and solution
```

2. Verify that the working environment has been set:

```
$ echo $PETALINUX
/opt/pkg/petalinux
```

Environment variable "\$PETALINUX" should point to the installed PetaLinux path. Your output may be different from this example, based on the PetaLinux installation path.

## Troubleshooting

This section describes some common issues you may experience while setting up PetaLinux Working Environment.

Table 1-5: PetaLinux Working Environment Troubleshooting

Problem / Error Message	Description and Solution
WARNING: /bin/sh is not bash	<p><b>Problem Description:</b> This warning message indicates that your default shell is linked to dash.</p> <p><b>Solution:</b> See <a href="#">Ubuntu Forum</a> and follow the steps.</p>

## PetaLinux BSP Installation

PetaLinux reference board support packages (BSPs) are reference designs for you to start working with and customize for your own projects. These are provided in the form of installable BSP files, and includes all necessary design and configuration files, pre-built and tested hardware and software images, ready for downloading on your board or for booting in the QEMU system emulation environment.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- PetaLinux BSP is downloaded. You can download PetaLinux BSP from [PetaLinux Downloads](#).
- PetaLinux Working Environment Setup is completed. Refer to section [PetaLinux Working Environment Setup](#).

### PetaLinux BSP Installation Steps

Follow the below steps to install a BSP:

1. Change to the directory under which you want PetaLinux projects to be created. For example, if you want to create projects under `/home/user`:

```
$ cd/home/user
```

2. Run `petalinux-create` command on the command console:

```
petalinux-create -t project -s <path-to-bsp>
```

The board being referenced is based on the BSP installed. You will see the output, similar to the below output:

```
INFO: Create project:
INFO: Projects:
INFO:   * xilinx-zcu102-v2016.4-final.bsp
INFO: has been successfully installed to /home/user/
INFO: New project successfully created in /home/user/
```

If the specified location is on NFS, it changes the `TMPDIR` to `/tmp/<projname_timestamp>`. If `/tmp/<projname_timestamp>` is also on NFS, it will throw an error.

In the above example, upon execution of `petalinux-create` command, the projects extracted from BSP and being installed are listed on the display console. If you run `ls` from `/home/user`, you will see the installed projects.

## Troubleshooting

This section describes some common issues you may experience while installing PetaLinux BSP.

Table 1-6: PetaLinux BSP Installation Troubleshooting

Problem / Error Message	Description and Solution
petalinux-create: command not found	<p><b>Problem Description:</b> This message indicates that it is unable to find "petalinux-create" command, hence it can't proceed with BSP installation.</p> <p><b>Solution:</b> You have to setup your environment for PetaLinux Tools. Refer to section <a href="#">PetaLinux Working Environment Setup</a> to set it up.</p>

## BSP Naming

Unlike earlier, there are multiple revisions of silicon and board that are being shipped. [Table 1-7](#) lists the supported BSPs that can be downloaded, for Zynq UltraScale family.

Table 1-7: BSP Naming

Platform	Silicon Version	Board Version	PetaLinux BSP Name
ZCU102	1.0 Silicon (DA7)	Rev-B	xilinx-zcu102-v2016.4-final.bsp
		Rev-C	
		Rev-D	
	3.0 Silicon (DA7-ES2)	Rev-1.0	xilinx-zcu102-zu9-es2-rev1.0-v2016.4-final.bsp

[Click here](#) to download the BSPs.

## Create Hardware Platform with Vivado

This section describes how to configure a hardware platform ready for PetaLinux Project.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- Vivado® Design Suite is installed. You can download Vivado Design Suite from [Vivado Design Tool Downloads](#).
- You have setup Vivado Tools Working Environment. If you have not, source the appropriate settings scripts as follows.

```
$ source <path-to-installed-Xilinx-Vivado>/settings64.sh
```

- You know how to use Xilinx Vivado and SDK tools.

## Configure a Hardware Platform for Linux

You can create your own hardware platform with Vivado. Regardless of how the hardware platform is created and configured, there are a small number of hardware IP and software platform configuration changes required to make the hardware platform Linux ready. These are described below:

### Zynq UltraScale+ MPSoC

The following is a list of hardware requirements for a Zynq® UltraScale+™ MPSoC hardware project to boot Linux:

1. External memory controller with at least 64 MB of memory (Required)
2. UART (Optional, but required for serial console)

---

**IMPORTANT:** *If soft IP is used, ensure the interrupt signal is connected*

---

3. Non-volatile memory (Optional) e.g., QSPI Flash, SD/MMC
4. Ethernet (Optional, essential for network access)

---

**IMPORTANT:** *If soft IP with interrupt or external PHY device with interrupt is used, ensure the interrupt signal is connected*

---

### Zynq-7000

The following is a list of hardware requirements for a Zynq-7000 hardware project to boot Linux:

1. One Triple Timer Counter (TTC) (Required).

---

**IMPORTANT:** *If multiple TTCs are enabled, the Zynq-7000 Linux kernel uses the first TTC block from the device tree. Please make sure the TTC is not used by others.*

---

2. External memory controller with at least 32 MB of memory (Required)
3. UART (Optional, but required for serial console)

---

**IMPORTANT:** *If soft IP is used, ensure the interrupt signal is connected.*

---

4. Non-volatile memory (Optional) e.g., QSPI Flash, SD/MMC
5. Ethernet (Optional, essential for network access)

---

**IMPORTANT:** *If soft IP with interrupt or external PHY device with interrupt is used, ensure the interrupt signal is connected.*

---

## MicroBlaze (AXI)

The following is a list of requirements for a MicroBlaze™ hardware project to boot Linux:

1. IP core check list:
  - External memory controller with at least 32 MB of memory (Required)
  - Dual channel timer with interrupt connected (Required)
  - UART with interrupt connected (Optional, but required for serial console)
  - Non-volatile memory such as Linear Flash or SPI Flash (Optional)
  - Ethernet with interrupt connected (Optional, but required for network access)
2. MicroBlaze CPU configuration:
  - MicroBlaze with MMU support by selecting either Linux with MMU or Low-end Linux with MMU configuration template in the MicroBlaze configuration wizard.

---

**IMPORTANT:** Do not disable any instruction set related options that are enabled by the template, unless you understand the implications of such a change.

---

- The MicroBlaze initial bootloader, called FS-BOOT, has a minimum BRAM requirement. 4K Byte is required for Parallel flash and 8K Byte for SPI flash when the system boots from non-volatile memory

---

## Export Hardware Platform to PetaLinux Project

This section describes how to export hardware platform to PetaLinux Project.

### Prerequisites

This section assumes that a hardware platform is created with the Vivado design suite. Refer to section [Create Hardware Platform with Vivado](#) for more information.

### Exporting Hardware Platform

After you have configured your hardware project, build the hardware bitstream. The PetaLinux project requires a hardware description file (.hdf file) with information about the processing system. You can get the hardware description file by running "Export Hardware" from Vivado.

PetaLinux tools can generate a device tree source file, u-boot config header files, and enable some Xilinx IP kernel drivers based on the hardware description file. This will be described in later sections.

For Zynq UltraScale+ MPSoC platform, you need to boot with the Power Management Unit (PMU) firmware. You will also need to build the PMU firmware with XSDK. Refer to *Zynq UltraScale+ MPSoC Software Developer Guide* (UG1137) [Ref 3], for details on how to build the PMU firmware with XSDK.

---

## Create a New PetaLinux Project

This section describes how to create a new PetaLinux project.

### Prerequisites

This section assumes that the PetaLinux Working Environment Setup is complete. Refer to section [PetaLinux Working Environment Setup](#) for more details.

### Create New Project

The `petalinux-create` command is used to create a new PetaLinux project:

```
$ petalinux-create --type project --template <CPU_TYPE> --name  
<PROJECT_NAME>
```

The parameters are as follows:

- `--template <CPU_TYPE>` - The supported CPU types are Zynq Ultrascale+ MPSoC, Zynq and MicroBlaze.
- `--name <PROJECT_NAME>` - The name of the project you are building.

This command will create a new PetaLinux project folder from a default template. Later steps customize these settings to match the hardware project created previously.

---

**TIP:** For details of PetaLinux project structure, refer to [Appendix A, PetaLinux Project Structure](#).

---

---

**CAUTION!** When a PetaLinux project is created on NFS, it changes the `TMPDIR` to `/tmp/<projname_timestamp>`. If `/tmp/<projname_timestamp>` is also on NFS, it will throw an error. If you want to change the `TMPDIR` to a local storage use `petalinux-config --> Yocto-settings --> TMPDIR`.

---

---

## Version Control

This section details about version management/control in PetaLinux project.

### Prerequisites

This section assumes that the you have created a new PetaLinux project or have an existing PetaLinux project. Refer to section [Create a New PetaLinux Project](#) for more information on creating the PetaLinux project.

### Version Control

You can have version control over your PetaLinux project directory "`<plnx-proj-root>`" excluding the following:

- "`<plnx-proj-root>/petalinux`"
- "`<plnx-proj-root>/build`"
- "`<plnx-proj-root>/images`"

---

## Import Hardware Configuration

This Section explains how to update an existing/newly created PetaLinux project with a new hardware configuration. This enables you to make PetaLinux Tools' software platform ready for building a Linux system, customized to your new hardware platform.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have exported the hardware platform and `.hdf` file is generated. Refer to section [Exporting Hardware Platform](#).
- You have created a new PetaLinux project or have an existing PetaLinux project. Refer to section [Create a New PetaLinux Project](#) for more information on creating the PetaLinux project.

## Steps to Import Hardware Configuration

Steps to import hardware configuration are:

1. Change into the directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Import the hardware description with `petalinux-config` command, by giving the path of the directory containing the `.hdf` file (For example: `hwproject/hwproject.sdk/hwproject_design_wrapper_hw_platform_0`) as follows:

```
$ petalinux-config
--get-hw-description=<path-to-directory-which-contains-hardwaredescription- file>
```

This launches the top system configuration menu when `petalinux-config --get-hw-description` runs first time for the PetaLinux project or the tool detects there is a change in the system primary hardware candidates:

```
Linux Components Selection --->
Auto Config Settings --->
-* Subsystem AUTO Hardware Settings --->
Kernel Bootargs --->
ARM Trusted Firmware Compilation Configuration --->
u-boot Configuration --->
Image Packaging Configuration --->
Firmware Version Configuration --->
Yocto Settings --->
```

Make sure "Subsystem AUTO Hardware Settings --->" is selected, and go into the menu which is similar to the following:

```
--- Subsystem AUTO Hardware Settings
System Processor (psu_cortexa53_0) --->
Memory Settings --->
Serial Settings --->
Ethernet Settings --->
Flash Settings --->
SD/SDIO Settings --->
RTC Settings --->
[*] Advanced bootable images storage Settings --->
```

"Subsystem AUTO Hardware Settings --->" menu allows customizing system wide hardware settings.

This step may take a few minutes to complete. This is because the tool will parse the hardware description file for hardware information required to update the device tree, PetaLinux u-boot configuration files and the kernel config files based on the "Auto Config Settings --->" and "Subsystem AUTO Hardware Settings --->" settings.

For example, if `ps7_ethernet_0` as the Primary Ethernet is selected and user enables auto update for kernel config and u-boot config, the tool will automatically enable its

kernel driver and also updates the u-boot configuration headers for u-boot to use the selected ethernet controller.

**Note:** For more details on Auto Config Settings menu, refer to [Appendix C, Auto Config Settings](#).

## Build System Image

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system, customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more details.

### Steps to Build PetaLinux System Image

1. Change into the directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Run `petalinux-build` to build the system image:

```
$ petalinux-build
```

The console shows the compilation progress. For example:

```
[INFO] building project
[INFO] sourcing bitbake
INFO: bitbake petalinux-user-image
Loading cache: 100%
|#####| ETA: 00:00:00
Loaded 2927 entries from dependency cache.
Parsing recipes: 100%
|#####| Time: 00:00:02
Parsing of 2315 .bb files complete (2278 cached, 37 parsed). 2931 targets, 193
skipped, 0 masked, 0 errors.
NOTE: Resolving any missing task queue dependencies
NOTE: Preparing RunQueue
NOTE: Checking sstate mirror object availability (for 901 objects)
NOTE: Executing SetScene Tasks
NOTE: Executing RunQueue Tasks
NOTE: Tasks Summary: Attempted 2442 tasks of which 2006 didn't need to be rerun and
all succeeded.
Summary: There were 16 WARNING messages shown.
INFO: generating FIT Image
INFO: bitbake petalinux-user-image -c do_image_xilinx_fitimage -R
/home/user/xilinx-zcu102-v2016.4/build/conf/fit-image.conf
Parsing recipes: 100%
|#####| Time: 00:00:13
```

```
Parsing of 2315 .bb files complete (0 cached, 2315 parsed). 2931 targets, 193
skipped, 0 masked, 0 errors.
NOTE: Resolving any missing task queue dependencies
NOTE: Preparing RunQueue
NOTE: Checking sstate mirror object availability (for 113 objects)
NOTE: Executing SetScene Tasks
NOTE: Executing RunQueue Tasks
NOTE: Tasks Summary: Attempted 1971 tasks of which 1956 didn't need to be rerun and
all succeeded.

Summary: There were 2 WARNING messages shown.
INFO: Copying Images from deploy to images
INFO: Creating images/linux directory
[INFO] successfully built project
```

The full compilation log "build.log" is stored in the build subdirectory of your PetaLinux project. The Linux software images and the device tree are generated in the images/linux subdirectory of your PetaLinux project.

---

**IMPORTANT:** *By default, besides the kernel, rootfs and u-boot, the PetaLinux project is configured to generate and build the first stage bootloader. Refer to [Appendix B, Generating First Stage Bootloader Within Project](#) for more details on the auto generated first stage bootloader.*

---

## Generate uImage

When you run `petalinux-build`, it will generate FIT image for Zynq family devices and MicroBlaze platforms and RAM disk image `urootfs.cpio.gz` will also be generated. If you want to use `uImage` instead, you can use "`petalinux-package --image`" instead. For example:

```
$ petalinux-package --image -c kernel --format uImage
```

The `uImage` will be generated to `images/linux` subdirectory of your PetaLinux project. You will then need to configure your `u-boot` to boot with `uImage`. If you have selected "PetaLinux u-boot config" as your `u-boot` config target, you can modify "`<plnx-proj-root>/project-spec/meta-user/recipes-bsp/u-boot/files/platform-top.h`" of your PetaLinux project to overwrite the `CONFIG_EXTRA_ENV_SETTINGS` macro to define your `u-boot` boot command to boot with `uImage`.

## Troubleshooting

This section describes some common issues you may experience while building PetaLinux system images.

Table 1-8: Build System Image Troubleshooting

Problem / Error Message	Description and Solution
<pre>[ERROR] &lt;path-to-installed-PetaLinux &gt; /etc/build/common.mk:17: *** "No architecture is defined!". Stop.</pre>	<p><b>Problem Description:</b> This error message indicates that <code>petalinux-build</code> process cannot be completed because PetaLinux tools cannot understand hardware architectural definition.</p> <p><b>Solution:</b> You have to choose board and device appropriately in Vivado Hardware Project and import hardware description. Refer to section <a href="#">Import Hardware Configuration</a>.</p>

## Generate Boot Image for Zynq Family Devices

This section is for Zynq family devices only and describes how to generate `BOOT.BIN`.

### Prerequisites

This section assumes that you have built PetaLinux system image. Refer to section [Build System Image](#) for more information.

### Generate Boot Image

Before executing this step, ensure you have built the hardware bitstream. The boot image can be put into Flash or SD card. When you power on the board, it can boot from the boot image. A boot image usually contains a first stage bootloader image, FPGA bitstream, PMU firmware and u-boot.

Follow the step below to generate the boot image in ".bin" format.

```
$ petalinux-package --boot --fsbl <FSBL image> --fsbl <FSBL image> --pmufw
<PATH_TO_PMU_FW_ELF> --u-boot
```

For detailed usage, refer to the `--help` option or *PetaLinux Tools Documentation: PetaLinux Command Line Reference* (UG1157) [\[Ref 4\]](#).

---

## Generate Boot Image for Zynq UltraScale+ MPSoC

This section is for Zynq UltraScale+ MPSoC only and describes how to generate `BOOT.BIN` for Zynq UltraScale+ MPSoC. Skip this section for MicroBlaze and Zynq targets.

### Prerequisites

This section assumes that you have built PetaLinux system image. For more information, refer [Build System Image](#).

### Generate Boot Image

Before executing this step, ensure you have built the hardware bitstream. The boot image can be put into Flash or SD card. When you power on the board, it can boot from the boot image. A boot image usually contains a first stage bootloader image, FPGA bitstream and u-boot.

Follow the step below to generate the boot image in ".bin" format.

```
$ petalinux-package --boot --fsbl <FSBL image> --fpga <FPGA bitstream> --u-boot
```

For detailed usage, refer to the `--help` option or *PetaLinux Tools Documentation: PetaLinux Command Line Reference* (UG1157) [\[Ref 4\]](#).

---

## Generate Boot Image for MicroBlaze

This section is for MicroBlaze only and describes how to generate MCS file for MicroBlaze.

### Prerequisites

This section assumes that you have built the PetaLinux system image. For more information, refer [Build System Image](#).

### Generate Boot Image

Execute the following command to generate MCS boot file for MicroBlaze.

