AM-PUB098

PREFACE

The present state of MOS LSI semiconductor technology has permitted powerful and complex general-purpose processors to be economically incorporated into single silicon chips. This capability ushers in a new era of system design, where for the first time low cost tools are available for solving many complex problems. Significant levels of computing power are now available inexpensively and can be used both to lower the cost of high performance systems and to improve the efficiency of programmers in their increasingly more complex tasks.

The AmZ8000 Family is the first integrated processor family to fully exploit this new era, breaking tradition with the legacy of compromised performance dictated by past manufacturing technologies. The two processors in the family incorporate many of the features heuristically evolved from both minicomputer and main-frame systems. This gives the applications programmer, the systems programmer and the system designer the power and flexibility required for today's complex systems.

This Data Book is one of a series of documents that support the AmZ8000 Family. The AmZ8000 Processor Instruction Set book (AM-PUB086) provides a complete, detailed description of all the processor instructions; the AmZ8000 Interface Manual (AM-PUB089) provides a detailed discussion of the CPU interface and its use with several support devices; AmZ8010 Memory Management introduction (AM-PUB093). Additional information is currently being prepared for publication.

CHAPTER 1

Introduction

INTRODUCTION

Advanced Micro Devices has undertaken a significant commitment to the world of 16-bit fixed-instruction-set processors. AMD is bringing to the market:

- A new, advanced processor architecture,
- A complete family of LSI peripheral circuits,
- A complete family of system support circuits,
- A complete family of memories and memory support circuits,
- Complete technical documentation,
- Effective development system products,
- Extensive support software.

This book describes all of these items in as much detail as is available at press time. Future editions will be propagated as new information is generated. Some of the data included here is preliminary and is intended to aid long-term planning. The factory should be contacted for the latest technical data on specific products and for the latest product availability information.

A large majority of future microprocessor applications will be serviced by a combination of single-chip microcomputer products such as the Am8048 series and by 16-bit microprocessors such as the AmZ8000. Where applications are simple enough, the 8-bit microcomputer chips will tend to be used. Increasing software costs and throughput requirements will cause the 16-bit CPUs to dominate the balance of the designs because they can answer these problems more efficiently. Conventional 8-bit microprocessors will serve a shrinking share of new designs.

In addition to significant increases in throughput that flow directly from the 16-bit structures, improved technology and more sophisticated architectures add even more performance. Software cost savings are being realized due to more powerful instruction sets, and in conjunction with sophisticated high-level languages such as PASCAL. Language compilers allow the programmers to write, debug and document programs in a shorter time span. This is vitally important for such a labor-intensive activity where costs are rapidly rising. The declining costs of technology-intensive LSI hardware can be used to improve software costs.

The AmZ8000 processors, in terms of resources, system features, instructions, interface and architecture, represents a major advance in microprocessor sophistication and system-level performance. The processors form the heart of a large family of components, systems, software, documentation and support. In addition to existing peripheral chips, a variety of new advanced peripherals has been designed to support the AmZ8001 and AmZ8002 processors. Figure 1 shows these new MOS/LSI components.

Several types of products are available for buffering, driving, latching, decoding and control functions. These are useful within the system as well as for external interface and for implementing memory subsystems. Additional specialized components have been designed for control of specific memory subsystem functions such as refreshing and error correction.

A wide variety of memory devices are available to support the AmZ8000 Family. Advanced Micro Devices manufactures many types of RAMs, ROMs, PROMs, EPROMs and FIFOs. Memories, of course, are essential elements in any processor design. Indeed, processors can be considered as tools for converting logic gates and algorithms into memory cells, thus providing user access to the excellent levels of technology available via memories.

An AmZ8000 Evaluation Board is available from Advanced Micro Computers for quick hands-on experience with the AmZ8000. It is a complete small computer with RAM, ROM and several I/O ports. Available software includes a resident monitor and a simple line-by-line assembler. The AmSYS™ 8/8 Microcomputer Development System supports the AmZ8000 Family as well as other microprocessors such as the Am8080, Am8085 and Z80. The system includes RAM, dual 8 inch Floppy Disk drives and several serial and parallel interfaces.

A powerful set of development software is available with the AmSYS /8 to make the complex process of product development easier and faster. The software includes a sophisticated Disk Operating System, Macro Assemblers, a linking loader, a powerful editor and debugger and a PASCAL compiler.

Advanced Micro Devices has an educational department which offers courses on the AmZ8000 microprocessor family, Am2900 bit-slice family and on related topics. Check with your AMD sales office for course outlines and schedules.

Advanced Micro Devices was conceived on the premise that there was a place in the semiconductor community for a manufacturer dedicated to excellence. This attitude is manifested in many ways throughout the structure of the company and has been maintained consistently throughout the life of AMD. In product assurance procedures, Advanced Micro Devices is unique. Only AMD processes all integrated circuits, commercial as well as military, to the demanding requirements of MIL-STD-883. The AmZ8000 microprocessors and its family of support devices are no exception; every component is 100% screened to MIL-STD-883, Method 5004, Class C.

real time controllers and for
intelligent terminals*

Processor Architecture

PROCESSOR ARCHITECTURAL OVERVIEW

INTRODUCTION

The AmZ8000 is an advanced high-end 16-bit microprocessor designed to span a wide variety of applications. Its features allow it to be used effectively in complex, high-throughput systems, yet it remains efficient for simpler systems as well. The AmZ8000 is available in two versions: the AmZ8001 48-pin segmented CPU and the AmZ8002 40-pin non-segmented CPU. The difference between the two devices is the addressing range: the AmZ8001 can directly address eight megabytes of memory per memory space and the AmZ8002 can directly address 65 kilobytes of memory per memory space. To meet the requirements of complex, memory intensive applications, the AmZ8010 Memory Management Unit offers logical-to-physical address translation and several memory protection features.

The AmZ8000 has abundant CPU resources that include numerous registers, many data element types, a large instruction set and several addressing modes. Not only are the CPU resources abundant, but they exhibit a consistency and regularity not found in previous microprocessor architectures. Regularity of register organization, data types, instructions and addressing modes

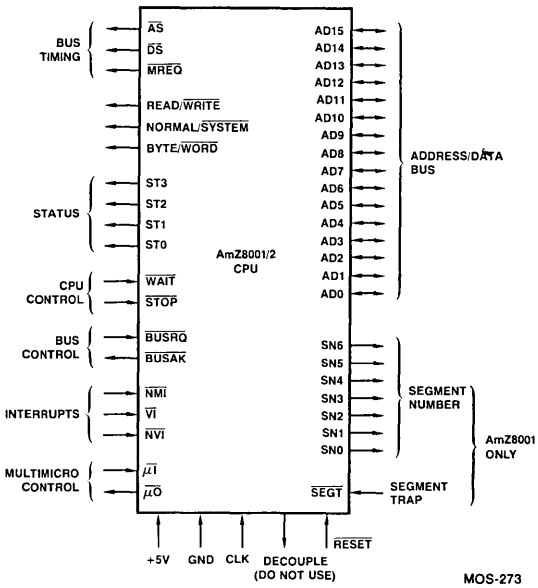

greatly simplifies the programming process and reduces program length.

