## Determining Wire Gauge

## Example:

Power supply voltage equals
12 volts. Load equals 3 electromagnetic locks. Each lock requires $\mathbf{0 . 2 8 0} \mathbf{~ a m p s}$ of current.

Total current draw equals ( $3 \times 0.280=0.840 \mathrm{amps}$ ). Round off current to $\mathbf{1}$ Amp. (Always round off in an upward direction.) Distance from farthest electromagnetic lock equals $\mathbf{1 0 0}$ feet. Use the 12 V chart and locate the 1.00 Amp column along the top of the chart. Select the distance in left column closest to the distance of the farthest lock. The wire gauge required can be found by cross referencing the rows vertically and horizontally.
(\#14 AWG).

## Types of Wire:

Hookup wire is available in both solid and stranded wire types. Stranded wire is the accepted standard for system hookup as it is more flexible and less likely to break. It's made of several small-diameter wires twisted together to form one larger-diameter conductor. To prevent the strands from separating, stranded wire is usually tinned (solder applied to ends of wire). This makes connections easier and prevents the wire from fraying.

## Wire Gauge:

Wire is given a gauge number to classify it by its size or thickness. American wire gauge (AWG) is the most common measurement for electrical wire size - the lower the wire gauge number, the larger the wire diameter and the greater the current carrying capability.

## Wire Insulation:

The wire insulation should be UL or CSA approved for the maximum voltage to which the wire will be subjected. Normally, the wire rating is three to six times greater than the maximum voltage to be applied to the wire.