```
$ petalinux-package --boot --fpga <FPGA bitstream> --u-boot --kernel
```

It will generate `boot.mcs` in your working directory and it will be copied to the `<plnx-proj-root>/<proj>/images/linux/` directory. With the above command, the MCS file contains `fpga bit`, `fs-boot`, `u-boot` and kernel image `image.ub`.

Command to generate `.mcs` file with fs-boot and fpga only:

```
$ petalinux-package --boot --fpga <FPGA bitstream>
```

Command to generate `.mcs` file with fpga, fs-boot and u-boot:

```
$ petalinux-package --boot --fpga <FPGA bitstream> --u-boot
```

For detailed usage, refer to the `--help` option or document *PetaLinux Tools Documentation: PetaLinux Command Line Reference* (UG1157) [Ref 4].

---

## Package Prebuilt Image

This section describes how to package newly built images into prebuilt directory.

**Note:** This step helps in making use of prebuilt capability to boot with JTAG/QEMU. This step is not mandatory to boot with JTAG/QEMU.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- For Zynq family devices, you have generated boot image. For more information, refer to [Generate Boot Image for Zynq Family Devices](#).
- For MicroBlaze, you have generated system image, refer to [Build System Image](#).

### Steps to Package Prebuilt Image

1. Change into the root directory of your project.

```
$ cd <plnx-proj-root>
```

2. Use `petalinux-package --prebuilt` to package the prebuilt images:

```
$ petalinux-package --prebuilt --fpga <FPGA bitstream>
```

For detailed usage, refer to the `--help` option or document *PetaLinux Tools Documentation: PetaLinux Command Line Reference* (UG1157) [Ref 4].

## Using petalinux-boot Command with Prebuilt Images

Booting a PetaLinux Image is achieved with the `petalinux-boot` command, along with `--qemu` option to boot the image under software emulation (QEMU) and `--jtag` on a hardware board. This section describes different boot levels for prebuilt option.

### Prerequisites

This section assumes that you have packaged prebuilt images. Refer to [Package Prebuilt Image](#).

### Boot Levels for Prebuilt Option

`--prebuilt <BOOT_LEVEL>` boots prebuilt images (override all settings). Supported boot level is 1 to 3.

- Level 1: Download the prebuilt FPGA bitstream
  - It will also boot FSBL for Zynq-7000 and Zynq UltraScale+ MPSoC
- Level 2: Download the prebuilt FPGA bitstream and boot the prebuilt u-boot.
  - For Zynq-7000: it will also boot FSBL before booting u-boot.
  - For Zynq UltraScale+ MPSoC: it will also boot FSBL, PMU firmware and then Arm Trusted Firmware (ATF) before booting u-boot.
- Level 3:
  - For MicroBlaze: Download the prebuilt FPGA bitstream and boot the prebuilt kernel image on target.
  - For Zynq-7000: Download the prebuilt FPGA bitstream and FSBL and boot the prebuilt u-boot and boot the prebuilt kernel on target.
  - For Zynq UltraScale+ MPSoC: Download the prebuilt FPGA bitstream, the prebuilt FSBL, the prebuilt PMUFW, the prebuilt ATF and the prebuilt kernel on target.

Example to show the usage of boot level for prebuilt option:

```
$ petalinux-boot --jtag --prebuilt 3
```

## Boot a PetaLinux Image on QEMU

This section describes how to boot a PetaLinux image under software emulation (QEMU) environment.

**Note:** For the details on Xilinx IP models supported by QEMU, refer to Appendix E Xilinx IP models supported by QEMU.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have a PetaLinux system image by either installing a PetaLinux BSP (refer to section [PetaLinux BSP Installation](#)) or by building your own PetaLinux project (refer to [Build System Image](#)).
- If you are going to use `--prebuilt` option for QEMU boot, you will also need to have prebuilt images packaged, refer to [Package Prebuilt Image](#).

**IMPORTANT:** Unless otherwise indicated, the PetaLinux tool command must be run within a project directory ("`<plnx-proj-root>`").

### Steps to Boot a PetaLinux Image on QEMU

PetaLinux provides QEMU support to enable testing of PetaLinux software image in a simulated environment without any hardware.

To test the PetaLinux reference design with QEMU, follow these steps:

1. Change to your project directory and boot the prebuilt linux kernel image:

```
$ petalinux-boot --qemu --prebuilt 3
```

**Note:** If you do not wish to use prebuilt capability for QEMU boot, refer to Additional Options for Booting on QEMU.

- The `--qemu` option tells `petalinux-boot` to boot QEMU, instead of real hardware via JTAG, and the `--prebuilt 3` boots the linux kernel.

**TIP:** To know more about different boot levels for prebuilt option, refer to [Using petalinux-boot Command with Prebuilt Images](#).

The example of the kernel boot log messages displayed on the serial console during successful `petalinux-kernel`, is shown below:

```
[ 13.425611] Freeing unused kernel memory: 13508K (ffff8008b3f000 -
ffff8009870000)
[ 35.313611] random: dd urandom read with 2 bits of entropy available
```

```
[ 38.295984] IPv6: ADDRCONF(NETDEV_UP): eth0: link is not ready
[ 40.197703] macb ff0e0000.ethernet eth0: unable to generate target frequency:
25000000 Hz
[ 40.198986] macb ff0e0000.ethernet eth0: link up (100/Full)
[ 40.200116] IPv6: ADDRCONF(NETDEV_CHANGE): eth0: link becomes ready
```

```
PetaLinux 2016.4 plnx_aarch64 /dev/ttyPS0
```

```
plnx_aarch64 login: root
(ctrl+A then X)
root@plnx_aarch64:~# QEMU: Terminated
```

2. Login to PetaLinux with the default user name `root` and password `root`.

---

**TIP:** To exit QEMU, press `Ctrl+A` together, release and then press `X`.

---

## Additional Options for Booting on QEMU

- To download newly built `<plnx-proj-root>/images/linux/u-boot.elf` with QEMU:

```
$ petalinux-boot --qemu --u-boot
```

- For MicroBlaze and Zynq-7000, it will boot `<plnx-proj-root>/images/linux/u-boot.elf` with QEMU.
- For Zynq UltraScale+ MPSoC, it loads the `<plnx-proj-root>/images/linux/u-boot.elf` and boots the ATF image `<plnx-proj-root>/images/linux/bl31.elf` with QEMU, and the ATF will then boot the loaded u-boot image.

- To download newly built kernel with qemu:

```
$ petalinux-boot --qemu --kernel
```

- For MicroBlaze, it will boot `<plnx-proj-root>/images/linux/image.elf` with QEMU.
- For Zynq-7000, it will boot `<plnx-proj-root>/images/linux/zImage` with QEMU.
- For Zynq UltraScale+ MPSoC, it loads the kernel image `<plnx-proj-root>/images/linux/Image` and boots the ATF image `<plnx-proj-root>/images/linux/bl31.elf` with QEMU, and the ATF will then boot the loaded kernel image.

- Direct Boot a Linux Image with Specific DTB:

Device Trees (DTB files) are used to describe the hardware architecture and address map to the Linux kernel. The PetaLinux system emulator also uses DTB files to dynamically configure the emulation environment to match your hardware platform.

If no DTB file option is provided, `petalinux-boot` extracts the DTB file from the given `image.elf` for Microblaze and from

"<plnx-proj-root>/images/linux/system.dtb" for Zynq-7000 and Zynq UltraScale+ MPSoC. Alternatively, you can use the `--dtb` option as follows:

```
$ petalinux-boot --qemu --image ./images/linux/zImage --dtb
./images/linux/system.dtb
```

**Note:** QEMU version has been upgraded to 2.6. The old options are deprecated in new version, they functionally operational. PetaLinux tools still use old options, therefore it gets warning messages, which can be ignored.

Warning message for Zynq UltraScale+ MPSoC:

```
qemu-system-aarch64: -tftp /ssd/yocto/4-1210/xilinx-zc702-2016.4/images/linux: The
-tftp option is deprecated. Please use '-netdev user,tftp=... ' instead.g
```

## Boot a PetaLinux Image on Hardware with SD Card

This section describes how to boot a PetaLinux image on Hardware with SD Card.

**Note:** This section is for Zynq-7000 and Zynq UltraScale+ MPSoC only, since they allow you to boot from SD card.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have installed PetaLinux Tools on the Linux workstation. If you have not installed, refer to section [Installation Steps](#).
- You have installed PetaLinux BSP on the Linux workstation. If you have not installed, refer to section [PetaLinux BSP Installation](#).
- A serial communication program such as minicom/kermit/gtkterm has been installed; the baud rate of the serial communication program has been set to 115200 bps.

### Steps to Boot a PetaLinux Image on Hardware with SD Card

1. Mount the SD card on your host machine.
2. Copy the following files from <plnx-proj-root>/pre-built/linux/images/ into the root directory of the first partition which is in FAT32 format in the SD card:
  - BOOT.BIN
  - image.ub
3. Connect the serial port on the board to your workstation.

4. Open a console on the workstation and start the preferred serial communication program (For example: kermit, minicom, gkterm) with the baud rate set to 115200 on that console.
5. Power off the board.
6. Set the boot mode of the board to SD boot. Refer to the board documentation for details.
7. Plug the SD card into the board.
8. Power on the board.
9. Watch the serial console, you will see the boot messages similar to the following:

```
Freeing unused kernel memory: 460K (ffffff8008b3d000 - fffffff8008bb0000)
INIT: version 2.88 booting
[ 4.912645] FAT-fs (mmcblk0p1): Volume was not properly unmounted. Some data may be
corrupt. Please run fsck.
[ 5.235523] random: dd urandom read with 8 bits of entropy available
Wed Nov 2 21:27:25 UTC 2016
INIT: Entering runlevel: 5
Configuring network interfaces... ifconfig: SIOCGIFFLAGS: No such device
Starting system message bus: dbus.
Starting Dropbear SSH server: Generating key, this may take a while...
Public key portion is:

plnx_aarch64 login: root
root@plnx_aarch64:~#
```

---

**TIP:** If you wish to stop auto-boot, hit any key when you see the messages similar to the following on the console: **Hit any key to stop autoboot:**

---

10. Type user name `root` and password `root` on the serial console to log into the PetaLinux system.

## Troubleshooting

This section describes some common issues you may experience while booting a PetaLinux image on hardware with SD card.

Table 1-9: PetaLinux Image on Hardware Troubleshooting

Problem / Error Message	Description and Solution
Wrong Image Format for boot command. ERROR: Can't get kernel image!	<p><b>Problem Description:</b>                      This error message indicates that the <code>u-boot</code> bootloader is unable to find kernel image. This is likely because <code>bootcmd</code> environment variable is not set properly.</p> <p><b>Solution:</b>                      To see the default boot device, print <code>bootcmd</code> environment variable using the following command in u-boot console.</p> <pre>U-Boot-PetaLinux&gt; print bootcmd</pre> <p>If it is not boot from SD card by default, there are a few options as follows,</p> <ul style="list-style-type: none"> <li>Without rebuild PetaLinux, set <code>bootcmd</code> to boot from your desired media, use <code>setenv</code> command. For SD card boot, set the environment variable as follows.</li> </ul> <pre>U-Boot-PetaLinux&gt; setenv bootcmd 'run sdboot' ; saveenv</pre> <ul style="list-style-type: none"> <li>Run <code>petalinux-config</code> to set to load kernel image from SD card. Refer to section <a href="#">Boot Images Storage Configuration</a>. Rebuild PetaLinux and regenerate <code>BOOT.BIN</code> with the rebuilt u-boot, and then use the new <code>BOOT.BIN</code> to boot the board. Refer to section <a href="#">Generate Boot Image for Zynq Family Devices</a> on how to generate <code>BOOT.BIN</code>.</li> </ul>

**TIP:** To know more about u-boot options, use the command: `$ U-Boot-PetaLinux> printenv`

## Boot a PetaLinux Image on Hardware with JTAG

This section describes how to boot a PetaLinux image on hardware with JTAG.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have a PetaLinux system image by either installing a PetaLinux BSP (refer to section [PetaLinux BSP Installation](#)) or by building your own PetaLinux project (refer to section [Build System Image](#)).
- This is optional and only needed if you wish to make use of prebuilt capability for JTAG boot. You have packaged prebuilt images, refer to section [Package Prebuilt Image](#).

- A serial communication program such as minicom/kermit/gtkterm has been installed; the baud rate of the serial communication program has been set to 115200bps.
- Appropriate JTAG cable drivers have been installed. You can download drivers from [Digilent Adept Downloads](#).

## Steps to Boot a PetaLinux Image on Hardware with JTAG

1. Power off the board.
2. Connect the JTAG port on the board with the JTAG cable to your workstation.
3. Connect the serial port on the board to your workstation.
4. If your system has ethernet, also connect the Ethernet port on the board to your local network.
5. For Zynq family device boards, ensure that the mode switches are set to JTAG mode. Refer to the board documentation for details.
6. Power on the board.
7. Open a console on your workstation and start with preferred serial communication program (For example, kermit, minicom) with the baud rate set to 115200 on that console.
8. Run the petalinux-boot command as follows on your workstation:

```
$ petalinux-boot --jtag --prebuilt 3
```

**Note:** If you wish not to use prebuilt capability for JTAG boot, refer to Additional options for booting with JTAG.

The `--jtag` option tells `petalinux-boot` to boot on hardware via JTAG, and the `--prebuilt 3` option boots the linux kernel. Wait for the appearance of the shell prompt on the command console to indicate completion of the command.

**Note:** To know more about different boot levels for prebuilt option, refer to [Using petalinux-boot Command with Prebuilt Images](#).

The example of the message on the workstation command console for successful `petalinux-boot` is:

```
$ petalinux-boot --jtag --prebuilt 3
INFO: Launching XSDB for file download and boot.
INFO: This may take a few minutes, depending on the size of your image.
INFO: Configuring the FPGA...
INFO: Downloading bitstream to the target.
INFO: Downloading ELF file to the target.
INFO: Downloading ELF file to the target.
INFO: Downloading ELF file to the target.
INFO: Downloading ELF file to the target.
```

The example of the message on the serial console for successful `petalinux-boot` is:

```
[ 6.463766] Freeingunusedkernelmemory:13508K(ffffff8008b3d000-ffffff80
0986e000)
[ 6.691711] mmc0: new high speed SDHC card at address 0007
[ 6.702259] mmcblk0: mmc0:0007 SD04G 3.68 GiB
[ 6.707767] mmcblk0: p1
[ 7.672348] random: dd urandom read with 8 bits of entropy available
[ 7.758876] IPv6: ADDRCONF(NETDEV_UP): eth0: link is not ready
[ 9.738520] macb ff0e0000.ethernet eth0: link up (1000/Full)
[ 9.744128] IPv6: ADDRCONF(NETDEV_CHANGE): eth0: link becomes ready
```

```
PetaLinux 2016.4 plnx_aarch64 /dev/ttyPS0
```

```
plnx_aarch64 login:
```

By default, network settings for PetaLinux reference designs are configured using DHCP. The output you see may be slightly different from the above example, depending on the PetaLinux reference design being tested.

9. Type user name `root` and password `root` on the serial console to log into the PetaLinux system.
10. Determine the IP address of the PetaLinux by running `ifconfig` on the system console.

Additional options for booting with JTAG

- To download a bitstream to target board:

```
$ petalinux-boot --jtag --fpga --bitstream <BITSTREAM>
```

- To download newly built `<plnx-proj-root>/images/linux/u-boot.elf` to target board:

```
$ petalinux-boot --jtag --u-boot
```

- To download newly built kernel to target board:

```
$ petalinux-boot --jtag --kernel
```

- For MicroBlaze, this will boot `<plnx-proj-root>/images/linux/image.elf` on target board.
- For Zynq-7000, this will boot `<plnx-proj-root>/images/linux/zImage` on target board.
- For Zynq UltraScale+ MPSoC, this will boot `<plnx-proj-root>/images/linux/Image` on target board.

- To Download a image with a bitstream with `--fpga --bitstream <BITSTREAM>` option:

```
$ petalinux-boot --jtag --u-boot --fpga --bitstream <BITSTREAM>
```

The above command will download the bitstream and then download the U-Boot image.

- To see the verbose output of jtag boot with `-v` option:

```
$ petalinux-boot --jtag --u-boot -v
```

- To download PMU firmware to target board with U-Boot:

```
$ petalinux-boot --jtag --pmufw <PATH_TO_PMUFW_ELF> --u-boot
```

## Logging Tcl/XSDB for JTAG Boot

Use the following command to take log of XSDB commands used during JTAG boot. It dumps tcl script (which in turn invokes the xsdb commands) data to `test.txt`.