Compiler, compiler-produced, and operating system code all run efficiently on the AmZ8000. The AmZ8000 supports compilers with features such as a consistent instruction set, large address space, relocation, multiple stacks and some specific instructions (Push, Pop, Increment, Test).

Operating systems are supported by features such as system and normal modes, system and normal stacks, specific instructions (System Call, Load Program Status and privileged instructions), and by a sophisticated interrupt and trap structure. This structure includes three types of interrupts (non-maskable, non-vectored and vectored) and four types of traps (system calls, illegal instructions, privileged instructions and segment errors).

Multi-microprocessor systems are supported in software by exclusion and synchronization instructions and in hardware by the Micro In and Micro Out interface lines.

2

CPU Pin Configuration

General-Purpose Registers

CPU RESOURCES

Not only must the address space of an advanced architecture be large, but its CPU resources must be abundant enough for the solution of large problems.

Registers

The AmZ8000 offers sixteen 16-bit general-purpose registers in addition to special system registers. All 16 general-purpose registers may be used as accumulators and all but R0 as index registers and stack pointers. The first eight registers (R0-R7) can be used as sixteen 8-bit byte registers. For operations requiring long words (32 bits), the general purpose registers are grouped in pairs (RR0-RR14). For certain 64-bit operands (i.e., multiplication and division with long words), the register set is grouped in quadruples (RQ0-RQ12) to form 64-bit registers.

The CPU instruction set supports seven main data types: bits, BCD digits, bytes, words (16 bits), long words (32 bits) byte strings and word strings. Additionally, many other data elements such as memory addresses, I/O addresses, segment table entries and program status words may also be manipulated.

Stacks

The AmZ8000 allows data stacks to be located anywhere in memory. Push and Pop instructions allow any register (except RR0 (AmZ8001) and R0 (AmZ8002)) to be designated as data stack pointers. Call and Return instructions, as well as interrupts and traps use the (implied) linkage stack pointers. For the AmZ8001, the register pair RR14 (R14 and R15) is the linkage stack pointer, while for the AmZ8002 register R15 is the linkage stack pointer.

The CPUs operate in one of two selectable modes: System and Normal. The System mode is sometimes called a Supervisor or Privileged mode and the Normal mode is sometimes known as User or Task or Nonprivileged mode. Separation from system information is provided by a dual set of linkage stack pointers. In the AmZ8001, the register pair R14' and R15' will be used in the System mode as the implied stack pointer, while the AmZ8002 will use the R15' register. Because the implied stack pointers are part of the general-purpose register group, the user can manipulate the stack pointers with any of the instructions available for register operation.

Program Status Information

This group of status registers contains the program counter (PC), the flag and control word (FCW) and the new program status area

pointer (NPSAP). When an interrupt or trap occurs, the Program Status registers (PC and FCW) are saved on the system stack. An Identifier that describes the reason for interruption is also saved. The NPSAP provides the memory location for loading new information into the PC and FCW registers.

The CPU Control bits occupy the upper byte of the Flag and Control Word. The bits may be read and loaded by the privileged LDCTL instruction. The Control bits are:

- SEG Segmented Mode Enable
- S/N System or Normal Mode
- VIE Vectored Interrupt Enable
- NVIE Non-Vectored Interrupt Enable

The SEG bit indicates segmented operation in the AmZ8001 if set to 1. When the SEG bit is 0, the AmZ8001 is forced into non-segmented operation and will interpret all programs as non-segmented. In this mode, the AmZ8001 executes AmZ8002 non-segmented code. The AmZ8002 SEG bit is always set to 0 and cannot be altered by the programmer.

The CPU Flags occupy the lower byte of the Flag and Control Word. The privileged instructions LDCTLB, RESFLG and SETFLG are used to load, read, set and clear the flags. The Flag bits are:

- C Carry Result
- Z Zero Result
- S Sign Result
- P/V Even Parity or Overflow
- DA Decimal Adjust
- H Half Carry

Interrupt and Trap Structure

The AmZ8000 provides a flexible and powerful interrupt and trap structure. Interrupts are asynchronous events triggered by an external device requesting service, while traps are synchronous events occurring upon the execution of certain instructions. The AmZ8000 supports three types of interrupts (non-maskable, vectored and non-vectored) and four traps (system call, unimplemented instruction, privileged instructions and segmentation trap). The vectored and non-vectored interrupts are maskable. When an interrupt or trap occurs, a 16-bit identifier (in addition to the PC and FCW registers) is pushed onto the system stack.

AmZ8001 Program Status Registers

AmZ8001 New Program Status Area Pointer

AmZ8002 Program Status Registers

AmZ8002 New Program Status Area Pointer

MOS-275

The identifier contains the reason for the trap or interrupt. For internal traps, the identifier is the first word of the trapped instruction. For external traps or interrupts, the identifier is placed on the data bus by the interrupting or trapping peripheral.

Memory Refresh

The AmZ8000 CPUs contain a refresh counter for automatically refreshing dynamic memory. A 9-bit row counter can address up to 256 rows and thereby assures compatibility with the latest 64K dynamic memories. It is incremented by two each time the rate counter reaches end-of-count. The rate counter determines the time between successive refreshes and can be programmed from 1 to 64μsec assuming a 4MHz CPU clock. The refresh mechanism can be disabled under software control.

Large Addressing Space

High-level languages, sophisticated operating systems, large data bases, large programs and decreasing memory prices are all accelerating the trend toward larger memories. The AmZ8000 processors can directly address up to eight megabytes of memory per address space. Four convenient, separate address spaces exist in both versions of the AmZ8000 processors: code and data for both the system mode and the normal mode.

Each space is addressed by a 16-bit or 23-bit address. Thus the total system addressing for a user is 32M bytes for the AmZ8001 and 256K bytes for the AmZ8002. Instructions are always addressed on word boundaries (even-numbered addresses) while data is addressed by byte, word, long word, or quadruple word addresses. A specific bit can also be addressed within a byte or word address.

The AmZ8000 also has a 16-bit I/O addressing space which is separate from the memory address space. An attractive complement of single element I/O and block I/O instructions exist for bytes and words.

Additionally, many useful memory management features, are provided by the AmZ8010 Memory Management Unit when used as a companion to the AmZ8001. These features will extend the life of the architecture by avoiding memory address limitations that have hampered microprocessors in the past.

The only drawback of the long addresses required by the large addressing space is the larger size of the instructions and the need for register pairs for some addressing modes. This problem is minimized by segmented addressing features, the use of short addresses in many situations, relative addressing ability and by the availability of a large number of general-purpose registers.

Memory Management

AmZ8001 programs can directly access the entire address space. A full address mode is available where 23 bits are set aside within the instruction for the address. The AmZ8001 also offers a mode called short offset mode in which the same address can be expressed by 16 bits in many situations where the higher-order offset bits are zeros.

Alternative methods commonly employ fixed internal registers that contain address extensions. Although these methods may use shorter instruction addresses, the byte savings are lost be-

cause many instructions are required to explicitly manage the contents of the registers. The AmZ8001 can use variations of these methods; however, it also provides direct addressing that removes the necessity for those extra instructions and unburdens the programmer from managing the register contents.

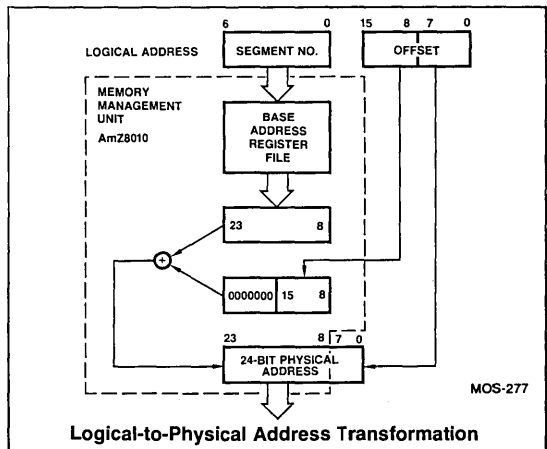

Another important feature provided to the system designer is the ability to distinguish externally between System code and Normal code, and in both cases, to distinguish between instruction space and data space. If this feature is utilized, the AmZ8001 can address up to 32 megabytes of memory. Aided by system programs, the memory management unit can help manage the large address space on behalf of the user.

Segmentation is the mechanism provided to address the large amount of memory addressable by the AmZ8001. A segmented address is made of two parts: a segment number and an offset value. The AmZ8001 can designate up to 128 segments that reference areas of memory variable in size from 256 bytes to 64 kilobytes, in increments of 256 bytes.

The only difference between running segmented or non-segmented code is the number of bytes per address and the number of registers used for full addresses. Code written for the non-segmented AmZ8002 can run in one segment of the segmented AmZ8001. Thus, full compatibility exists between the two versions.

The AmZ8010 Memory Management Unit essentially doubles the silicon area available for the processor function (and adds pins as well). Hence, it also doubles the hardware available to the designer for implementing more high-end features than otherwise would have been possible. Some of these features include variable sized segments, more sophisticated dynamic memory relocation and several types of memory protection attributes.

Addresses manipulated by the programmer are called logical addresses. The MMU translates these logical addresses to physical addresses required for accessing the memory. This address transformation makes user software addresses independent of the actual physical memory thus freeing the user from specifying where information is actually located in memory. The translation table in the Memory Management Unit associates the 7-bit segment number with the base address of the physical memory segment. The 16-bit offset portion of the logical address from the CPU is added to the physical base address to obtain the actual physical address. The system may dynamically reload translation tables as tasks are created, suspended, or changed. Memory protection features prevent illegal uses of segment, such as writing into a write-protected zone. Several Memory Management Units may be used with a single CPU.

Instructions

Compared to other microprocessors or to 16-bit minicomputers, the number and power of individual instructions has been greatly increased. Over 110 distinct instruction types are available with the AmZ8000. Byte, word and long-word data elements can be processed by all the core instructions. Each instruction, with few exceptions, can use most of the addressing modes. Over 410 meaningful combinations of instruction types, data elements and addressing modes are available.

The instruction set provides nine basic instruction groups: Load and Exchange, Arithmetic, Logical, Program Control, Bit Manipulation, Shift and Rotate, String Manipulation, CPU Control, and Input/Output. Instructions vary in length from one to five words depending on the operation and addressing mode. String and block move instructions are interruptable to enhance response time. Also provided are signed-multiply and signed-divide instructions implemented in hardware for both 16-bit and 32-bit values.

The instruction set provides several user-selectable addressing modes including five main modes: Register (R), Indirect Register (IR), Direct Address (DA), Indexed (X) and Immediate (IM). For certain instructions, there are other modes: Base Address (BA), Base indexed (BX), Relative Address (RA), Autoincrement and Autodecrement.

Code Density

For a given hardware technology, microprocessor speed is largely dependent on the number of executed instruction words needed for a particular function. Therefore, code density becomes an important issue in high-performance systems. The AmZ8000 offers several advantages in this respect.

The number of words required to specify frequently executed instructions has been minimized. A special group of high frequency instructions has been designed into single words. This not only improves speed, but increases code density as well.

A short offset mechanism is also designed to allow certain 23-bit addresses to be reduced to a single word. It can be automatically invoked by assemblers and compilers.

Additional large improvements in program size and speed result from the consistent and regular architecture, and the greater power of the instruction set. These factors allow fewer instructions to accomplish a given task.

Compiler Efficiency

It is tempting to adapt a computer architecture that efficiently executes a particular high-level language. Any special-purpose match between an architecture and a language is efficient for that language, but most likely inefficient for unrelated languages. Since the AmZ8000 is a general-purpose microprocessor, general language support has been provided through the inclusion of features that ease typical compilation and code-generation problems for all high-level languages.

Among these features is the regularity of the AmZ8000 addressing modes, registers and data element types. In addition, any

register can be used as a data stack pointer with the Push and Pop instructions. Segmentation and relocation are useful features for high-level language procedure implementation. Procedure parameter passing is aided by these features as well as by special increment and decrement instructions which are useful in stack frame allocation and de-allocation. Base Address and Base Indexed addressing modes are also useful for stack frames. Useful testing and comparison of data, logical evaluation and initialization are made very efficient by several special instruction types. Compilers and assemblers handle character blocks quite frequently and the string manipulation instructions provide unusual efficiency compared to software simulations of these important tasks.

Operating System Support

Interrupt and task-switching features are included to improve operating system implementations. The memory-management and compiler-support features also contribute effectiveness in this environment.