```
$ cd <plnx-proj-root>
$ petalinux-boot --jtag --prebuilt 3 --tcl test.txt
```

## Troubleshooting

This section describes some common issues you may experience while booting a PetaLinux image on hardware with JTAG.

Table 1-10: PetaLinux Image on Hardware with JTAG Troubleshooting

Problem / Error Message	Description and Solution
ERROR: This tool requires 'xsdb' and it is missing. Please source Xilinx Tools settings first.	<p><b>Problem Description:</b> This error message indicates that PetaLinux tools can not find the xsdb tool that is a part of the Xilinx Vivado or SDK tools.</p> <p><b>Solution:</b> You have to setup Vivado Tools Working Environment. Refer to <a href="#">PetaLinux Working Environment Setup</a>.</p>
Cannot see any console output when trying to boot U-Boot or kernel on hardware but boots correctly on QEMU.	<p><b>Problem Description:</b> This problem is usually caused by one or more of the following:</p> <ul style="list-style-type: none"> <li>The serial communication terminal application is set with the wrong baud rate.</li> <li>Mismatch between hardware and software platforms.</li> </ul> <p><b>Solution:</b></p> <ul style="list-style-type: none"> <li>Ensure your terminal application baud rate is correct and matches your hardware configuration.</li> <li>Ensure the PetaLinux project is built with the right hardware platform. <ul style="list-style-type: none"> <li>Import hardware configuration properly, refer to section Import Hardware Configuration.</li> <li>Check the "Subsystem AUTO Hardware Settings ---&gt;" submenu to make sure it matches the hardware platform.</li> <li>Check the "Serial settings ---&gt;" submenu under "Subsystem AUTO Hardware Settings ---&gt;" to ensure stdout, stdin are set to the correct UART IP core.</li> <li>Rebuild system images, refer to Build System Image.</li> </ul> </li> </ul>

## Boot a PetaLinux Image on Hardware with TFTP

This section describes how to boot a PetaLinux image using Trivial File Transfer Protocol (TFTP).

**TIP:** TFTP boot saves a lot of time because it is much faster than booting through JTAG and you do not have to flash the image for every change in kernel source.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- Host environment with TFTP server is setup and PetaLinux Image is built for TFTP boot. Refer to section [Configure TFTP Boot](#).
- You have packaged prebuilt images, refer to section [Package Prebuilt Image](#).
- A serial communication program such as minicom/kermit/gtkterm has been installed; the baud rate of the serial communication program has been set to 115200 bps.
- Ethernet connection is setup properly between Host and Linux Target.
- Appropriate JTAG cable drivers have been installed. You can download drivers from Digilent Adept Downloads.

### Steps to Boot a PetaLinux Image on Hardware with TFTP

1. Power off the board.
2. Connect the JTAG port on the board to the workstation using a JTAG cable with the JTAG cable.
3. Connect the serial port on the board to your workstation.
4. Connect the Ethernet port on the board to the local network via a network switch.
5. For Zynq family device boards, ensure that the mode switches are set to JTAG mode. Refer to the board documentation for details.
6. Power on the board.
7. Open a console on your workstation and start with preferred serial communication program (For example, kermit, minicom) with the baud rate set to 115200 on that console.
8. Run the petalinux-boot command as follows on your workstation.

```
$ petalinux-boot --jtag --prebuilt 2
```

The `--jtag` option tells `petalinux-boot` to boot on hardware via JTAG, and the `--prebuilt 2` option will download the prebuilt bitstream (and FSBL for Zynq) to target board, and then boot prebuilt u-boot on target board.

9. When autoboot starts, hit any key to stop it.

The example of a Workstation console output for successful u-boot download is:

```
U-Boot 2016.07 (Nov 02 2016 - 15:24:58 -0600) Xilinx ZynqMP ZCU102

I2C:   ready
DRAM:  4 GiB
EL Level:      EL2
Chip ID:      xczuunknown

reading image.ub
ZynqMP>
```

10. Check whether the TFTP server IP address is set to the IP Address of the host where the image resides. This can be done using the following command.

```
U-Boot-PetaLinux> print serverip
```

11. Set the server IP address to the host IP address using the following commands.

```
U-Boot-PetaLinux> set serverip <HOST IP ADDRESS>; saveenv
```

12. Boot the kernel using the following command.

```
U-Boot-PetaLinux> run netboot
```

## Troubleshooting

Table 1-11: PetaLinux Image on Hardware with TFTP

Problem / Error Message	Description and Solution
Error: "serverip" not defined.	<p><b>Problem Description:</b> This error message indicates that <code>u-boot</code> environment variable <code>serverip</code> is not set. You have to set it to IP Address of the host where the image resides.</p> <p><b>Solution:</b> Use the following command to set the <code>serverip</code>: U-Boot-PetaLinux&gt; set serverip &lt;HOST IP ADDRESS&gt;;saveenv</p>

## BSP Packaging

BSPs are useful for distribution in general and allude to Xilinx Worldwide Technical Support as a specific use case. Xilinx WTS requires a bare minimum design packaged as a PetaLinux BSP to get a testcase for further debugging and support. This section explains, with an example, how to package a BSP with PetaLinux project.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps for BSP Packaging

Steps on how to package a project for submission to WTS for debug are as follows:

1. You can go outside the PetaLinux project directory to run `petalinux-package` command.

2. Use the following commands to package the bsp.

```
$ petalinux-package --bsp -p <plnx-proj-root> --output MY.BSP
```

3. This will generate MY.BSP including the following elements from the specified project:

- `<plnx-proj-root>/project-spec/`
- `<plnx-proj-root>/config.project`
- `<plnx-proj-root>/petalinux/`
- `<plnx-proj-root>/pre-built/`
- all selected components

## Additional BSP Packaging Options

1. BSP packaging with hardware source.

```
$ petalinux-package --bsp -p <plnx-proj-root> \  
--hwsources <hw-project-root> --output MY.BSP
```

It will not modify the specified PetaLinux project <plnx-proj-root>. It will put the specified hardware project source to <plnx-proj-root>/hardware/ inside MY.BSP archive.

2. BSP packaging with external sources.

The support for search path is obsolete. It is your responsibility to copy the external sources under components/ext\_sources. Refer to [Using External Kernel and U-boot With PetaLinux](#) for more details. The BSP has to be packaged.

---

## Firmware Version Configuration

This section explains how to do firmware version configuration using `petalinux-config` command.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. For more information, refer to [Import Hardware Configuration](#).

### Steps for Firmware Version Configuration

1. Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Launch the top level system configuration menu.

```
$ petalinux-config
```

3. Select Firmware Version Configuration.
4. Select Host Name, Product Name, Firmware Version as per the requirement to edit them.
5. Exit the menu and select <Yes> when asked Do you wish to save your new configuration?:

```
Do you wish to save your new configuration ? <ESC><ESC>  
to continue.  
< Yes > < No >
```

---

## Root file system Type Configuration

This section details configuration of RootFS type using `petalinux-config` command.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps for Root file system Type Configuration

1. Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Launch the top level system configuration menu.

```
$ petalinux-config
```

3. Select Image Packaging Configuration.
4. Select Root file System type.
5. Select INITRAMFS/INITRD/JFFS2/NFS/SD card as per the requirement.
6. Save Configuration settings.

---

## Boot Images Storage Configuration

This section provides details about configuration of the Boot Device e.g. Flash, SD/MMC using `petalinux-config` command.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

## Steps for Boot Images Storage Configuration

1. Change into the root directory of your PetaLinux project.  

```
$ cd <plnx-proj-root>
```
2. Launch the top level system configuration menu.  

```
$ petalinux-config
```
3. Select Subsystem AUTO Hardware Settings.
4. Select Advanced Bootable Images Storage Settings.
5. Select boot image settings.
6. Select Image Storage Media.
7. Select boot device as per the requirement. To set flash as the boot device select `primary flash`. To make SD card as the boot device select `primary sd`.
8. Under the `Advanced Bootable Images Storage Settings` submenu, select kernel image settings.
9. Select Image Storage Media.
10. Select storage device as per the requirement. To set flash as the boot device select `primary flash`. To make SD card as the boot device select `primary sd`.
11. Save Configuration settings.

**TIP:** To select a menu/submenu which was deselected before, press the down arrow key (↓) to scroll down the menu or the up arrow key (↑) to scroll up the menu. Once the cursor is on the menu, then press "y". To deselect a menu/submenu, follow the same process and press "n" at the end.

## Troubleshooting

This section describes some common issues you may experience while working with boot device configuration.

Table 1-12: Boot Images Storage Troubleshooting

Problem / Error Message	Description and Solution
ERROR: Failed to config linux/kernel!	<p><b>Problem Description:</b> This error message indicates that it is unable to configure the linux-kernel component with menuconfig.</p> <p><b>Solution:</b> Check whether all required libraries/packages are installed properly. Refer to section <a href="#">Installation Requirements</a>.</p>

---

## Primary Flash Partition Configuration

This sections provides details on how to configure flash partition with PetaLinux menuconfig.

1. Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Launch the top level system configuration menu.

```
$ petalinux-config
```

3. Select Subsystem AUTO Hardware Settings.
4. Select Flash Settings.
5. Select a flash device as the Primary Flash.
6. Set the name and the size of each partition.

**Note:** The PetaLinux tools uses the boot, bootenv (it is for u-boot environment variables) and kernel partitions to generate the u-boot commands:

The PetaLinux tools uses the start address for parallel flash or start offset for SPI flash and the size of the above partitions to generate the following u-boot commands:

- `update_boot` if the boot image, which is a u-boot image for MicroBlaze, a `BOOT.BIN` image for Zynq family devices, is selected to be stored in the primary flash.
- `update_kernel`, and `load_kernel` if the kernel image which is the FIT image `image.ub`, is selected to be stored in the flash.

---

## Base Root File System Configuration

This section talks about Base Root File System Configuration.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

## Steps for Base Root File System Configuration

1. Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Launch the top level system configuration menu.

```
$ petalinux-config
```

3. Select linux Components Selection

4. Select petalinux-rootfs as rootfs.

## Managing Image Size

In an embedded environment, it is very important to reduce the size of the kernel image stored in flash and the static size of kernel image in RAM. This section describes impact of `config` item on kernel size and RAM usage.

FIT image is the default bootable image format. By default the FIT image is composed of kernel image, DTB and rootfs image.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps for Managing Image Size

FIT Image size can be reduced using the following methods:

1. Launch the RootFS configuration menu using the following command:

```
$ cd <plnx-proj-root>
$ petalinux-config -c rootfs
```

Select Filesystem Packages. Under this submenu, you can find the list of options corresponding to RootFS packages. If your requirement does not need some of these packages, you can shrink the size of RootFS image by disabling them.

2. Launch the kernel configuration menu using the following command:

```
$ cd <plnx-proj-root>
$ petalinux-config -c kernel
```

Select General Setup. Under this submenu, you can find options to set the `config` items. Any item that is not mandatory to have in the system can be disabled to reduce the kernel image size. For example, `CONFIG_SHMEM`, `CONFIG_AIO`, `CONFIG_SWAP`, `CONFIG_SYSVIPC`. For more details, refer Linux kernel documentation.

---

**CAUTION!** *Note that disabling of some `config` items may lead to unsuccessful boot. So it is expected that the user has knowledge of `config` items before disabling them.*

---

---

**TIP:** *Inclusion of extra config items and Filesystem packages lead to increase in the kernel image size and RootFS size respectively.*

---

**Note:** If kernel size is more, you need to enable `BOOTLEN` flag in `platform-top.h` of `u-boot`.

---

## Configuring INITRAMFS Boot

INITRAMFS, abbreviated as initial RAM File System, is the successor of `initrd`. It is a `cpio` archive of the initial file system that gets loaded into memory during the PetaLinux startup process. The Linux kernel mounts it as `RootFS` and starts the initialization process.

This section describes how to configure INITRAMFS boot.

### Prerequisites

This section assumes that you have created a new PetaLinux project (refer to section [Create a New PetaLinux Project](#)) and imported the hardware platform (refer to section [Import Hardware Configuration](#)).

### Steps to Configure INITRAMFS Boot

1. Set the `RootFS` type to `INITRAMFS`. Refer to [Root file system Type Configuration](#).
2. Build the system image. Refer to [Build System Image](#).
3. Use one of the following methods to boot the system image.
  - a. Boot a PetaLinux Image on QEMU, refer to section [Boot a PetaLinux Image on QEMU](#).
  - b. Boot a PetaLinux Image on Hardware with SD Card, refer to section [Boot a PetaLinux Image on Hardware with SD Card](#).
  - c. Boot a PetaLinux Image on Hardware with JTAG, refer to section [Boot a PetaLinux Image on Hardware with JTAG](#).

---

**IMPORTANT:** *The default `RootFS` for PetaLinux is `INITRAMFS`.*

---

## Configure TFTP Boot

This section describes how to configure the Host and the PetaLinux image for Trivial File Transfer Protocol (TFTP) boot.

**TIP:** TFTP boot saves a lot of time because it is much faster than booting through JTAG and you do not have to flash the image for every change in kernel source.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have created a new PetaLinux project (refer to section [Create a New PetaLinux Project](#)) and imported the hardware platform (refer to section [Import Hardware Configuration](#)).
- You have TFTP server running on your host.

### PetaLinux Configuration and Build System Image

Steps to configure PetaLinux for TFTP boot and build the system image are:

1. Change to root directory of your PetaLinux project.  

```
$ cd <plnx-proj-root>
```
2. Launch the top level system configuration menu.  

```
$ petalinux-config
```
3. Select "Image Packaging Configuration".
4. Select "Copy final images to tftpboot" and set "tftpboot directory".
5. Save Configuration settings and build system image as explained in [Build System Image](#).

## Configuring NFS Boot

One of the most important components of a Linux system is the root file system. A good development root file system provides the developer with all the useful tools that can help him/her on his/her work. Such a root file system can become very big in size, so it is hard to store it in flash memory.

The most convenient thing is to mount the entire root file system from the network, allowing the host system and the target to share the same files. The root file system can be modified quickly and also on the fly (meaning that the file system can be modified while the system is running). The most common way to setup a system like the one described is through NFS.

---

**TIP:** *In case of NFS, no manual refresh is needed for new files.*

---

## Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have created a new PetaLinux project (refer to section [Create a New PetaLinux Project](#)) and imported the hardware platform (refer to section [Import Hardware Configuration](#)).
- You have Linux file and directory permissions.
- You have NFS server setup on your host.

## PetaLinux Configuration and Build System Image

Steps to configure the PetaLinux for NFS boot and build the system image are as follows:

1. Change to root directory of your PetaLinux project.  

```
$ cd <plnx-proj-root>
```
2. Launch the top level system configuration menu.  

```
$ petalinux-config
```
3. Select Image Packaging Configuration.
4. Select Root filesystem type.
5. Select NFS as the RootFS type.
6. Select Location of NFS root directory and set it to `/home/NFSshare`.
7. Exit menuconfig and save configuration settings. The bootargs in the auto generated DTSI will be updated with the PetaLinux loading rootfs from SD card default settings. You can check  

```
"<plnx-proj-root>/components/plnx_workspace/device-tree-generation/system-conf.dtsi"
```
8. Build the system image. Refer to section [Build System Image](#).

## Booting with NFS

In case of NFS Boot, RootFS is mounted through the NFS. But bootloader (fsbl, bitstream, u-boot) and kernel can be downloaded using various methods as mentioned below.

1. JTAG: In this case, bootloader and kernel will be downloaded on to the target through JTAG. Refer to [Boot a PetaLinux Image on Hardware with JTAG](#).

**TIP:** If you want to make use of prebuilt capability to boot with JTAG, package images into prebuilt directory. Refer to [Package Prebuilt Image](#).

2. TFTPBOOT: In this case, bootloader will be downloaded through JTAG and kernel will be downloaded on to the target through TFTPBOOT. Refer to [Boot a PetaLinux Image on Hardware with TFTP](#).
3. SD card: In this case, bootloader (BOOT.BIN) and kernel image (image.ub) will be copied to SD card and will be downloaded from SD card. Refer to [Boot a PetaLinux Image on Hardware with SD Card](#).

## Configuring SD Card ext filesystem Boot

This section describes how to configure SD Card ext filesystem boot.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have created a new PetaLinux project (refer to section [Create a New PetaLinux Project](#)) and imported the hardware platform (refer to section [Import Hardware Configuration](#)).
- An SD memory card with at least 4 GB of storage space. It is recommended to use a card with speed-grade 6 or higher to achieve optimal file transfer performance.

### Preparing the SD card

Steps to prepare the SD card for PetaLinux SD card ext filesystem boot:

1. The SD card is formatted with two partitions using a partition editor such as gparted.
2. The first partition should be at least 40 MB in size and formatted as a FAT32 filesystem. Ensure that there is 4MB of free space preceding the partition. The first partition will contain the bootloader, devicetree and kernel images. Label this partition as BOOT.

- The second partition should be formatted as an `ext4` filesystem and can take up the remaining space on the SD card. This partition will store the system root filesystem. Label this partition as `rootfs`.

---

**TIP:** For optimal performance make sure that the SD card partitions are 4 MB aligned.

---

## PetaLinux Configuration and Build System Image

Steps to configure PetaLinux for SD card ext filesystem boot and build the system image are as follows:

- Change to root directory of your PetaLinux project.  

```
$ cd <plnx-proj-root>
```
- Launch top level system configuration menu.  

```
$ petalinux-config
```
- Select Image Packaging Configuration.
- Select Root filesystem type.
- Select SD card as the RootFS type.
- Exit `menuconfig` and save configuration settings. The bootargs in the auto generated DTSI will be updated with the PetaLinux loading `rootfs` from SD card default settings. You can check  

```
"<plnx-proj-root>/components/plnx_workspace/device-tree-generation/system-conf.dtsi".
```
- Build PetaLinux images. For more information, refer to [Build System Image](#).
- Generate boot image. For more information, refer to section [Generate Boot Image for Zynq Family Devices](#).
- The generated `rootfs.cpio` file will be present in `images/linux` directory.

## Copying Image Files

This section explains how to copy image files to SD card partitions.

- Change to root directory of your PetaLinux project.  

```
$ cd <plnx-proj-root>
```
- Copy `BOOT.BIN` and `image.ub` to `BOOT` partition of SD card. The `image.ub` file will have device tree and kernel image files.  

```
$ cp images/linux/BOOT.BIN /media/BOOT/  
$ cp images/linux/image.ub /media/BOOT/
```

- Copy `rootfs.cpio` file to `rootfs` partition of SD card and extract the file system.

```
$ cp images/linux/rootfs.cpio /media/rootfs/
$ cd /media/rootfs
$ sudo pax -rvf rootfs.cpio
```

In order to boot this SD card ext image, refer to section [Boot a PetaLinux Image on Hardware with SD Card](#).

## Troubleshooting

Table 1-13: Configuring SD Card ext Filesystem Boot

Problem / Error Message	Description and Solution
EXT4-fs (mmcblk0p2): mounted filesystem with ordered data mode. Opts: (null) Kernel panic - not syncing: No working init found.	<p><b>Problem Description:</b> This message indicates that the Linux kernel is unable to mount EXT4 File System and unable to find working init.</p> <p><b>Solution:</b> Extract RootFS in <code>rootfs</code> partition of SD card. Refer to <a href="#">Extract RootFS</a> for more details</p>

## Including Prebuilt Applications

If an application is developed outside PetaLinux (for example, through Xilinx SDK), you may just want to add the application binary in the PetaLinux root file system. In this case, an application template is created to allow copying of the existing content to target filesystem.

This section explains how to include pre-compiled applications to PetaLinux root file system.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps to Include Prebuilt Applications

If your prebuilt application name is `myapp`, including this into PetaLinux root file system is explained in following steps.

- Ensure that the pre-compiled code has been compiled for your PetaLinux target architecture (For example, MicroBlaze, ARM etc.).
- Create an application with the following command.

```
$ petalinux-create -t apps --template install --name myapp --enable
```

3. Change to the newly created application directory.

```
$ cd <plnx-proj-root>/project-spec/meta-user/recipes-apps/myapp/files/
```

4. Remove existing myapp app and copy the prebuilt myapp.

```
$ rm myapp
$ cp <path-to-prebuilt-app> .
```

---

**IMPORTANT:** *You need to ensure that the binary data being installed into the target file system by an install template application is compatible with the underlying hardware implementation of your system.*

---

## Including Prebuilt Modules

If you have pre-compiled kernel modules, you may just want to add the module into PetaLinux root file system. This section explains how to include pre-compiled Modules to PetaLinux root file system.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps to Include Prebuilt Modules

If your prebuilt module name is mymodule, including this into PetaLinux root file system is explained in following steps:

1. Ensure that the pre-compiled kernel module has been compiled for your PetaLinux target architecture (For example, MicroBlaze, ARM etc.).
2. To create a module project, use the following command.

```
$ petalinux-create -t apps --template install --name mymodule --enable
```

3. Change to the newly created module directory.

```
$ cd <plnx-proj-root>/project-spec/meta-user/recipes-modules//mymodule/files
```

4. Place the pre-built library mymodule

```
$ cp <path-to-prebuilt-module>
```

5. Open the mymodule.bb file.

```
#
# This file is the mymodule recipe.
#

SUMMARY = "Simple mymodule application"
SECTION = "PETALINUX/apps"
LICENSE = "MIT"
LIC_FILES_CHKSUM =
"file://${COMMON_LICENSE_DIR}/MIT;md5=0835ade698e0bcf8506ecda2f7b4f302"

SRC_URI = "file://mymodule.ko \
"

S = "${WORKDIR}"

do_install() {
    install -d ${D}${base_libdir}/modules/${KERNEL_VERSION}/extra/
    install -m 0644 ${S}/mymodule.ko
    ${D}${base_libdir}/modules/${KERNEL_VERSION}/extra/
}

FILES_${PN} = "${base_libdir}/modules/"
```

---

## Adding Custom Applications

This section explains how to add custom applications to PetaLinux root file system.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps to Add Custom Applications

The basic steps are as follows:

1. Create a user application by running `petalinux-create -t apps` from inside a PetaLinux project on your workstation:

```
$ cd <plnx-proj-root>
$ petalinux-create -t apps [--template TYPE] --name <user-application-name> --enable
```

For example, to create a user application called `myapp` in `C` (the default):

```
$ petalinux-create -t apps --name myapp --enable
```

or:

```
$ petalinux-create -t apps --template c --name myapp --enable
```

To create a C++ application template, pass the `--template c++` option, as follows:

```
$ petalinux-create -t apps --template c++ --name myapp --enable
```

To create an autoconf application template, pass the `--template autoconf` option, as follows:

```
$ petalinux-create -t apps --template autoconf --name myapp --enable
```

The new application created can be found in the "`<plnx-proj-root>/project-spec/meta-user/recipes-apps/myapp`" directory.

2. Change to the newly created application directory.

```
$ cd <plnx-proj-root>/project-spec/meta-user/recipes-apps/myapp
```

You will see the following PetaLinux template-generated files:

**Table 1-14: Adding Custom Applications Template Generated Files**

Template	Description
<code>&lt;plnx-proj-root&gt;/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend</code>	Configuration file template - This file controls the integration of your application into the PetaLinux rootfs menu configuration. It also allows you select or de-select the app and its dev, dbg packages into the target root file system
Makefile	Compilation file template - This is a basic Makefile containing targets to build and install your application into the root filesystem. This file needs to be modified when you add additional source code files to your project.
README	A file to introduce how to build the user application.
myapp.c for C; myapp.cpp for C++	Simple application program in either C or C++, depending upon your choice.

**Note:** If you want to use the build artifacts for debugging with the third party utilities, add the following line:

```
RM_WORK_EXCLUDE += "myapp"
```

3. `myapp.c/myapp.cpp` file can be edited or replaced with the real source code for your application. Later if you want to modify your custom user application, this file should be edited.

**CAUTION!** You can delete the app directory if it is no longer required. Apart from deleting the app directory, you have to remove the line: `IMAGE_INSTALL_append= "myapp"` from `<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend`. Deleting the directory by keeping the mentioned line will throw an error.

## Adding Custom Modules

This section explains how to add custom kernel modules to PetaLinux root file system.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps to Add Custom Modules

1. Create a user module by running `petalinux-create -t modules` from inside a PetaLinux project on your workstation:

```
$ cd <plnx-proj-root>
$ petalinux-create -t modules --name <user-module-name> --enable
```

For example, to create a user module called `mymodule` in C (the default):

```
$ petalinux-create -t modules --name mymodule --enable
```

or:

```
$ petalinux-create -t modules --name mymodule --enable
```

You can use `-h` or `--help` to see the usage of the `petalinux-create -t modules`. The new module you have created can be found in the `<plnx-proj-root>/project-spec/meta-user/recipes-modules/mymodule` directory.

2. Change to the newly created module directory.

```
$ cd
<plnx-proj-root>/project-spec/meta-user/recipes-modules/mymodule
```

You will see the following PetaLinux template-generated files:

**Table 1-15: Adding Custom Modules Template-Generated Files**

Template	Description
Makefile	Compilation file template - This is a basic Makefile containing targets to build and install your module into the root filesystem. This file needs to be modified when you add additional source code files to your project.
README	A file to introduce how to build the user module.

Table 1-15: Adding Custom Modules Template-Generated Files (Cont'd)

Template	Description
mymodule.c	Simple kernel module in C.
<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend	Configuration file template - This file controls the integration of your application into the petalinux rootfs menu configuration system. It also allows you to select or de-select the app and its dev, dbg packages into the target root file system.

3. mymodule.c file can be edited or replaced with the real source code for your module. Later if you want to modify your custom user module, you should edit this file.

**Note:** If you want to use the build artifacts for debugging with the third party utilities, add the following line in myapp.bb:

```
RM_WORK_EXCLUDE += "myapp"
```

**CAUTION!** You can delete the module directory if it is no longer required. Apart from deleting the module directory, you have to remove the line: `IMAGE_INSTALL_append= "mymodule"` from `<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend`. Deleting the directory by keeping the mentioned line in `petalinux-image.bbappend` will throw an error.

## Building User Applications

This section explains how to build and install pre-compiled/custom user applications to PetaLinux root file system.

### Prerequisites

This section assumes that you have included pre-compiled applications to PetaLinux root file system (refer to section [Including Prebuilt Applications](#)) or added custom applications to PetaLinux root file system (refer to section [Adding Custom Applications](#)).

### Steps to Build User Applications

Running `petalinux-build` in the project directory "`<plnx-proj-root>`" will rebuild the system image including the selected user application myapp. (The output directory for this build process is

```
"<TMPDIR>/work/{ARCH}-xilinx-linux-gnueabi/myapp/1.0-r0")
```

```
$ petalinux-build
```

To build myapp into an existing system image:

```
$ cd <plnx-proj-root>
$ petalinux-build -c rootfs -x do_gen_sysroot
$ petalinux-build -c myapp
$ petalinux-build -x package
```

**Note:** `do_gen_sysroot` is to generate the sysroot based on the selected prebuilt packages options from the menuconfig. You do not have to always run `do_gen_sysroot` before building the application, but you need to run it at least once before you build the application.

Other `petalinux-build` options are explained with `--help`. Some of the build options are:

- To clean the selected user application:

```
$ petalinux-build -c myapp -x do_clean
```

- To rebuild the selected user application:

```
$ petalinux-build -c myapp -x build
```

This will just compile the application, the compiled executable files will be in `$(TMPDIR)/work/{ARCH}-xilinx-linux-gnueabi/myapp/1.0-r0/` directory.

**Note:** If you want to use the build artifacts for debugging with the third party utilities, add the line: `RM_WORK_EXCLUDE += "myapp"` in `<plnx-proj-root>/build/conf/local.conf`. Without this line the flag will remove all the executables after building.

To see all list of tasks for myapp: `petalinux-build -c myapp -x list_tasks`.

- To install the selected user application:

```
$ petalinux-build -c rootfs/myapp -x do_install
```

This will install the application into the target rootfs host copy:

```
<plnx-proj-root>/build/tmp/work/{MACHINE}-linux-gnueabi/petalinu
x-user-image/1.0-r0/rootfs/.
```

**Note:** `TMPDIR` can be found in `petalinux-config->Yocto-settings --> TMPDIR`. If the project is on local storage, `TMPDIR` is `<plnx-proj-root>/build/tmp/`.

For Zynq Ultrascale+ MPSoC:

ARCH: aarch64

MACHINE: plnx\_aarch64s

---

## Testing User Application

This section describes how to test a user application.

### Prerequisites

This section assumes that you have built and installed pre-compiled/custom user applications. Refer to section [Building User Applications](#).

### Steps to Test User Application

1. Boot the newly created system image.
2. Confirm that your user application is present on the PetaLinux system, by running the following command on the target system login console:

```
# ls /usr/bin
```

Unless you have changed the location of user application through its Makefile, the user application will be put in to "/usr/bin" directory.

3. Run your user application on the target system console. For example, to run user application myapp:

```
# myapp
```

4. Confirm that the result of the application is as expected.

If the new application is missing from the target filesystem, ensure that you have completed the `petalinuxbuild -x package` step as described in the previous section. This ensures that your application binary is copied into the root filesystem staging area, and that the target system image is updated with this new filesystem.

---

## Building User Modules

This section explains how to build and install pre-compiled/custom user kernel modules to PetaLinux root file system.

### Prerequisites

This section assumes that you have included pre-compiled applications to PetaLinux root file system (refer to section [Including Prebuilt Modules](#)) or added custom modules to PetaLinux root file system (refer to section [Adding Custom Modules](#)).

## Steps to Build User Modules

Running `petalinux-build` in the project directory "`<plnx-proj-root>`" will rebuild the system image including the selected user module `mymodule`. (The output directory for this build process is

```
<TMPDIR>/work/{ARCH}-xilinx-linux-gnueabi/mymodule/1.0-r0/)
```

```
$ petalinux-build
```

To build `mymodule` into an existing system image:

```
$ cd <plnx-proj-root>
$ petalinux-build -c mymodule
$ petalinux-build -x package
```

Other `petalinux-build` options are explained with `--help`. Some of the build options are:

- To clean the selected user module:

```
$ petalinux-build -c mymodule -x do_clean
```

- To rebuild the selected user module:

```
$ petalinux-build -c mymodule -x do_build
```

This will just compile the module, the compiled executable files will be in `<TMPDIR>/work/{ARCH}-xilinx-linux-gnueabi/mymodule/1.0-r0/` directory.

To see all list of tasks for this module: `petalinux-build -c mymodule -x list_tasks`.

- To install the selected user module:

```
$ petalinux-build -c mymodule -x do_install
```

This will install the module into the target rootfs host copy:

```
<plnx-proj-root>/build/tmp/work/{MACHINE}-linux-gnueabi/petalinux-user-image/1.0-r0/rootfs/.
```

**Note:** `TMPDIR` can be found in `petalinux-config->Yocto-settings --> TMPDIR`. If the project is on local storage, `TMPDIR` is `<plnx-proj-root>/build/tmp/`.

For Zynq Ultrascale+ MPSoC:

ARCH: `aarch64`

MACHINE: `plnx_aarch64s`

---

## PetaLinux Auto Login

This section explains how to login directly from boot without having to enter login credentials.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Steps for PetaLinux Auto Login

1. Open `<plnx-proj-root>/build/conf/local.conf`. and add `EXTRA_IMAGE_FEATURES="debug-tweaks"`
2. Open `<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-user-image.bb`. and delete the line: `"inherit extrausers"`
3. Delete the line: `"EXTRA_USERS_PARAMS = "usermod -P rrot root;"`  
`petalinux-build"`

---

**CAUTION!** `<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-user-image.bb` file will be regenerated for every `petalinux-config` and `petalinux-config -c rootfs`. Auto login will be provided as an option in `rootfs` menu config for the next release.

---

---

## Application Auto Run at Startup

This section explains how to add applications that run automatically at system startup.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

## Steps for Application Auto Run at Startup

If you have a prebuilt or newly created custom user application mystartup located in your PetaLinux project at `<plnx-proj-root>/project-spec/meta-user/recipes-apps/`, you may want to execute it at system startup. The steps to enable that are:

**TIP:** If you have prebuilt application and you have not included in PetaLinux Root file system, refer to [Including Prebuilt Applications](#).

If you want to create custom application and install it in PetaLinux Root file system, refer to [Adding Custom Applications](#).

If your auto run application is a blocking application which will never exit, launch this application as a daemon.

1. Change to the application directory.