The interrupt structure has three levels: non-maskable, non-vectored and vectored. When an interrupt occurs, the program status is saved on the stack with an indication of the reason for this state switching. A new program status is then loaded from memory and execution proceeds using the new Program Counter. In the case of a vectored interrupt, each vector points to a unique new Program Counter, providing direct access to particular service routines.

The System/Normal partition improves operating system integrity and organization. In the System mode, all operations are allowed; in the Normal mode, certain system instructions are prohibited. The System Call instruction allows a controlled switch of mode, and the implementation of traps enforces these restrictions. Dual linkage stack pointers also support the System/Normal partition.

Traps result in the same type of program status saving as interrupts; in both cases, the information saved is pushed on the system linkage stack and keeps the normal stack undisturbed. The Load Multiple instruction allows the contents of any group of the general registers to be saved and restored efficiently in memory. Running system programs can cause selective or general program status changes under direct software control. Finally, exclusion and serialization can be achieved with the "atomic" Test and Set instruction that synchronizes cooperating processes.

Multiprocessor Support

The AmZ8000 exclusion/serialization mechanism is designed for multimicroprocessor systems. Any CPU in a multiprocessor system can exclude all other asynchronous CPUs from any critical shared resource by using the Micro In (μ I) input and Micro Out (μ O) output in conjunction with several coordinating instructions.

In addition, the large address space of the AmZ8000 proves to be a beneficial feature in most multiprocessor systems.

AmZ8000 Microprocessor Family

CHAPTER 3

System Architecture

A wide variety of peripheral circuits are easy to use with the AmZ8000.

SYSTEM ARCHITECTURE OVERVIEW

INTRODUCTION

The AmZ8000 CPU and peripheral device family support a variety of interface exchanges. The AmZ8000 processors are designed to handle five basic types of transfers: memory operations, I/O operations, resource request daisy chain, bus request daisy chain and interrupt request daisy chain. These interface exchanges share most of a common set of control signals. Most of the AmZ8000 peripherals use a similar control structure and some subset of the five basic transfer types. Some of the features of the system structure are:

- Juxtaposition and coordination of five different buses.
- Transparent bus for asynchronous peripheral operations.
- Multiplexed I/O and memory operations.
- Multiplexed Address and Data transfers.
- Full parallel 23-bit addresses.
- Preemptive interrupt daisy chains.
- Interrupt protocol allows vectors for peripheral identification.
- Resource allocation uses exclude/grant daisy chain.
- Bus requests use daisy chain for contention resolution.

Memory Operations

The AmZ8000 CPU offers a powerful combination of memory access techniques to a word organized memory. The CPU distinguishes between instructions, data and stack entries in both System and Normal modes and outputs a combination of status and bus timing signals. The status lines consist of four outputs which indicate the type of bus access; a Normal/System line to aid in selecting system or user memory space; a Byte/Word output line to allow addressing of an individual byte or a 16-bit word; and the Read/Write output indicating the direction of data flow.

Both versions of the AmZ8000 exhibit the identical set of status lines thereby allowing convenient access to separate 64K byte address spaces: system code, normal code, system data, normal data. The AmZ8001, through its additional seven segment number outputs allows extension of its address spaces to 8M bytes each. The AmZ8010 Memory Management Unit can further enhance memory space usage and allocation in the AmZ8001. The MMU offers the capability of generating a 24-bit physical address from the 23-bit logical addresses emitted by the CPU. Thus the AmZ8001 can directly address any 8M bytes within a 16M byte physical memory. Furthermore, memory address seg-

Status Line Codes

ST3-ST0	Definition
0000	Internal operation
0001	Memory refresh
0010	I/O reference
0011	Special I/O reference
0100	Segment trap acknowledge
0101	Non-maskable interrupt acknowledge
0110	Non-vectored interrupt acknowledge
0111	Vectored interrupt acknowledge
1000	Data memory request
1001	Stack memory request
1100	Program reference, nth word
1101	Instruction fetch, first word

ments can be of any size that is a multiple of 256 bytes and may overlap. Each Memory Management Unit may translate up to 64 address segments. If more segments are required, several Memory Management Units may simply be paralleled.

The AmZ8000 bus timing signals consisting of three signals: MREQ whose level indicates a memory or I/O type transfer; AS which is an address strobe (an address is indicated valid by its rising edge); and DS which is the data strobe (data read or written is also indicated valid by the rising edge of DS). A typical memory fetch cycle occurs within three CPU clock cycles thereby allowing the usage of moderate access time memories for price/performance enhancement. A WAIT bus control input is also available on the CPU thus allowing even slower memory operation.

I/O Operations

I/O operations between the AmZ8000 CPU and its peripherals are transacted on the same multiplexed address/data bus lines and are distinguished only by status outputs. (MREQ HIGH specifies an I/O operation while status lines ST0-ST3 specify either a standard I/O address space or a special I/O address space: for example, an AmZ8010 MMU.) The I/O address space can, therefore, be two separate 16-bit address spaces, in addition to the memory space, if the status lines are decoded in conjunction with MREQ signal. The large I/O address space allows great

Figure 1. Typical Memory Organization.

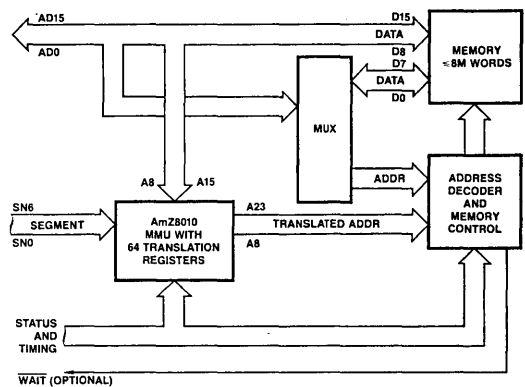

Figure 2. AmZ8010 Managed Segmented Memory.

System Architecture

versatility for accessing intensive register oriented peripherals: AmZ8000 peripherals typically follow the philosophy of allowing read and write operations to all their internal registers.

I/O mapped 8-bit peripherals can be located on either the upper or lower half of the address/data bus for data transfers; the AmZ8000 CPU duplicates a data byte on both halves of the bus when executing a byte write I/O operation.

A byte read I/O operation follows the same principle as byte read memory operations: Odd addresses refer to the low-order byte (AD0-AD7 bus) and even addresses to the high-order byte (AD8-AD15 bus).

Eight and 16-bit wide peripherals can be intermixed on the same bus, as the AmZ8000 provides both byte and word I/O oriented instructions, as well as Block I/O instructions for rapid data transfers (i.e., I/O peripheral register initialization).