```
<plnx-proj-root>/project-spec/meta-user/recipes-apps/mystartups/mystartup
```

2. Create `mystartup.sh` file with the following:

```
#!/bin/sh

start ()
{
echo " Start Hello PetaLinux."
# add your app
}

stop ()
{
echo " Stop Hello PetaLinux."
}

restart()
{
    stop
    start
}

case "$1" in
    start)    start; ;;
    stop)    stop; ;;
    restart) restart; ;;
    *)
        echo "Usage: $0 {start|stop|restart}"
        exit 1
esac

exit $?
```

3. Change to `project-spec/meta-user/recipes-apps/mystartup/`. Open `mystartup.bb` and add the following lines:

```
#
# This file is the mystartup recipe.
#

SUMMARY = "Simple mystartup application"
SECTION = "PETALINUX/apps"
LICENSE = "MIT"
LIC_FILES_CHKSUM =
"file://${COMMON_LICENSE_DIR}/MIT;md5=0835ade698e0bcf8506ecda2f7b4f302"

SRC_URI = "file://mystartup.c \
          file://Makefile \
          file://mystartup.sh \
          "
INITSCRIPT_NAME = "mystartup"
INITSCRIPT_PARAMS = "defaults"

S = "${WORKDIR}"

inherit update-rc.d

do_compile() {
    oe_runmake
}

do_install() {
    install -d ${D}${bindir}
    install -m 0755 mystartup ${D}${bindir}
    install -d ${D}${sysconfdir}/init.d/
    install -m 0755 mystartup.sh ${D}${sysconfdir}/init.d/mystartup
}
```

---

## Debugging the Linux Kernel in QEMU

This section describes how to debug the Linux Kernel inside QEMU, using the GDB debugger. Note that this function is only tested with Zynq family devices platform.

### Prerequisites

This section assumes that you have built PetaLinux system image. Refer to section [Build System Image](#) for more information.

## Steps to Debug the Linux Kernel in QEMU

1. Launch QEMU with the currently built Linux by running the following command:

```
$ petalinux-boot --qemu --kernel
```

2. Watch the qemu console, you should see the details of the QEMU command, get the GDB TCP port from `-gdb tcp:<TCP_PORT>`.

3. Open another command console (ensuring the PetaLinux settings script has been sourced), and change to the Linux directory:

```
$ cd "<plnx-proj-root>/images/linux"
```

4. Start GDB on the vmlinux kernel image in command mode:

```
$ petalinux-util --gdb vmlinux
```

You should see the gdb prompt. For example:

```
GNU gdb (Sourcery CodeBench Lite 2013.11-53) 7.6.50.20130726-cvs
GNU gdb (Linaro GDB 2016.08) 7.11.1.20160801-git
Copyright (C) 2016 Free Software Foundation, Inc.
License GPLv3+: GNU GPL version 3 or later <http://gnu.org/licenses/gpl.html>
This is free software: you are free to change and redistribute it.
There is NO WARRANTY, to the extent permitted by law. Type "show copying"
and "show warranty" for details.
This GDB was configured as "--host=x86_64-unknown-linux-gnu
--target=aarch64-linux-gnu".
Type "show configuration" for configuration details.
For bug reporting instructions, please see:
<http://www.gnu.org/software/gdb/bugs/>.
Find the GDB manual and other documentation resources online at:
<http://www.gnu.org/software/gdb/documentation/>.
For help, type "help".
Type "apropos word" to search for commands related to "word"...
Reading symbols from vmlinux...done.
```

5. Attach to the QEMU target in GDB by running the following GDB command:

```
(gdb) target remote :9000
```

6. To let QEMU continue execution:

```
(gdb) continue
```

7. You can use `Ctrl+C` to interrupt the kernel and get back the GDB prompt.
8. You can set break points and run other GDB commands to debug the kernel.

**CAUTION!** *If another process is using port 9000, petalinux-boot will attempt to use a different port. Look at the output of petalinux-boot to determine what port was used. In the following example port 9001 was used.*

*INFO: qemu-system-arm ... -gdb tcp::9001 ...*

**TIP:** It may be helpful to enable kernel debugging in the kernel configuration menu (`petalinux-config --kernel > Kernel hacking > Kernel debugging`), so that kernel debug symbols are present in the image.

## Troubleshooting

This section describes some common issues you may experience while debugging the Linux kernel in QEMU.

Table 1-16: Debugging the Linux Kernel in QEMU Troubleshooting

Problem / Error Message	Description and Solution
(gdb) target remote W.X.Y.Z:9000:9000: Connection refused.	<p><b>Problem Description:</b> GDB failed to attach the QEMU target. This is most likely because the port 9000 is not the one QEMU is using.</p> <p><b>Solution:</b></p> <ul style="list-style-type: none"> <li>• Check your QEMU console to make sure QEMU is running.</li> <li>• Watch the Linux host command line console. It will show the full QEMU commands, you should be able to see which port is used by QEMU.</li> </ul>

## Debugging Applications with TCF Agent

This section talks about debugging user applications with the Eclipse TCF (Target Communication Framework) Agent. This section describes the basic debugging procedure for Zynq user application myapp.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- Working knowledge with Xilinx Software Development Kit (XSDK) tool.
- The Vivado Tools Working Environment is properly set. Refer to section [PetaLinux Working Environment Setup](#).
- You have created a user application and built the system image including the selected user application. Refer to section [Building User Applications](#).

### Preparing the build system for debugging

1. Change to the project directory:

```
$ cd <plnx-proj-root>
```

2. Run `petalinux-config -c rootfs` on the command console:

```
$ petalinux-config -c rootfs
```

3. Scroll down the linux/rootfs Configuration menu to Filesystem Packages, followed by the base sub-menu:

```
[ ] Advanced Package Selection
[*] base-system-default
base ---->
baseutils ---->
benchmark ---->
console ---->
devel ---->
doc ---->
kernel -->
libs ---->
misc ---->
multimedia -->
net -->
network -->
optional -->
x -->
x11 -->
```

4. Select base ----> submenu, and then click into misc ----> submenu:

```
base ---->
baseutils ---->
benchmark ---->
console ---->
devel ---->
fonts ---->
kernel -->
libs ---->
misc ---->
multimedia -->
net -->
network -->
optional -->
x -->
x11 -->
```

5. Packages are in alphabetical order. Navigate to the letter 't', as shown below:

```
tbb -->
tcf-agent -->
tiff -->
util-macros -->
v4l-utils -->
videoproto -->
vte -->
x264 -->
xauth -->
xcb-util-image -->
xcb-util-keysyms -->
xcb-util-renderutil -->
xcb-util-wm -->
xcmiscproto -->
xdpyinfo -->
```

6. Ensure that `tcf-agent` is enabled.

```
[*] tcf-agent
[ ] tcf-agent-dev
[ ] tcf-agent-dbg
```

7. Select `console/network` ---> submenu, and then click into `dropbear` ---> submenu. Ensure "dropbear-openssh-sftp-server" is enabled.

```
[*] dropbear-openssh-sftp-server
```

8. Exit the menu and select `<Yes>` to save the configuration.
9. Rebuild the target system image including `myapp`. Refer to section [Build System Image](#).

## Performing a Debug Session

1. Boot your board (or QEMU) with the new image.
2. The boot log should indicate that `tcf-agent` has started. The following message should be seen:

```
Starting tcf-agent: OK
```

3. Launch Xilinx SDK, and create a workspace.
4. Add a Hardware Platform Specification by selecting `File > New > Project`.
5. In the pop-up window select `Xilinx > Hardware Platform Specification`.
6. Give the Hardware Project a name. For example, `ZC702`
7. Locate the `system.hdf` for your target hardware. This can be found in `<plnx-proj-root>/project-spec/hw-description/system.hdf`.
8. Open the Debug Launch Configuration window by selecting `Run > Debug Configurations`.
9. Create a new Xilinx C/C++ application (System Debugger) and launch configuration:

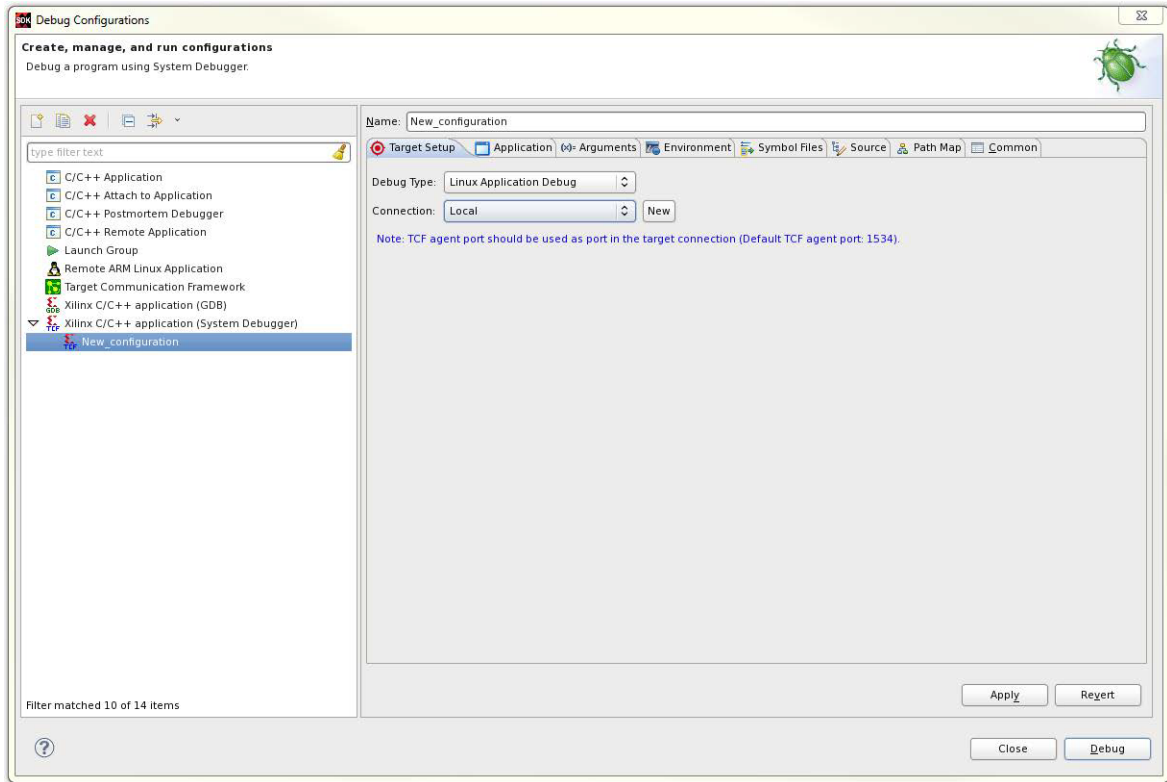

Figure 1-1: XSDK Debug Configurations

10. The Debug Type should be set to Linux Application Debug.
11. Select the New option to enter the Connection details.

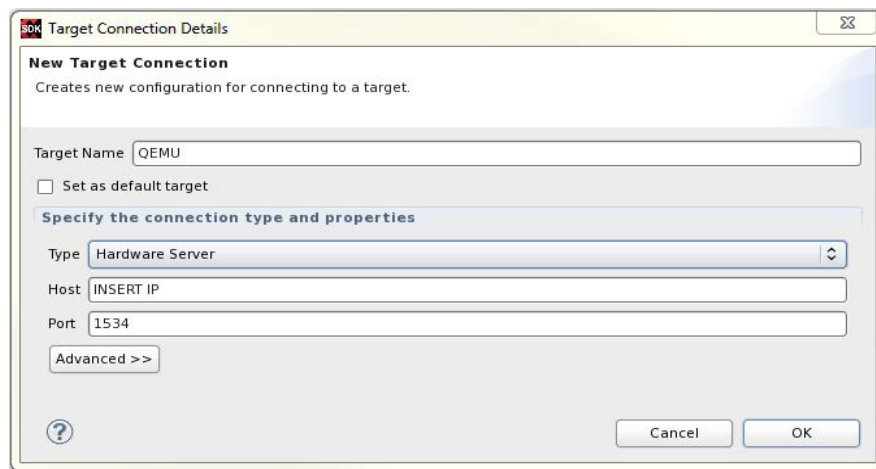

Figure 1-2: XSDK Debug New Target Configuration

12. Give the Target Connection a name, and specify the Host (IP address for the target).
13. Set the port of tcf-agent and select OK.

**IMPORTANT:** If debugging on QEMU, refer to Appendix D QEMU Virtual Networking Modes for information regarding IP and port redirection when testing in non-root (default) or root mode. For example, if testing in non-root mode, you will need to use localhost as the target IP in the subsequent steps.

14. Switch to the Application Tab.

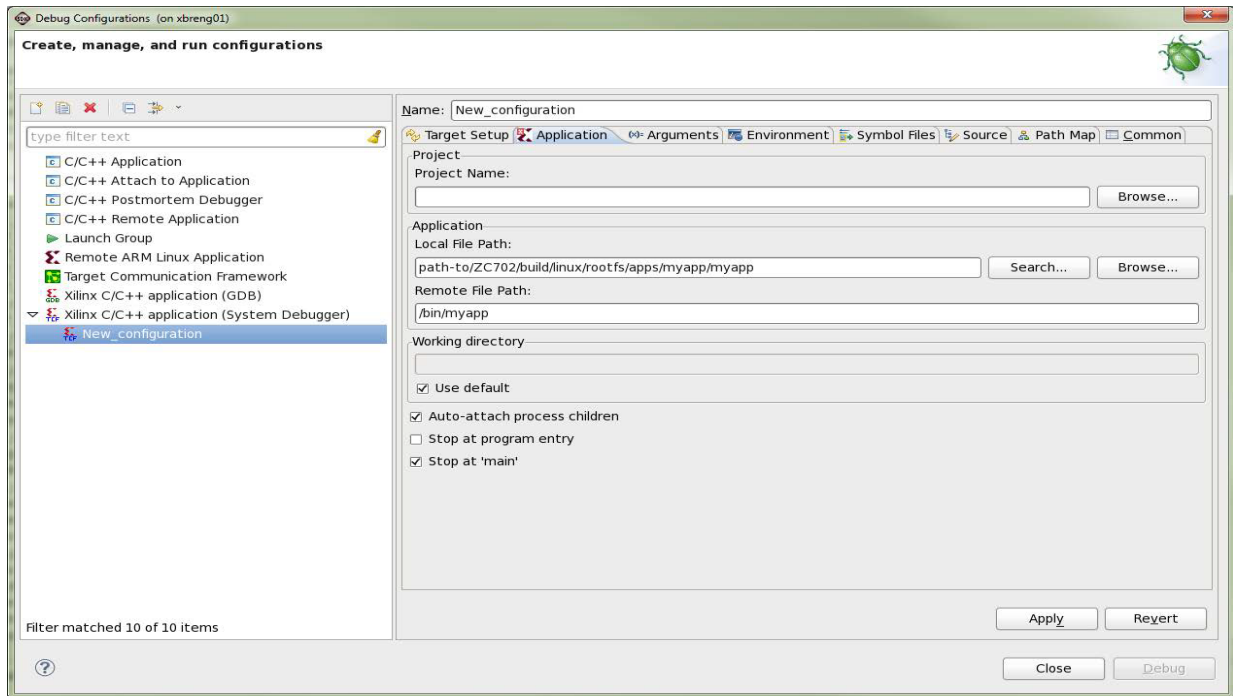

Figure 1-3: XSDK Debug Configurations

15. Enter the Local File Path to your compiled application in the project directory. For example,  
`<TMPDIR>/{ARCH}--xilinx-linux-gnueabi/myapp/1.0-r0/image/usr/bin/.`

**Note:** While creating the app, you need to add `RM_WORK_EXCLUDE == "myapp"`, otherwise the images will not be available for debugging.

16. The Remote File Path on the target file system should be the location where the application can be found. For example, `/usr/bin/myapp`.

17. Select Debug to Apply the configuration and begin the Debug session. (If asked to switch to Debug Perspective, accept).

18. Standard XSDK debug flow is ready to start:

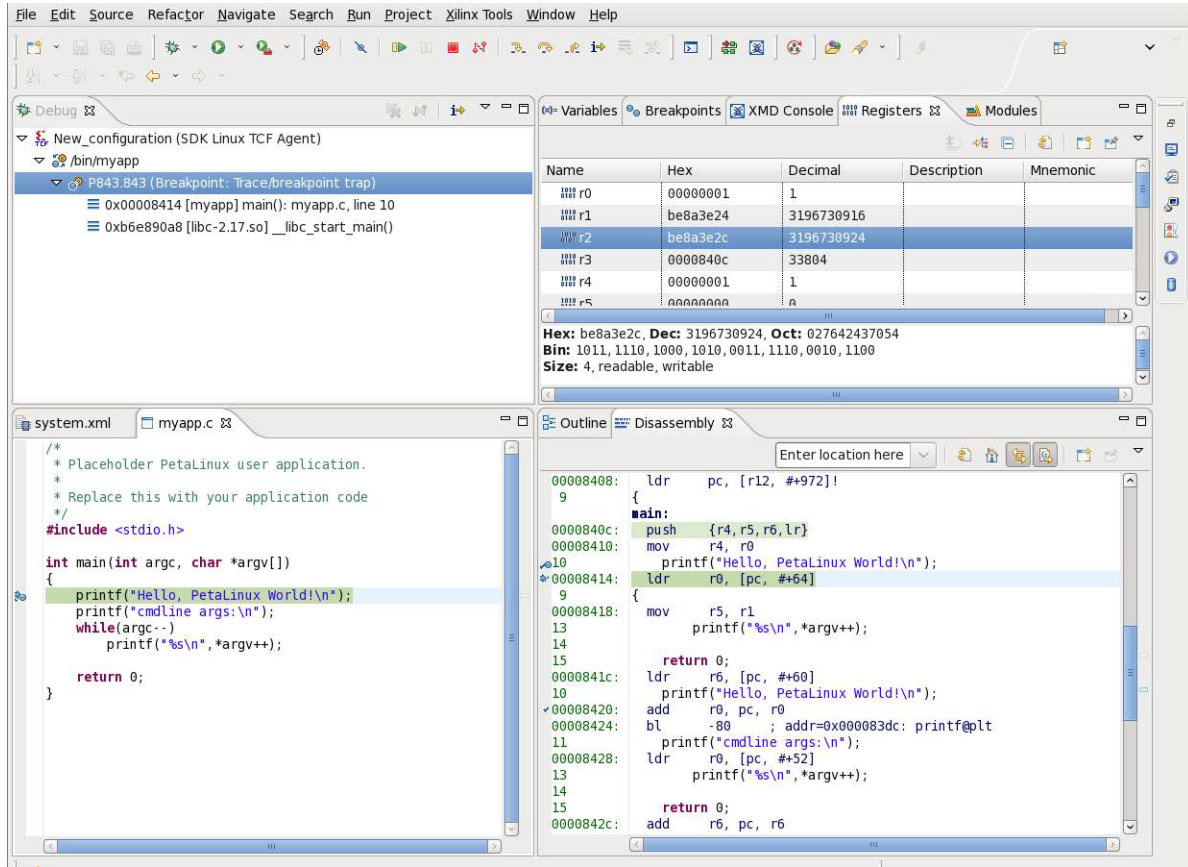

Figure 1-4: XSDK Debug

**TIP:** To analyze the code and debug you can use the following short keys:

- Step Into (F5)
- Step Over (F6)
- Step Return (F7)
- Resume (F8)

# Debugging Zynq UltraScale+ MPSoC Applications with GDB

PetaLinux supports debugging Zynq UltraScale+ MPSoC user applications with GDB. This section describes the basic debugging procedure.

## Prerequisites

This section assumes that the following prerequisites have been satisfied:

- The Vivado Tools Working Environment is properly set. Refer to section [PetaLinux Working Environment Setup](#).
- You have created a user application and built the system image including the selected user application. Refer to section [Building User Applications](#).

## Preparing the build system for debugging

1. Change to the project directory:

```
$ cd <plnx-proj-root>
```

2. Run `petalinux-config -c rootfs` on the command console:

```
$ petalinux-config -c rootfs
```

3. Scroll down the linux/rootfs Configuration menu to Debugging:

```
Filesystem Packages ---->
Libs --->
Apps --->
Modules ---->
PetaLinux RootFS Settings ---->
```

4. Select Apps -->myapp -->

```
[ ] myapp
[X] myapp-dbg
[ ] myapp-dev
```

Select `myapp-dbg`. Exit the `myapp` sub-menu.

5. Exit the App sub-menu, and select the Filesystem Packages, followed by the base sub-menu:

```
misc
```

6. Select the `gdb` sub-menu option, and ensure `gdbserver` is enabled:

```
selecting_gdb server
```

7. Exit the menu and select `<Yes>` to save the configuration.

8. Rebuild the target system image. Refer to section [Build System Image](#).

## Performing a Debug Session

1. Boot your board (or QEMU) with the new image created above.
2. Run `gdbserver` with the user application on the target system console (set to listening on port 1534):

```
root@plnx_aarch64:~# gdbserver host:1534 /usr/bin/myapp
Process /bin/myapp created; pid = 73
Listening on port 1534
```

1534 is the `gdbserver` port - it can be any unused port number

3. On the workstation, navigate to the compiled user application's directory:

```
$ cd <plnx-proj-root>/build/linux/rootfs/apps/myapp
```

4. Run GDB client.

```
$ petalinux-util --gdb myapp
```

5. The GDB console will start:

```
...
GNU gdb (crosstool-NG 1.18.0) 7.6.0.20130721-cvs
...
(gdb)
```

6. In the GDB console, connect to the target machine using the command:
  - a. Use the IP address of the target system, for example: 192.168.0.10. If you are not sure about the IP address, run `ifconfig` on the target console to check.
  - b. Use the port 1534. If you select a different `gdbserver` port number in the earlier step, use that value instead.

---

**IMPORTANT:** *If debugging on QEMU, refer to the QEMU Virtual Networking Modes for information regarding IP and port redirection when testing in non-root (default) or root mode. For example, if testing in non-root mode, you will need to use localhost as the target IP in the subsequent steps.*

---

```
(gdb) target remote 192.168.0.10:1534
```

The GDB console will attach to the remote target. Gdbserver on the target console will display the following confirmation, where the host IP is displayed:

```
Remote Debugging from host 192.168.0.9
```

7. Before starting the execution of the program, create some breakpoints. Using the GDB console you can create breakpoints throughout your code using function names and line numbers. For example, create a breakpoint for the `main` function:

```
(gdb) break main
Breakpoint 1 at 0x10000444: file myapp.c, line 10.
```

- Run the program by executing the `continue` command in the GDB console. GDB will begin the execution of the program.

```
(gdb) continue
Continuing.
Breakpoint 1, main (argc=1, argv=0xbffffe64) at myapp.c:10
10         printf("Hello, PetaLinux World!\n");
```

- To print out a listing of the code at current program location, use the `list` command.

```
(gdb) list
5 */
6 #include <stdio.h>
7
8 int main(int argc, char *argv[])
9 {
10 printf("Hello, PetaLinux World!\n");
11 printf("cmdline args:\n");
12 while(argc--)
13 printf("%s\n", *argv++);
14
```

- Try the `step`, `next` and `continue` commands. Breakpoints can be set and removed using the `break` command. More information on the commands can be obtained using the GDB console `help` command.
- When the program finishes, the GDB server application on the target system will exit. Here is an example of messages shown on the console:

```
Hello, PetaLinux World!
cmdline args:
/usr/bin/myapp
Child exited with status 0
GDBserver exiting
root@plnx_aarch64:~#
```

---

**TIP:** A `.gdbinit` file will be automatically created, to setup paths to libraries. You may add your own GDB initialization commands at the end of this file.

---

## Going Further With GDB

Visit [www.gnu.org](http://www.gnu.org), for more information on general usage of GDB, refer to the GDB project documentation:

## Troubleshooting

This section describes some common issues you may experience while debugging applications with GDB.

Table 1-17: Debugging Zynq Ultrascale+ MPSoC Applications with GDB Troubleshooting

Problem / Error Message	Description and Solution
<p>GDB error message: &lt;IP Address&gt;:&lt;port&gt;: Connection refused. GDB cannot connect to the target board using &lt;IP&gt;: &lt;port&gt;</p>	<p><b>Problem Description:</b> This error message indicates that the GDB client failed to connect to the GDB server.</p> <p><b>Solution:</b></p> <ul style="list-style-type: none"> <li>• Check whether the <code>gdbserver</code> is running on the target system.</li> <li>• Check whether there is another GDB client already connected to the GDB server. This can be done by looking at the target console. If you can see:  <pre>Remote Debugging from host &lt;IP&gt;</pre> It means there is another GDB client connecting to the server.</li> <li>• Check whether the IP address and the port are correctly set.</li> </ul>

## Configuring Out-of-tree Build

PetaLinux has the ability to automatically download up-to-date kernel/u-boot source code from a `git` repository. This section describes how this features works and how it can be used in system-level menu config. It describes two ways of doing the out-of-tree builds.

### Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.
- Internet connection with `git` access is available.

### Steps to Configure out-of-tree Build

Steps to configure UBOOT/Kernel out-of-tree build:

1. Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

2. Launch the top level system configuration menu.

```
$ petalinux-config
```

3. Select "linux Components Selection --->" sub-menu.
  - For kernel, select "linux-kernel () --->" and then select remote
    - ( ) linux-xlnx
    - ( ) ext-local-src
    - (X) remote
  - For U-boot, select " u-boot () --->" and then select remote
    - ( ) u-boot-plnx
    - (X) remote
    - ( )ext-local-src
4. For kernel, select "Remote linux-kernel settings --->", select Remote linux-kernel git URL and enter git URL for linux-kernel.

For example: `git://github.com/Xilinx/linux-xlnx.git`

For u-boot, select "Remote u-boot settings --->", select Remote u-boot git URL and enter git URL for u-boot. For example:

`git://github.com/Xilinx/u-boot-xlnx.git`

**Note:** Only `git://` has to be entered.

Set a git tag as "Remote git TAG/commit ID".

You have to set any of the following values to this setting, otherwise an error message appears.

1 - To point to HEAD of repo

`${AUTOREV}`

2 - To point to any tag

`petalinux-v2016.4-final`

3 - To point to any commit id:

`commit id sha key`

5. Exit the menu, and save your settings.

## Using External Kernel and U-boot With PetaLinux

PetaLinux includes kernel source and u-boot source. However, you can build your own kernel and u-boot with PetaLinux.

Petalinux supports local sources for kernel, Uboot and ATF

For external sources create a directory <plnx-proj-root>/components/ext\_sources/

1. Copy the kernel source directory to

```
<plnx-proj-root>/components/ext_sources/<MY-KERNEL>
```

2. Copy the u-boot source directory to

```
<plnx-proj-root>/components/ext_sources/<MY-U-BOOT>
```

3. Run petalinux-config, and go into "linux Components Selection --->" sub-menu,

- For kernel, select "linux-kernel () --->" and then select ext-local-src

```
( ) linux-xlnx
(X) ext-local-src
( ) remote
```

- For U-boot, select " u-boot () --->" and then select ext-local-src

```
( ) u-boot-plnx
( ) remote
(X) ext-local-src
```

4. For kernel, select "External linux-kernel local source settings ---> "

5. Enter the path:

```
${TOPDIR}/../components/ext_sources/<MY-KERNEL>
```

6. For uboot, select "External u-boot local source settings --->". Enter the path:

```
${TOPDIR}/../components/ext_sources/<MY-U-BOOT>
${TOPDIR} --> is the yocto variable pointing to <plnx-proj-root>/build directory
```

You can give an absolute path for the source, but you must make sure you change the path while using the BSP with the source. It is your responsibility to change the source path. The sources can be placed outside the project as well.

**Note:** When creating a BSP with external sources in project, it is your responsibility to copy the sources into the project and do the packing. Please refer to [BSP Packaging](#) section for more details.

## Troubleshooting

This section describes some common issues you may experience while configuring out-of-tree build.

Table 1-18: Configuring Out-of-Tree Build Troubleshooting

Problem / Error Message	
fatal: The remote end hung up unexpectedly ERROR: Failed to get linux-kernel	<p><b>Problem Description:</b> This error message indicates that system is unable to download the source code (Kernel/UBOOT) using remote git URL and hence can not proceed with petalinux-build.</p> <p><b>Solution:</b></p> <ul style="list-style-type: none"> <li>• Check whether entered remote git URL is proper or not.</li> <li>• If above solution does not solve the problem, Cleanup the build with the following command: \$ petalinux-build -x mrproper Above command will remove following directories. <ul style="list-style-type: none"> <li>◦ &lt;plnx-proj-root&gt;/images/</li> <li>◦ &lt;plnx-proj-root&gt;/build/</li> </ul> </li> </ul> <p>Re build the system image. Refer to section <a href="#">Build System Image</a>.</p>

---

## Devicetree Configuration

This section describes which files are safe to modify for the device tree configuration and how to add new information into the device tree.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

### Configuring Devicetree

PetaLinux device tree configuration is associated with following config files that are located at <plnx-projroot>/components/plnx\_workspace/device-tree-generation/ and <plnx-proj-root>/project-spec/meta-user/recipes-dt/device-tree/.

- pcw.dtsi
- plnx\_aarch64-system.dts
- system.dts
- system-conf.dtsi

- `system-top.dts`
- `zynqmp-clk.dtsi`, for Zynq UltraScale+ MPSoC
- `zynqmp.dtsi`, for Zynq UltraScale+ MPSoC

**CAUTION!** All the above mentioned `dtsi` files are generated by the tool. Editing any of these files is not recommended.

The `<plnx-projroot>/project-spec/meta-user/recipes-dt/device-tree` holds the device-tree `bbappend` and files directory. The files directory holds the `system-top.dts` which can be modified.

For more details on device-tree files, refer to [Appendix A, PetaLinux Project Structure](#).

**CAUTION!** `DTSI` files listed above `*.dtsi` are automatically generated; user is not supposed to edit these files.

If you wish to add information, like the Ethernet PHY information, this should be included in the `system-top.dts` file. In this case, device tree should include the information relevant for your specific platform as information (here, Ethernet PHY information) is board level and board specific.

**Note:** The need for this manual interaction is because some information is "board level" and the tools do not have a way of predicting what should be here. Refer to the Linux kernel Device Tree bindings documents (Documentation/devicetree/bindings from the root of the kernel source) for the details of bindings of each device.

An example of a well-formed Device-tree node for the `system-top.dts` is below.

```
/dts-v1/;
/include/ "system-conf.dtsi"
/ {
};
&gem0 {
    phy-handle = <&phy0>;
    ps7_ethernet_0_mdio: mdio {
        phy0: phy@7 {
            compatible = "marvell,88e1116r";
            device_type = "ethernet-phy";
            reg = <7>;
        };
    };
};
```

**IMPORTANT:** Ensure that the device tree node name, MDIO address, and compatible strings correspond to the naming conventions used in your specific system.

You can add the custom `dtsi` files. All modified or new `dtsi` files should be placed in `<plnx_proj_root>/project-spec/meta-user/recipes-dt/device-tree`.

You can add your custom dtsi files. All modifications or new dtsi files should be placed in `<plnx_proj_root>/project-spec/meta-user/recipes-dt/device-tree`

The following example demonstrates adding `sample-user-1.dtsi` and `sample-user-2.dtsi` file:

```
SRC_URI_append = "\
    file://system-top.dts \
    file://sample-user-1.dtsi \
    file://sample-user-2.dtsi \
"
FILESEXTRAPATHS_prepend := "${THISDIR}/files:"
do_compile_prepend () {
    install -m 644 ${WORKDIR}/sample-user-1.dtsi ${dts_dir}/
    install -m 644 ${WORKDIR}/sample-user-2.dtsi ${dts_dir}/
}
changes in system-top.dts
/dts-v1/;
/include/ "system-conf.dtsi"
/include/ "sample-user-1.dtsi.dtsi"
/include/ "sample-user-2.dtsi.dtsi"
```

It is not recommended to change anything in `<plnx-proj-root>/components/plnx_workspace/device-tree-generation/`

All the changes have to be made in meta-user only. For example, if you want to change anything, you can do in meta-user by rewriting the entire node with your changes in meta-user layer.

## U-Boot Configuration

This section describes which files are safe to modify for the U-Boot configuration and discusses about the U-Boot `CONFIG_` options/settings.

### Prerequisites

This section assumes that you have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.

## Configuring U-Boot

Universal Bootloader (U-Boot) Configuration is usually done using C pre-processor defines:

- Configuration `_OPTIONS_`:

These are selectable by the user and have names beginning with "CONFIG\_".

- Configuration `_SETTINGS_`:

These depend on the hardware etc. They have names beginning with "CONFIG\_SYS\_".

**TIP:** Detailed explanation on `CONFIG_` options/settings documentation and README on U-Boot can be found at [Denz U-Boot Guide](#).

PetaLinux u-boot configuration is associated with `config.mk` and `platform-auto.h` configuration files which are located at `<plnxproj_root>/project-spec/meta-plnx-generated/recipes-bsp/u-boot/configs` and `platform-top.h` located at `<plnxproj_root>/project-spec/meta-user/recipes-bsp/u-boot/files/`.

For setting u-boot environment variables, edit `CONFIG_EXTRA_ENV_SETTINGS` variable in `platform-auto.h`. Note that `platform-auto.h` is regenerated each time user "petalinux-config" is run.

**CAUTION!** `config.mk` and `platform-auto.h` files are automatically generated; do not edit these files.

PetaLinux does not currently automate U-Boot configuration with respect to `CONFIG_` options/settings. The user can add these `CONFIG_` options/settings into `platform-top.h` file.

Steps to add `CONFIG_` option (For example, `CONFIG_CMD_MEMTEST`) to `platform-top.h`:

- Change into the root directory of your PetaLinux project.

```
$ cd <plnx-proj-root>
```

- Open the file `platform-top.h`

```
$ vi project-spec/meta-user/recipes-bsp/u-boot/files/platform-top.h
```

- If you want to add `CONFIG_CMD_MEMTEST` option, add the following line to the file. Save the changes.

```
#define CONFIG_CMD_MEMTEST
```

**TIP:** Defining `CONFIG_CMD_MEMTEST` enables the Monitor Command "mtest", which is used for simple RAM test.

- Build the U-Boot image.

```
$ petalinux-build -c u-boot
```

- Generate `BOOT.BIN` using the following command.