AmZ8000 peripherals are not required to be synchronous with the CPU, because no clock is transmitted. AS and DS strobe signals provide the timing. In addition, the CPU inserts an automatic wait state whenever an I/O operation is performed. Additional wait states can be inserted by a slow peripheral by activating the AmZ8000 CPU wait status input.

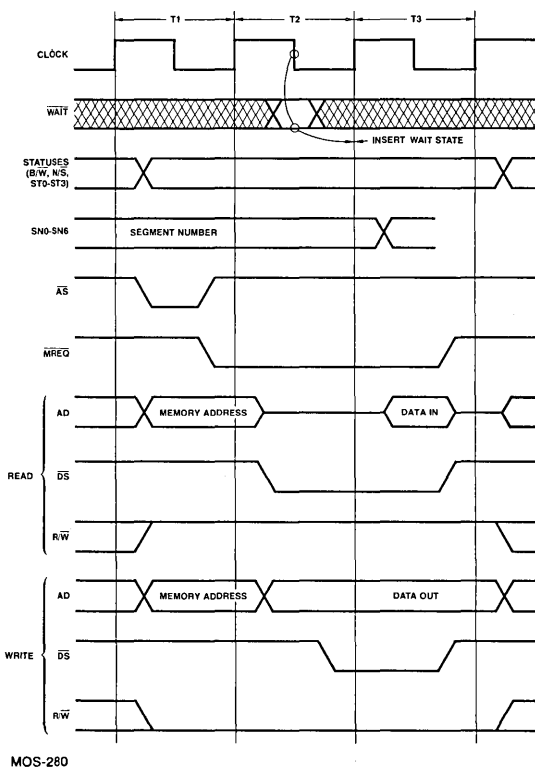

Figure 3. Memory Read and Write Timing.

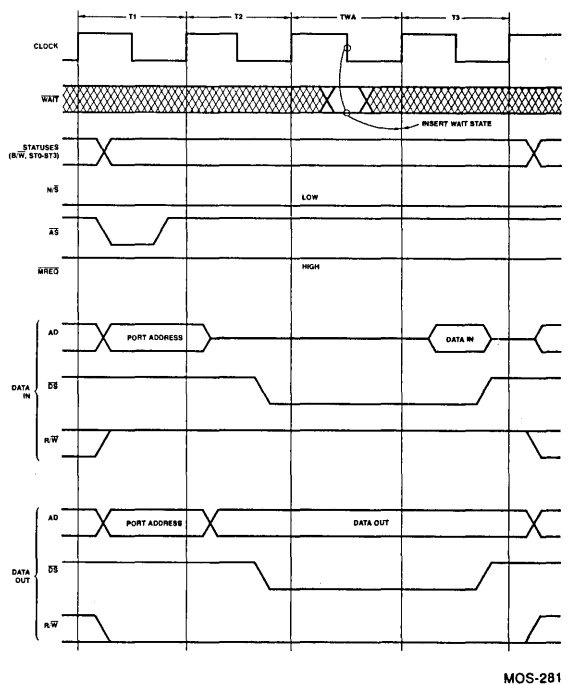

Figure 4. Input/Output Timing.

Interrupt Daisy Chain Protocol

An interrupt daisy chain protocol enables peripherals to act as slaves to the CPU. In contrast to I/O transactions which occur on the data bus in an orderly fashion; each peripheral, with interrupt capability, may attempt to use it simultaneously with another interrupting device. A daisy chain link between peripherals implements a distributed arbitration policy between interrupt requests to achieve an orderly, prioritized sharing of the CPU's resources.

The majority of the AmZ8000 family peripherals have the ability to request interrupts due to several internal reasons (for example, the AmZ8036 CIO can have three reasons to interrupt and the AmZ8030 SCC, eight). The peripheral itself contains an internal

interrupt structure for prioritizing its internal interrupt request sources; for requesting service according to its priority status among other peripherals sharing the system bus; for outputting a proper vector identification, with or without additional status bits, when acknowledged by the CPU. The 8-bit vector allows efficient program transfers to the appropriate service routine without additional polling of the peripheral by the CPU. The peripheral self-vectoring and daisy chain prioritizing precludes the requirement for an additional interrupt controller device in the system.

The AmZ8000 CPU recognizes three interrupt inputs (non-maskable, vectored, and non-vectored), and a segmentation trap input (normally intended to be generated by an AmZ8010 MMU).

Interrupt inputs are asynchronous, and the interrupt acknowledge is decodable from the ST0-ST3 status lines for each interrupt type. An explicit completion code must be emitted by the CPU to terminate some peripheral's interrupt service. An appropriate I/O instruction easily accomplishes it.

To ensure data integrity and proper settling of IEO signals in the daisy chain link, the AmZ8000 CPU automatically inserts five wait states following interrupt acknowledge and before asynchronously strobing in the peripheral's identification vector ("Identifier"). The peripheral may activate the CPU's WAIT line and cause additional wait cycles, if required.

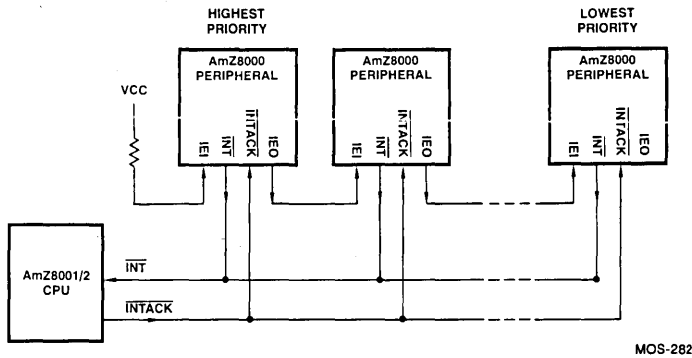

Figure 5. Interrupt Daisy Chain Connections.