```
$ petalinux-package --boot --fsbl <FSBL image> --fpga <FPGA bitstream> --u-boot
```

- Boot the image either on hardware or QEMU and stop at U-Boot stage.
- Enter the "mtest" command in the U-Boot console as follows:

```
U-Boot-PetaLinux> mtest
```

- Output on the U-Boot console should be similar to the following:

```
Testing 00000000 ... 00001000:  
Pattern 00000000 Writing... Reading... Iteration: 20369
```

**IMPORTANT:** If `CONFIG_CMD_MEMTEST` is not defined, output on U-Boot console will be as follows:

```
U-Boot-PetaLinux> mtest  
Unknown command 'mtest' - try 'help'
```

## Kernel and U-boot Configuration flow

Previously, the tool maintained full configuration for kernel and u-boot under `<plnx-proj-root>/subsystems/linux/kernel` and `<plnx-proj-root>/subsystems/linux/u-boot`

Now, with the new tool, the configuration approach has been changed. Yocto provides methodology of configuration fragments (.cfg). You can apply this configuration fragment on the top of defconfig from main line. With this, you need not maintain full config for your projects.

The PetaLinux tool for Kernel and u-boot takes defconfig from the main line and the configuration fragments with respect to HDF, bsp and user are applied on top of it.

$$\text{defconfig} + [\text{HDF cfg}] + [\text{bsp cfg}] + [\text{user cfg's}] = \text{full config (.config)} \quad \text{Equation 1-1}$$

For example: You can apply your own CFG's by adding the following line in corresponding bbappend:

```
SRC_URI_append = " myconfig.cfg"
```

Custom full defconfig: You can provide your own custom config.

For example: For kernel

1. Copy the config file to  
`<plnx-proj-root>/project-spec/meta-user/recipes-kernel/linux/linux-xlnx/`
2. Rename the file to defconfig in  
`project-spec/meta-user/recipes-kernel/linux/linux-xlnx/`
3. Edit  
`<plnx-proj-root>/project-spec/meta-user/recipes-kernel/linux/linux-xlnx_%.bbappend`

4. Add a new line

```
SRC_URI_append = "    file://defconfig"
```

**Note:** Any variable with `_append` should have space in the beginning. Yocto works with file name extensions, hence it is mandatory to provide a configuration fragment with `.cfg` extension and a config file with `defconfig`.

# Yocto Features

This chapter gives all the information regarding the various features provided by Yocto.

---

## Adding Patches to Source Repo

If the sources of a component is a git repo, you can apply patches on top of the repo.

An example to add patches for u-boot and to apply `mypatch.patch` is given below:

1. Copy the `mypatch.patch` to  
`<plnx-proj-root>/project-spec/meta-user/recipes-bsp/u-boot/files`  
`/`
2. Open  
`<plnx-proj-root>/project-spec/meta-user/recipes-bsp/u-boot/u-boot-xlnx_%.bbappend` and add the following line:

```
SRC_URI_append = " file://mypatch.patch"
```

If there is no `bbappend` for a utility, you have to create `bbappend` for that utility on the similar lines. An example for sample utility with `mypatch.patch` is shown below:

- a. Create directory  
`<plnx-proj-root>/project-spec/meta-user/recipes-apps/sampleutility/files/`
- b. Copy `mypatch.patch` to  
`<plnx-proj-root>/project-spec/meta-user/recipes-apps/sampleutility/files/`
- c. Open  
`<plnx-proj-root>/project-spec/meta-user/recipes-apps/sampleutility/sampleutility_%.bbappend` and add the following line:

```
FILESEXTRAPATHS_prepend := "${THISDIR}/files:"
```

Yocto will apply the patch on the fetched git repo.

## Accessing BitBake in a Project

BitBake is available only in the bash shell.

### Steps to get the BitBake utility for Zynq Ultrascale+ MPSoC:

1. You should run `petalinux-config` or `petalinux-config --oldconfig` at least once after creating the project, so that the required environment is setup.

2. Source the PetaLinux tools script:

```
source /opt/pkg/petalinux/settings.sh
```

3. Source the Yocto e-SDK:

```
source /opt/pkg/petalinux/components/yocto/source/aarch64/environment
-setup-aarch64-xilinx-linux
```

4. Source the environment setup script:

```
source
/opt/pkg/petalinux/components/yocto/source/aarch64/layers/poky/oe-init-build-env
```

5. After the above step, you will be redirected to the build directory. Stay in the build directory to run bitbake.

6. Export XSCT:

```
export PATH=/opt/pkg/petalinux/tools/hsm/bin:$PATH
```

7. Parse PETALINUX variable to recipes:

```
export BB_ENV_EXTRAWHITE="$BB_ENV_EXTRAWHITE PETALINUX"
```

8. To test if the bitbake is available, run:

```
bitbake fsbl -c cleansstate
bitbake fsbl
```

The generated images will be placed in the deploy directory. You have to copy the generated images into `<plnx-proj-root>/images/linux` directory to work with the other commands.

## Adding a Recipe from the Layers in SDK which are not in petalinux-image.bb

The rootfs menuconfig is populated based on petalinux-image. The petalinux-image target is supported by Xilinx.

An example to add alsa-utils is shown below:

1. The recipes can be found in yocto e-SDK:  
layers/poky/meta/recipes-multimedia/alsa/
2. Open  
<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend and add the following line:

```
IMAGE_INSTALL_append = " alsa-utils"
```

3. Run `petalinux-config -c rootfs`

Select "Filesystem Packages -->"

Select "console -->"

Select "utils -->"

and then select "alsa-utils"

Enable it, save and exit

4. Run `petalinux-build`

**Note:** It is your responsibility to add the recipes in the layers available in petalinux tools, apart from petalinux-image.

**Note:** Whenever "\_append" is used, there should exist an initial space after = "".

## Adding Package Group

One of the best approaches for customizing images is to create a custom package group, that will be used to build the images. Some of the package group recipe is shipped with the PetaLinux tools.

For example:

```
$PETALINUX/components/yocto/source/aarch64/layers/meta-petalinux/recipes-core/packagegroups/packagegroup-petalinux-x11.bb
```

We can add custom package group, for example, an ALSA package group would be:

```
DESCRIPTION = "PetaLinux ASLA supported Packages"
```

```
inherit packagegroup
```

```

ALSA_PACKAGES = " \
    alsa-lib \
    alsa-plugins \
    alsa-tools \
    alsa-utils \
    alsa-utils-scripts \
    pulseaudio \
"
RDEPENDS_${PN}_append_zynqmp += " \
    ${ALSA_PACKAGES} \
"

```

This can be added to

```
<plnx-proj-root>/meta-user/recipes-core/packagegroups/packagegroup-petalinux-alsa.bb
```

Add this package group in

```
<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/petalinux-image.bbappend to reflect in menuconfig.
```

## Shared sstate-cache

Yocto e-SDK contains minimal shared sstate-cache. Xilinx hosts the full petalinux-image shared sstate-cache at <http://petalinux.xilinx.com/sswreleases/rel-v2016.4/<architecture>/>.

During petalinux-build, bitbake will search for sstate cache in the petalinux tool, that is the minimal set. If the sstate cache is not found in this location, bitbake then searches for the same in [www.xilinx.com](http://www.xilinx.com). Yet, if the sstate cache is not found, bitbake will build from scratch.

# PetaLinux Project Structure

This section provides a brief introduction to the file and directory structure of a PetaLinux project. A PetaLinux project supports development of a single Linux system development at a time. A built Linux system is composed of the following components:

- device tree
- first stage bootloader (optional)
- u-boot
- Linux kernel
- rootfs. rootfs is composed of the following components:
  - Prebuilt packages
  - Linux user applications (optional)
  - User modules (optional)

A PetaLinux project directory contains configuration files of the project, the Linux subsystem, and the components of the subsystem. The `petalinux-build` command builds the project with those configuration files. Users can run `petalinux-config` to modify them. Here is an example of a PetaLinux project:

```
<plnx-proj-root>
  -components
    -plnx_workspace
      -device-tree-generation
        -system.dts
        -zynqmp-clk.dtsi
        -pcw.dtsi
        -plnx_aarch64-system.dts
        -system-conf.dtsi
        -system-top.dts
        -zynqmp.dtsi
      -fsbl
      -fsbl_bsp
      -fsbl_hwproj
      -pmu-firmware
      -pmu-firmware_bsp
      -pmu-firmware_hwproj
      -SDK.log
      -xsctlock
    -config.project
    -hardware
```

```

-pre-built
  -linux
    -etc/
    -images/
    -implementation/
-project-spec
  -attributes
  -configs/
    rootfs_config
    config
  -hw-description/
  -meta-plnx-generated/
  -meta-user/

```

Table A-1: PetaLinux Project Description

File / Directory in a PetaLinux Project	Description
"<plnx-proj-root>/ .petalinux /"	Directory to hold tools usage and WebTalk data.
"<plnx-proj-root>/config.project/"	Project configuration file.
"<plnx-proj-root>/project-spec"	Project specification of the project.
"<plnx-proj-root>/project-spec/hw-description"	Hardware description imported from Vivado.
"<plnx-proj-root>/project-spec/configs"	Configuration files of top level config and rootfs config
"<plnx-proj-root>/project-spec/configs/config"	Configuration file used store user settings
"<plnx-proj-root>/project-spec/configs/rootfs_config"	Configuration file used for root filesystem.
"<plnx-proj-root>/components/plnx_workspace/device-tree-generation/"	<p>Device tree files used to build device tree. The following files are auto generated by petalinux-config:</p> <ul style="list-style-type: none"> <li>• skeleton.dtsi (Zynq-7000 only)</li> <li>• zynq-7000.dtsi (Zynq-7000 only)</li> <li>• zynqmp.dtsi (Zynq UltraScale+ MPSoC only)</li> <li>• pcw.dtsi (Zynq-7000 and Zynq UltraScale+MPSoC only)</li> <li>• pl.dtsi</li> <li>• system-conf.dtsi</li> </ul> <p>It is not recommended to edit these files, as these files are regenerated by the tools.</p>
"<plnx-proj-root>/project-spec/meta-user/recipes-dt/device-tree/files/"	system-top.dts is not modified by any PetaLinux tools. This file is safe to use with revision control systems. In addition, you can add your own DTSI files to this directory. You have to edit the bbappend by adding your dtsi file.

Table A-1: PetaLinux Project Description (Cont'd)

File / Directory in a PetaLinux Project	Description
"<plnx-projroot>/project-spec/meta-plnx-generated/recipes-bsp/u-boot/configs"	U-Boot PetaLinux configuration files. The following files are auto generated by petalinux-config: <ul style="list-style-type: none"> <li>• config.mk for MicroBlaze only</li> <li>• platform-auto.h</li> <li>• config.cfg</li> </ul> platform-top.h will not be modified by any PetaLinux tools. When U-Boot builds, these files are copied into U-Boot build directory build/linux/u-boot/src/<U_BOOT_SRC>/ as follows: <ul style="list-style-type: none"> <li>• config is the u-boot kconfig file.</li> <li>• config.mk is copied to board/xilinx/microblaze-generic/ for MicroBlaze.</li> </ul>
<plnx-projroot>/project-spec/meta-user/recipes-bsp/u-boot/files/platform-top.h	<ul style="list-style-type: none"> <li>• platform-auto.h and platform-top.h is copied to include/configs/ directory.</li> </ul>
"<plnx-proj-root>/components/"	Directory for embeddedSW workspace and place to hold external sources while packing BSP. You can also manually copy components into this directory. Here is the rule to place a external component: "<plnx-proj-root>/components/ext_source/<COMPONENT>"

When the project is built, two directories will be auto generated:

- "<plnx-proj-root>/build" for the files generated for build.
- "<plnx-proj-root>/images" for the bootable images.
- "<plnx-proj-root>/build/tmp" for the files generated by Yocto. This directory is configurable through petalinux-config.

Here is an example:

```

<plnx-proj-root>
  -build
    -bitbake.lock
    -build.log
    -config.log
    -cache/
    -conf/
    -downloads/
    -misc/
      -config/
      -plnx-generated/
      -rootfs_config/
    -sstate-cache/
    -tmp/
  -components
    -plnx_workspace/
  -config.project
    
```

```

-hardware
-images
  -linux/
-pre-built
  -linux/
-project-spec
  -attributes
  -configs/
    -config
    -rootfs_config
  -hw-description/
  -meta-plnx-generated/
  -meta-user/
    
```

**CAUTION!** "`<plnx-proj-root>/build/`" are automatically generated. Do not manually edit files in this directory. Contents in this directory will get updated when you run `petalinux-config` or `petalinuxbuild`.

"`<plnx-proj-root>/images/`" are also automatically generated. Files in this directory will get updated when you run `petalinux-build`.

The table below is an example for Zynq Ultrascale+ MPSoC.

Table A-2: Build Directory in a PetaLinux Project

Build Directory in a PetaLinux Project	Description
" <code>&lt;plnx-proj-root&gt;/build/build.log</code> "	Logfile of the build
" <code>&lt;plnx-proj-root&gt;/build/misc/config/</code> "	Directory to hold files related to the linux subsystem build
" <code>&lt;plnx-proj-root&gt;/build/misc/rootfs_config/</code> "	Directory to hold files related to the rootfs build
" <code>&lt;plnx-projroot&gt;/build/tmp/work/plnx_aarch64-xilinx-linux/petalinux-ser-image/1.0-r0/rootfs</code> "	Target rootfs host copy
" <code>&lt;plnx-projroot&gt;/tmp/plnx_aarch64</code> "	Stage directory to hold the libs and header files required to build user apps/libs
" <code>&lt;plnx-proj-root&gt;/build/tmp/work/plnx_aarch64-xilinx-linux/linux-xlnx</code> "	Directory to hold files related to the kernel build
" <code>&lt;plnx-proj-root&gt;/build/tmp/work/plnx_aarch64-xilinx-linux/u-boot-xlnx</code> "	Directory to hold files related to the u-boot build
" <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation</code> "	Directory to hold files related to the device-tree build
" <code>&lt;plnx-projroot&gt;/components/plnx_workspace/fsbl</code> "	Directory to hold files related to the bootloader build

Table A-3: Image Directory in a PetaLinux Project

Image Directory in a PetaLinux Project	Description
"<plnx-proj-root>/images/linux/"	Directory to hold the bootable images for Linux subsystem

## Project Layers

The PetaLinux project has two following layers under <proj-plnx-root>/project-spec

1. meta-plnx-generated
2. meta-user

### ***meta-plnx-generated:***

This layer holds all bbappends and configuration fragment (cfg) for all components. All files in this layer are generated by the tool based on HDF and user configuration. The files in this layer should not be updated manually, as it is regenerated for petalinux-config and petalinux-build commands.

### ***meta-user:***

This layer is a place holder for all user-specific changes. You can add your own bbappend and configuration files in this layer.

### ***Priority of the layers:***

By default, meta-plnx-generated layer has the highest priority as the tool does not allow tainting of the system based on user-configuration. If you want to taint the system, change the priority of the meta-user to higher than meta-plnx-generated.

By default, meta-plnx-generated is at priority 6 and meta-user is at priority 4.

If you want higher priority for your changes, set meta-user priority to 7.

**Note:** Changing the meta-user priority is tainting of system. It is user responsibility for stability of system.

### **Steps to change priority of meta-user layer to 7**

1. Open <plnx-proj-plnx-root>/project-spec/meta-user/conf/layer.conf.
2. Change BBFILE\_PRIORITY\_meta-user value from 4 to 7.
3. The meta-user priority is now changed to 7.

```
BBFILE_PRIORITY_meta-user = "7"
```

# Generating First Stage Bootloader Within Project

This is optional. By default, the top level system settings are set to generate the first stage bootloader.

---

**CAUTION!** *If you do not want the PetaLinux build FSBL/FS-BOOT, then you will need to manually build it on your own. Else, your system will not boot properly.*

---

If you had disabled first stage bootloader from menuconfig previously, You can configure the project to build first stage bootloader as follows:

1. Launch top level system settings configuration menu and configure:

```
$ petalinux-config
```

- a. Click "linux Components Selection --->" sub-menu.
- b. Select "First Stage Bootloader" option.

```
[*] First Stage Bootloader
```

- c. Exit the menu and save the change.

This operation will generate the FSBL (First Stage Bootloader) source into components/bootloader/ inside your PetaLinux project root directory if it does not already exist. For Zynq® UltraScale+™ MPSoC, it will be:

```
components/plnx_workspace/fsbl/zynqmp_fsbl
```

For Zynq-7000, it will be:

```
components/plnx_workspace/fsbl/zynq_fsbl
```

For MicroBlaze, it will be:

```
components/plnx_workspace/fsbl/fs-boot
```

FSBL should be in the local project directory.

2. Launch petalinux-build to build the FSBL:

Build the FSBL when building the project:

```
$ petalinux-build
```

Build the FSBL only:

```
$ petalinux-build -c bootloader
```

The bootloader ELF file will be installed as `zynqmp_fsbl.elf` for Zynq UltraScale+ MPSoC, `zynq_fsbl.elf` for Zynq-7000 and `fs-boot.elf` for MicroBlaze in `images/linux` inside the project root directory.

---

**TIP:** `zynq_fsbl_bsp`, `zynqmp_fsbl_bsp` will be auto updated when you run `petalinux-config`.

---

## Arm Trusted Firmware (ATF)

This is for Zynq UltraScale+ MPSoC only. This is mandatory. By default, the top level system settings are set to generate the ATF.

You can set the ATF configurable options as follows:

1. Launch top level system settings configuration menu and configure:

```
$ petalinux-config
```

- a. Click into "ARM Trusted Firmware Compilation Configuration" ---> submenu.
- b. Enter your settings.
- c. Exit the menu and save the change.

2. Build the ATF when building the project:

```
$ petalinux-build
```

Build the ATF only:

```
$ petalinux-build -c arm-trusted-firmware
```

The ATF ELF file will be installed as `b131.elf` for Zynq UltraScale+ MPSoC in `images/linux` inside the project root directory.

## PMU Firmware (PMUFW)

This is for Zynq UltraScale+ MPSoC only. This is Optional. By default, the top level system settings are set to generate the PMUFW.

---

**CAUTION!** *If the user wishes not to have PetaLinux build the PMUFW, then you will need to manually build it on your own. Else, your system will not boot properly.*

---

You can configure the project to build PMUFW as follows:

1. Launch top level system settings configuration menu and configure:

```
$ petalinux-config
```

- a. Click "linux Components Selection --->" sub-menu.
- b. Select "PMU Firmware" option.