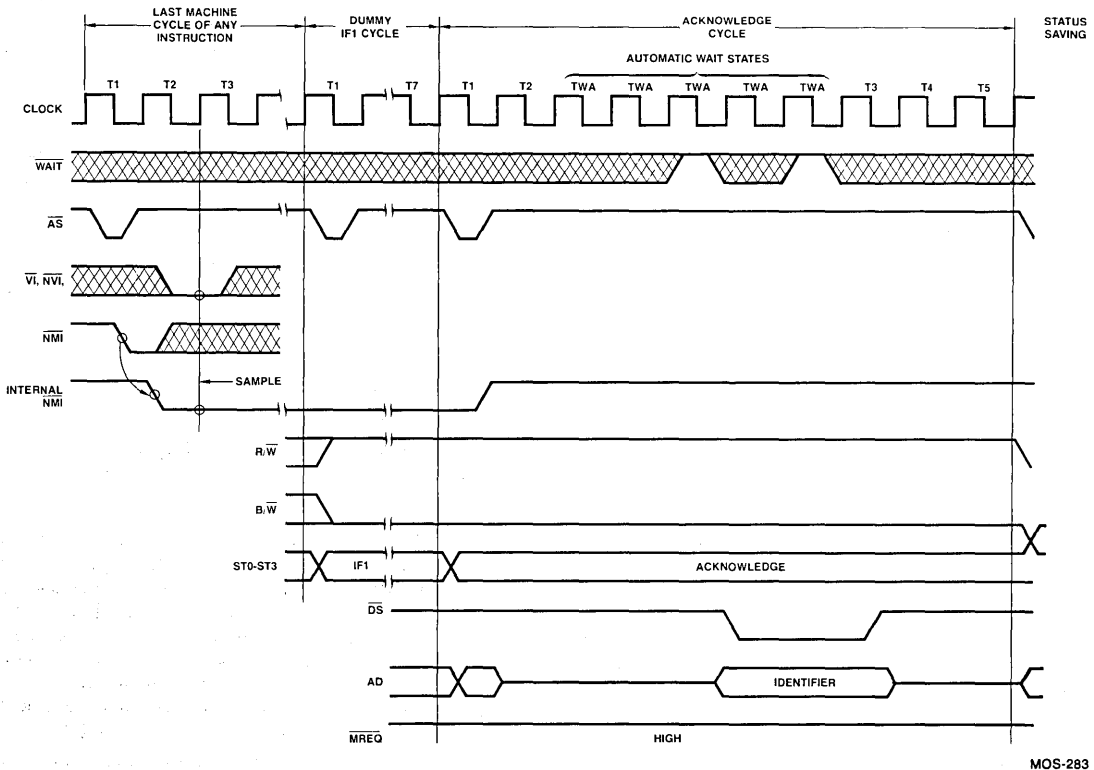

Figure 6. CPU Interrupt and Segment Trap Request Acknowledge Timing.

Peripheral Internal Interrupt Protocol

In general, AmZ8000 family peripherals have three bits for control and status of the internal interrupt logic: an Interrupt Pending bit, an Interrupt Under Service bit and an Interrupt Enable bit. For a multisourced internal interrupt structure, the three above bits are duplicated for each interrupt source, and the interrupt sources are internally prioritized. Lower priority peripherals in the daisy chain link are disabled by the status of another internal list: Disable Lower Chain bit. The peripheral will output a vector for interrupt source identification, when acknowledged by the CPU, according to the status of its No Vector bit. The 8-bit vector (usually defined by an internally programmed register) may include status information as specified by the Vector Include Status bit.

Resource Request Chain Protocol

Multimicroprocessor systems are well supported in hardware and software. Resources, like buses with their associated peripherals or common memories, are easily shared in an orderly and expedient fashion by several CPUs in a system. In general, the resource user need not be a CPU (i.e., it could be an I/O Channel Processor, an Arithmetic Processor, etc.) as long as it can implement a meaningful resource sharing protocol. This is in contrast to a bus request chain (i.e., DMA operations) in which system exists a default master and a defined bus with a tailored protocol. The AmZ8000 CPU supports resource protocol with two hardware pins: the MultiMicro Out (μO) to issue requests for the resource and the MultiMicro In (μI) to recognize or test the state of the resource. Four special instructions allow the CPU to test and request a resource, and to exclude or allow other users to the resource. These functions are particularly interesting with the

eight megabyte AmZ8001 CPU address space capability for multiple microprocessor systems with large shared memory requirements.

A resource request protocol is easily implemented in hardware through simple SSI logic where each resource user is connected to the resource-sharing system by four unidirectional lines.

Unlike an interrupt or bus request chain no user is a default master and no user can therefore be preempted. The resource request protocol uses the request algorithm described below:

1. A user process checks the status of the μST (resource status) line to see if the resource is busy. (The AmZ8000 CPU would look at its μI input pin via the privileged MBIT instruction.)
2. If the μST line is active, then another user is either using the resource or is in the process of requesting it. In both cases, the resource request is terminated with the indication of a busy resource via internal flag. This implements the policy of no preemption.
3. If the μST line is not active, then the user:
 - a. Activates its μRQ line (μO output on the AmZ8000) and,
 - b. Waits for a finite delay (the AmZ8000 CPU MREQ instruction computes the delay by decrementing a 16-bit register). The delay is required in the case of several users requesting access to a particular resource. In this case, the daisy chain link lines (μAI , μAO) in the resource arbitration logic resolves the conflict by granting the resource to the highest priority requestor.
 - c. Tests the μAI – if active, then the resource is granted (the AmZ8000 again sets an internal flag); otherwise, the request is terminated.

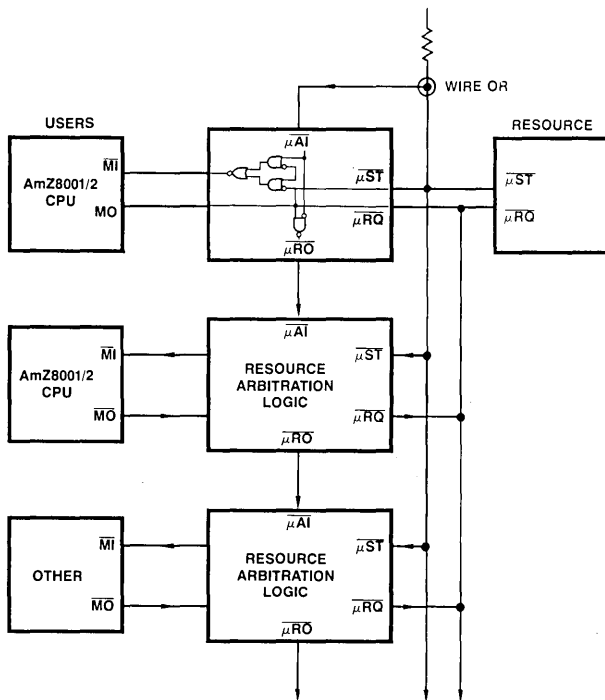

Figure 7. Multimicro Resource Daisy Sharing Chain Link.

Bus Request Chain Protocol

Typical data bus transactions follow a master/slave protocol between the AmZ8000 CPU and its peripherals. The CPU is the default bus master and does not require arbitration to access the bus. Some complex peripherals, like the AmZ8016 DMA, may require to obtain bus mastership in order to perform more complex bus transactions than the typical peripheral.

A Bus Request protocol is easily implemented to orderly request the AmZ8000 CPU to grant its bus mastership to one of several peripherals capable of commanding the bus. A daisy chain link priority resolution among bus requestors, along with a bus request protocol, forms an efficient bus mastership transfer. As common to most microcomputers, the AmZ8000 CPU recognizes asynchronous bus requests on its BUSRQ input pin, and grants it upon completion of the current machine cycle by causing its address/data, control and status outputs to go to high impedance and its BUSAK output pin to become active.

The algorithm for bus priority and request for bus requestors is as follows:

1. The requestor looks at its BRQ line to see if it is active. The BRQ line is bidirectional.
2. If the BRQ line is active, then the requestor waits. This implements the policy of non-preemption, since another peripheral could be in process of using or requesting the bus.
3. If the BRQ line is inactive, then the requestor activates its BRQ output and waits for its BAI input to go active. Upon BAI active, the requestor deactivates its BAO output (as opposed to letting the BAI input to ripple-thru to the BAO output), and takes control of the bus.

It is easy to see how the daisy chain link among peripherals is implemented to determine peripheral bus mastership priority.

Typical System Structures

The complexity of an AmZ8000 system mainly depends on the application and the needs of the user. Interface peripheral and memory devices can vary widely upon this complexity. At various stages of complexity, different types of system interface logic must be used depending on the loading requirements. A minimum AmZ8002 system is shown in Figure 9. The AmZ8002 CPU can drive one standard TTL load. An AmZ8127 clock generator is used to provide the system clock. Since the address and data are multiplexed together, an AmZ8173 octal latch is used to latch the addresses. Status is decoded by a Am74LS139 decoder. If loading exceeds one TTL load, buffers should be used as in Figure 10. On the data bus, two AmZ8104s are used to provide 16 bidirectional data lines. While an AmZ8144 buffer is used to give extra fan-out to the control signals. Direct addressing is available up to 64K bytes.

In Figure 11, an AmZ8001 segmented CPU is shown with the AmZ8010 Memory Management Unit. The AmZ8010 extends the memory into 64 segments where each segment can vary between 256 to 64K bytes. Without the AmZ8010, the AmZ8001 CPU can only access 8M bytes directly. This example can drive only TTL load. More drive capability could be added as in Figure 12. The buffering example is the same as Figure 11 with the exception of the AmZ8010 and the AmZ8144 to buffer the segment addresses.

AmZ8001

16-Bit Microprocessor

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

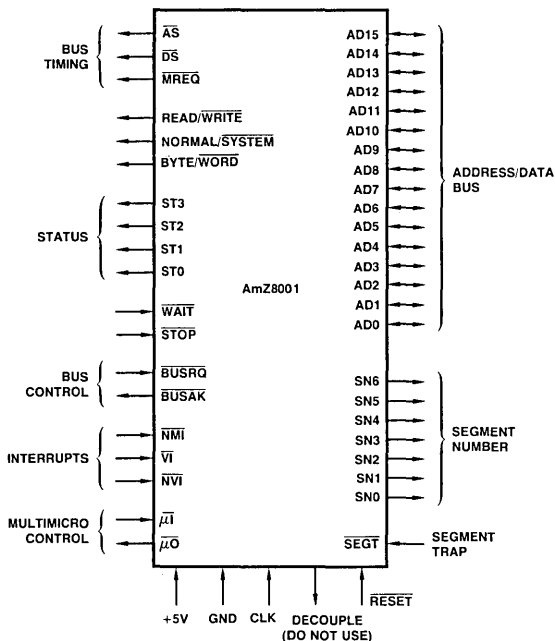

- Sixteen general purpose registers
- Direct addressing up to 8MB segmented memory
- Software compatible with AmZ8002 microprocessor
- Powerful instructions with flexible addressing modes
- Privileged/Non-Privileged mode of operation
- Sophisticated interrupt structure
- On-chip memory refresh facility
- TTL compatible inputs and outputs
- Single phase clock
- Single +5V power supply
- 48-pin package

GENERAL DESCRIPTION

The AmZ8001 is a general-purpose 16-bit CPU belonging to the AmZ8000 family of microprocessors. Its architecture is centered around sixteen 16-bit general registers. The CPU deals with 23-bit address spaces and hence can address directly 8MB of memory. The 23-bit address consists of two components: 7-bit segment number and 16-bit offset. Facilities are provided to maintain three distinct address spaces – code, data and stack. The AmZ8001 implements a powerful instruction set with flexible addressing modes. These instructions operate on several data types – bit, byte, word (16-bit), long word (32-bit), byte string and word string. The CPU can execute instructions in one of two modes – System and Normal. Sometimes these modes are also known as Privileged and Non-Privileged, respectively. The CPU also contains an on-chip memory refresh facility. The AmZ8001 is software compatible with the AmZ8002 microprocessor. The AmZ8001 is fabricated using silicon-gate N-MOS technology and is packaged in a 48-pin DIP. The AmZ8001 requires a single +5 power supply and a single phase clock for its operation.

INTERFACE SIGNAL DESCRIPTION**V_{CC}**: +5V Power Supply**V_{SS}**: Ground**AD0-AD15: Address/Data Bus (Bidirectional, 3-State)**

This 16-bit multiplexed address/data bus is used for all I/O and memory transactions. HIGH on the bus corresponds to 1 and LOW corresponds to 0. AD0 is the least significant bit position with AD15 is most significant. The \overline{AS} output and \overline{DS} output will indicate whether the bus is used for address offset or data. The status output lines ST0-ST3 will indicate the type of transaction; memory or I/O.

 \overline{AS} : Address Strobe (Output, 3-State)

LOW on this output indicates that the AD0-AD15 bus contains address information. The address information is stable by the time of the LOW-to-HIGH transition of the \overline{AS} output (see timing diagrams). The status outputs ST0-ST3 indicate whether the bus contains a memory address or I/O address.

 \overline{DS} : Data Strobe (Output, 3-State)

LOW on this output indicates that the AD0-AD15 bus is being used for data transfer. The R/\overline{W} output indicates the direction of data transfer – read (or in) means data into the CPU and write (or out) means data from the CPU. During a read operation, data can be gated on to the bus when \overline{DS} goes LOW. A LOW-to-HIGH transition on the \overline{DS} output indicates that the CPU has accepted the data (see timing diagram). During a write operation, LOW on the \overline{DS} output indicates that data is setup on the bus. Data will be removed sometime after the LOW-to-HIGH transition of the \overline{DS} output (see timing diagram).