```
 [*] PMU Firmware
```

- c. Exit the menu and save the change.

2. Build the PMUFW when building the project:

```
$ petalinux-build
```

Build the PMUFW only:

```
$ petalinux-build -c pmufw
```

The PMUFW ELF file will be installed as `pmufw.elf` for Zynq UltraScale+ MPSoC in `images/linux` inside the project root directory.

## FS-Boot For MicroBlaze Platform Only

FS-Boot in PetaLinux is a first stage bootloader demo for MicroBlaze platform only. It is to demonstrate how to load images from flash to the memory and jump to it. If you want to try FS-Boot, you will need 8K Bytes BRAM at least.

FS-Boot supports Parallel flash and SPI flash in standard SPI mode only. If you are using `axi_quad_spi`, it only works with X1 mode.

In order for FS-Boot to know where in the flash should get the image, macro `CONFIG_FS_BOOT_START` needs to be defined. This is done by the PetaLinux tools. PetaLinux tools set this macro automatically from the `boot` partition settings in the `menuconfig` primary flash partition table settings. For parallel flash, it is the start address of boot partition. For SPI flash, it is the start offset of `boot` partition.

The image in the flash requires a wrapper header followed by a BIN file. FS-Boot gets the target memory location from wrapper. The wrapper needs to contain the following information:

Table B-1: Wrapper Information

Offset	Description	Value
0x0	FS-Boot bootable image magic code	0xb8b40008
0x4	BIN image size	User defined
0x100	FS-Boot bootable image target memory address	User defined. PetaLinux tools automatically calculate it from the u-boot text base address offset from the Memory Settings from the menuconfig.
0x10c	Where the BIN file start	None

FS-Boot ignores other fields in the wrapper header. PetaLinux tools generate the wrapper header to wrap around the u-boot BIN file.

# Auto Config Settings

When you run `petalinux-config`, you will see the "Auto Config Settings" sub-menu. If you click in the sub-menu, you will see the list of components which PetaLinux can do auto config based on the top level system settings. If a component is selected to enable autoconfig, when `petalinux-config` is run, its config files will be auto updated.

Table C-1: Auto Config Settings

Component in the Menu	Files impacted when autoconfig is enabled
Device tree	<ul style="list-style-type: none"> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/skeleton.dtsi</code> (Zynq-7000 only)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/zynq-7000.dtsi</code> (Zynq-7000 only)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/zynqmp.dtsi</code> (Zynq UltraScale+ MPSoC only)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/zynqmp-clk.dtsi</code> (Zynq UltraScale+ MPSoC only)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/pcw.dtsi</code> (Zynq-7000 and Zynq UltraScale+ MPSoC)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/pl.dtsi</code> (Microblaze only)</li> <li>• <code>&lt;plnx-proj-root&gt;/components/plnx_workspace/device-tree-generation/system-conf.dtsi</code></li> </ul>
kernel	<code>&lt;plnx-proj-root&gt;/project-spec/meta-plnx-generated/recipes-kernel/linux/configs/plnx_kernel.cfg</code>
u-boot	<ul style="list-style-type: none"> <li>• <code>&lt;plnx-proj-root&gt;/project-spec/meta-plnx-generated/recipesbsp/u-boot/configs/config.cfg</code></li> <li>• <code>&lt;plnx-proj-root&gt;/project-spec/meta-plnx-generated/recipesbsp/u-boot/configs/platform-auto.h</code></li> </ul>
fsbl	<code>&lt;plnx-proj-root&gt;/components/plnx_workspace/fsbl</code>
pmufw	<code>&lt;plnx-proj-root&gt;/components/plnx_workspace/pmu-firmware</code>
fsboot	<code>&lt;plnx-proj-root&gt;/components/plnx_workspace/fs-boot</code>

## QEMU Virtual Networking Modes

There are two execution modes in QEMU: non-root (the default) and root (requires sudo or root permission). The difference in the modes relates to virtual network configuration.

In non-root mode QEMU sets up an internal virtual network which restricts network traffic passing from the host and the guest. This works similar to a NAT router. You can not access this network unless you redirect tcp ports.

In root mode QEMU creates a subnet on a virtual Ethernet adapter, and relies on a DHCP server on the host system.

The following sections detail how to use the modes, including redirecting the non-root mode so it is accessible from your local host.

### Redirecting ports in non-root mode

If running QEMU in the default non-root mode, and you wish to access the internal (virtual) network from your host machine (e.g. to debug with either GDB or TCF Agent), you will need to forward the emulated system ports from inside the QEMU virtual machine to the local machine. The `petalinux-boot --qemu` command utilizes the `--qemu-args` option to perform this redirection. The following table outlines some example redirection arguments. This is standard QEMU functionality, refer to the QEMU documentation for more details.

*Table D-2: Redirection Arguments*

QEMU Options Switch	Purpose	Accessing guest from host
<code>-tftp &lt;path-to-directory&gt;</code>	Sets up a TFTP server at the specified directory, the server is available on the QEMU internal IP address of 10.0.2.2.	
<code>-redir tcp:10021:10.0.2.15:21</code>	Redirects port 10021 on the host to port 21 (ftp) in the guest	host> ftp localhost 10021
<code>-redir tcp:10023:10.0.2.15:23</code>	Redirects port 10023 on the host to port 23 (telnet) in the guest	host> telnet localhost 10023

Table D-2: Redirection Arguments (Cont'd)

QEMU Options Switch	Purpose	Accessing guest from host
-redir tcp:10080:10.0.2.15:80	Redirects port 10080 on the host to port 80 (http) in the guest	Type http://localhost:10080 in the web browser
-redir tcp:10022:10.0.2.15:22	Redirects port 10022 on the host to port 22 (ssh) in the guest	Run <code>ssh -P 10022 localhost</code> on the host to open a SSH session to the target

The following example shows the command line used to redirect ports:

```
$ petalinux-boot --qemu --kernel --qemu-args "-redir tcp:1534::1534"
```

This document assumes the use of port 1534 for gdbserver and tcf-agent, but it is possible to redirect to any free port. The internal emulated port can also be different from the port on the local machine:

```
$ petalinux-boot --qemu --kernel --qemu-args "-redir tcp:1444::1534"
```

## Specifying the QEMU Virtual Subnet

By default, PetaLinux uses `192.168.10.*` as the QEMU virtual subnet in `--root` mode. If it has been used by your local network or other virtual subnet, you may wish to use another subnet. You can configure PetaLinux to use other subnet settings for QEMU by running `petalinux-boot` as follows on the command console:

**CAUTION!** *This feature requires sudo access on the local machine, and must be used with the --root option.*

```
$ petalinux-boot --qemu --root --u-boot --subnet <subnet gateway IP>/
<number of the bits of the subnet mask>
```

For example, to use subnet `192.168.20.*`:

```
$ petalinux-boot --qemu --root --u-boot --subnet 192.168.20.0/24
```

# Xilinx IP Models Supported by QEMU

The QEMU emulator shipped in PetaLinux tools supports the following Xilinx IP models:

- Zynq-7000 ARM Cortex-A9 CPU
- Zynq UltraScale+ MPSoC ARM Cortex-A53 MPCore
- Zynq UltraScale+ MPSoC Cortex-R5
- MicroBlaze CPU (little-endian AXI)
- Xilinx Zynq-7000/Zynq UltraScale+ MPSoC DDR Memory Controller
- Xilinx Zynq UltraScale+ MPSoC DMA Controller
- Xilinx Zynq UltraScale+ MPSoC SD/SDIO Peripheral Controller
- Xilinx Zynq UltraScale+ MPSoC Gigabit Ethernet Controller
- Xilinx Zynq UltraScale+ MPSoC NAND Controller
- Xilinx Zynq UltraScale+ MPSoC UART Controller
- Xilinx Zynq UltraScale+ MPSoC QSPI Controller
- Xilinx Zynq UltraScale+ MPSoC I2C Controller
- Xilinx Zynq UltraScale+ MPSoC USB Controller (Host support only)
- Xilinx Zynq-7000 Triple Timer Counter
- Xilinx Zynq-7000 DMA Controller
- Xilinx Zynq-7000 SD/SDIO Peripheral Controller
- Xilinx Zynq-7000 Gigabit Ethernet Controller
- Xilinx Zynq-7000 USB Controller (Host support only)
- Xilinx Zynq-7000 UART Controller
- Xilinx Zynq-7000 SPI Controller
- Xilinx Zynq-7000 QSPI Controller
- Xilinx Zynq-7000 I2C Controller
- Xilinx AXI Timer and Interrupt controller peripherals
- Xilinx AXI External Memory Controller connected to parallel flash

- Xilinx AXI DMA Controller
- Xilinx AXI Ethernet
- Xilinx AXI Ethernet Lite
- Xilinx AXI UART 16650 and Lite

---

**IMPORTANT:** *By default, QEMU will disable any devices for which there is no model available. For this reason it is not possible to use QEMU to test your own customized IP Cores (unless you develop C/C++ models for them according to QEMU standard).*

---

For more information refer to *Zynq Ultrascale+ MPSoC Quick Emulator User Guide (UG1169)* [\[Ref 5\]](#).

# XEN Zynq Ultrascale+ MPSoC Example

This section details on the XEN Zynq® Ultrascale+™ MPSoC example. It describes how to get Linux to boot as dom0 on top of XEN on Zynq Ultrascale+ MPSoC.

## Prerequisites

This section assumes that the following prerequisites have been satisfied:

- You have PetaLinux Tools software platform ready for building a Linux system customized to your hardware platform. Refer to section [Import Hardware Configuration](#) for more information.
- You have created a PetaLinux project from the ZCU102 reference BSP.
  - There are XEN related prebuilts in the `pre-built/linux/images` directory, which are `xen.dtb`, `xen.ub`, `xen-image` and `xen-rootfs.cpio.gz.u-boot`.

## Boot prebuilt Linux as dom0

1. Copy prebuilt XEN images and Linux Kernel image to your tftp directory so that you can load them from u-boot with tftp.

```
$ cd <plnx-proj-root>
$ cp pre-built/linux/images/xen.dtb <tftpboot>/
$ cp pre-built/linux/images/xen.ub <tftpboot>/
$ cp pre-built/linux/images/xen-Image <tftpboot>/
$ cp pre-built/linux/images/xen-rootfs.cpio.gz.u-boot <tftpboot>/
```

2. Boot prebuilt u-boot image on the board with either jtag boot or boot from SD card.
3. Setup tftp server IP from u-boot

```
U-Boot-PetaLinux> setenv serverip <TFTP SERVERIP>
```

4. Load XEN images and kernel images from u-boots

```
U-Boot-PetaLinux> tftpboot D80000 xen.dtb
U-Boot-PetaLinux> tftpboot 80000 xen-Image
U-Boot-PetaLinux> tftpboot 1000000 xen.ub
U-Boot-PetaLinux> tftpboot 2000000 xen-rootfs.cpio.gz.u-boot
U-Boot-PetaLinux> bootm 1000000 2000000 D80000
```

## Kernel Configuration Requirement

In order to run Linux kernel as dom0, the following options are required to be on:

- CONFIG\_XEN
- CONFIG\_HVC\_DRIVER
- CONFIG\_HVC\_XEN
- CONFIG\_XEN\_NETDEV\_BACKEND

The reference PetaLinux project has already enabled them by default.

## XEN Device Tree Requirements

You can see the `project-spec/meta-user/recipes-dt/device-tree/files/xen-overlay.dtsi` for how the XEN configuration should be in a DTS. Note that DTS for QEMU platform is different from hardware. Use `xen-qemu.dts/xen-qemu-overlay.dts` when running on QEMU.

The DTS file for XEN, should be the same as for plain Linux, with a few entries added to the chosen node. The `xen,dom0-bootargs` corresponds to the Linux Kernel command line. Here is an example:

```
chosen {
#address-cells = <0x2>;
#size-cells = <0x1>;
xen,xen-bootargs = "console=dtuart dtuart=serial0 dom0_mem=512M bootscrub=0
maxcpus=1 timer_slop=0";
xen,dom0-bootargs = "console=hvc0 earlycon=xen earlyprintk=xen maxcpus=1";
dom0 {
compatible = "xen,linux-zimage", "xen,multibootmodule";
reg = <0x0 0x00080000 0x3100000>;
};
};
```

If you want to try XEN on QEMU, you will need to disable the other CPUs except CPU0 in the DTS, otherwise, QEMU will run very slow since it is a single threaded application:

```
cpus {
cpu@1 {
device_type = "none";
};
cpu@2 {
device_type = "none";
};
cpu@3 {
device_type = "none";
};
};
```

The steps to create xen-qemu.dtb (similar to hardware) are detailed below:

1. Copy xen-qemu.dts as system-top.dts in project-spec/meta-user/recipes-dt/device-tree/files/
2. Change the device-tree append in meta-user as follows:

```
SRC_URI_append = " \
    file://system-top.dts \
    file://xen-qemu-overlay.dtsi \
    file://xen-overlay.dtsi \
"
FILESEXTRAPATHS_prepend := "${THISDIR}/files:"

do_compile_prepend () {
    install -m 644 ${WORKDIR}/xen-overlay.dtsi ${dts_dir}/
    install -m 644 ${WORKDIR}/xen-qemu-overlay.dtsi ${dts_dir}/
}
```

3. Build petalinux-build -c device-tree.

The system.dtb will be updated after the above command.

## Rebuild XEN

Assuming your PetaLinux project is created from the Zynq Ultrascale + MPSoC PetaLinux reference BSP. XEN built from the Yocto recipe, you can rebuild the xen.ub as follows:

- Add EXTRA\_IMAGE\_FEATURES = "debug-tweaks" to <plnx-proj-root>/build/conf/local.conf
- Build XEN:  
\$ petalinux-build -c xen-image-minimal
- Follow the example mentioned above to generate the device tree.
- The build artifacts will be in <TMPDIR>/deploy/images/plnx\_aarch64.  
xen-image-minimal-plnx\_aarch64.cpio,  
xen-image-minimal-plnx\_aarch64.cpio.gz.u-boot and  
plnx\_aarch64-system.dtb and xen.ub with the XEN configuration.  
You have to copy the required images to images/linux.
- Copy the images from the deploy directory to images/linux.

**Note:** By default, the petalinux-build command does not build XEN. The default root file system does not contain the XEN tools. You have to use XEN rootfs.

# Obsolete Features

This section details the obsolete features/options in the PetaLinux Commands.

1. petalinux-create
  - a. -t libs: You have to use the apps methodology to develop or install libraries.
  - b. -t libs --priority: This option is no longer supported.
  - c. -t generic: Generic components are no longer supported
2. petalinux-config
  - a. --search: The entire search path implementation and all its sub options are no longer supported.
3. petalinux-build
  - a. --makeenv - You have to provide your flags in the corresponding bbappends or in Makefile
4. petalinux-package
  - a. --bsp --no-extern: You have to explicitly copy the local external components.
  - b. --bsp --no-local: This option is no longer supported.
  - c. --firmware: This option is no longer supported.
  - d. --image -c rootfs: You have to choose the type of File system from petalinux-config
5. petalinux-boot
  - a. --qemu --qemu-gdb: You can directly use --qemu-args option to ask qemu to launch gdb.
6. petalinux-util
  - a. --update-sdcard: You have to update the sdcard manually. For more details, refer to [Configuring SD Card ext filesystem Boot](#).

# Common Errors and Recovery

This section details the common errors that appear, while working with the PetaLinux commands, and also lists their recovery steps in detail.

The common errors and their recovery methods are:

## 1. TMPDIR on NFS

"ERROR: OE-core's config sanity checker detected a potential misconfiguration"

Either fix the cause of this error or disable the checker at your own risk (see `sanity.conf`). Following is the list of potential problems / advisories:

```
The TMPDIR: /home/user/xilinx-kc705-axi-full-2016.4/build/tmp cannot be located on NFS.
```

The TMPDIR cannot be on NFS, therefore, it will throw an error while parsing. You have to change it from `petalinux-config` and then provide any local storage.

```
Yocto-settings --> TMPDIR
```

## 2. Bitbake cannot run always.

Only one instance of bitbake runs for one project. If the previous build is exited abruptly, there are chances for bitbake exiting non-gracefully for the current build.

```
to reciver: rm -rf <plnx-proj-root>/build/bitbake.lock
```

## 3. App/module name having ' \_ '

If the app name is "plnx\_myapp", bitbake throws an error. A version number has to be entered after ' \_ '.

For example, `myapp_1` is an accurate app/module name.

To recover, you have delete the app created and also delete the line in  
`<plnx-proj-root>/project-spec/meta-plnx-generated/recipes-core/images/petalinux-image.bbappend`

```
IMAGE_INSTALL_append = " plnx_myapp"
```