 R/\overline{W} : Read/Write (Output, 3-State)

This output indicates the direction of data flow on the AD0-AD15 bus. HIGH indicates a read operation, i.e., data into the CPU and LOW indicates a write operation, i.e., data from the CPU. This output is activated at the same time as \overline{AS} going LOW and remains stable for the duration of the whole transaction (see timing diagram).

 B/\overline{W} : Byte/Word (Output, 3-State)

This output indicates the type of data transferred on the AD0-AD15 bus. HIGH indicates byte (8-bit) and LOW indicates word (16-bit) transfer. This output is activated at the same stage as \overline{AS} going LOW and remains valid for the duration of the whole transaction (see timing diagram). The address generated by the CPU is always a byte address. However, the memory is organized as 16-bit words. All instructions and word operands are word aligned and are addressed by even addresses. Thus, for all word transactions with the memory the least significant address bit will be zero. When addressing the memory for byte transactions, the least significant address bit determines which byte of the memory word is needed; even address specifies the most significant byte and odd address specifies the least significant byte. In the case of I/O transactions, the address information on the AD0-AD15 bus refers to an I/O port and B/\overline{W} determines whether a data word or data byte will be transacted. During I/O byte transactions, the least significant address bit A0 determines which half of the AD0-AD15 bus will be used for the I/O transactions. The ST0-ST3 outputs will indicate whether the current transaction is for memory, normal I/O or special I/O.

ST0-ST3: Status (Outputs, 3-State)

These four outputs contain information regarding the current transaction in a coded form. The status line codes are shown in the following table:

ST3	ST2	ST1	ST0	
L	L	L	L	Internal Operation
L	L	L	H	Memory Refresh
L	L	H	L	Normal I/O Transaction
L	L	H	H	Special I/O Transaction
L	H	L	L	Segment Trap Acknowledge
L	H	L	H	Non-Maskable Interrupt Acknowledge
L	H	H	L	Non-Vectored Interrupt Acknowledge
L	H	H	H	Vectored Interrupt Acknowledge
H	L	L	L	Memory Transaction for Operand
H	L	L	H	Memory Transaction for Stack
H	L	H	L	Reserved
H	L	H	H	Reserved
H	H	L	L	Memory Transaction for Instruction Fetch (Subsequent Word)
H	H	L	H	Memory Transaction for Instruction Fetch (First Word)
H	H	H	L	Reserved
H	H	H	H	Reserved

 \overline{WAIT} : Wait (Input)

LOW on this input indicates to the CPU that memory or I/O is not ready for the data transfer and hence the current transaction should be stretched. The \overline{WAIT} input is sampled by the CPU at certain instances during the transaction (see timing diagram). If \overline{WAIT} input is LOW at these instances, the CPU will go into wait state to prolong the transaction. The wait state will repeat until the \overline{WAIT} input is HIGH at the sampling instant.

 N/\overline{S} : Normal/System Mode (Output, 3-State)

HIGH on this output indicates that the CPU is operating in Normal Mode and LOW indicates operation in System Mode. This output is derived from the Flag Control Word (FCW) register. The FCW register is described under the program status information section of this document.

 \overline{MREQ} : Memory Request (Output, 3-State)

LOW on this output indicates that a CPU transaction with memory is taking place.

 \overline{BUSRQ} : Bus Request (Input)

LOW on this input indicates to the CPU that another device (such as DMA) is requesting to take control of the bus. The \overline{BUSRQ} input can be driven LOW anytime. The CPU synchronizes this input internally. The CPU responds by activating \overline{BUSAK} output LOW to indicate that the bus has been relinquished. Relinquishing the bus means that the AD0-AD15, \overline{AS} , \overline{DS} , B/\overline{W} , R/\overline{W} , N/\overline{S} , ST0-ST3, SN0-SN6 and \overline{MREQ} outputs will be in the high impedance state. The requesting device should control these lines in an identical fashion to the CPU to accomplish transactions. The \overline{BUSRQ} input must remain LOW as long as needed to perform all the transactions and the CPU will keep the \overline{BUSAK} output LOW. After completing the transactions, the device must disable the AD0-AD15, \overline{AS} , \overline{DS} , B/\overline{W} , R/\overline{W} , N/\overline{S} , ST0-ST3, SN0-SN6 and \overline{MREQ} into the high impedance state and stop driving the \overline{BUSRQ} input LOW. The CPU will make \overline{BUSAK} output HIGH sometime later and take back the bus control.

 \overline{BUSAK} : Bus Acknowledge (Output)

LOW on this output indicates that the CPU has relinquished the bus in response to a bus request.

NMI: Non-Maskable Interrupt (Input)

HIGH to LOW transition on this input constitutes non-maskable interrupt request. The CPU will respond with the Non-maskable Interrupt Acknowledge on the ST0-ST3 outputs and will enter an interrupt sequence. The transition on the NMI can occur anytime. Of the three kinds of interrupts available, the non-maskable interrupt has the highest priority.

VI: Vectored Interrupt (Input)

LOW on this input constitutes vectored interrupt request. Vectored interrupt is next lower to the non-maskable interrupt in priority. The VIE bit in the Flag and Control Word register must be 1 for the vectored interrupt to be honored. The CPU will respond with Vectored Interrupt Acknowledge code on the ST0-ST3 outputs and will begin the interrupt sequence. The VI input can be driven LOW anytime and should be held LOW until acknowledged.

NVI: Non-Vectored Interrupt (Input)

LOW on this input constitutes non-vectored interrupt request. Non-vectored has the lowest priority of the three types of interrupts. The NVIE bit in the Flag and Control Word register must be 1 for this request to be honored. The CPU will respond with Non-Vectored Interrupt Acknowledge code on the ST0-ST3 outputs and will begin the interrupt sequence. The NVI input can be driven LOW anytime and should be held LOW until acknowledged.

 μ I: Micro-In (Input)

This input participates in the resource request daisy chain. See the section on multimicroprocessor support facilities in this document.

 μ O: Micro-Out (Output)

This output participates in the resource request daisy chain. See the section on multimicroprocessor support facilities in this document.

RESET: Reset (Input)

LOW on this input initiates a reset sequence in the CPU. See the section on Initialization for details on reset sequence.

CLK: Clock (Input)

All CPU operations are controlled from the signal fed into this input. See DC characteristics for clock voltage level requirements.

DECOUPLE: (Output)

Output from the on-chip substrate bias generator. Do not use.

STOP: Stop (Input)

This active LOW input facilitates one instruction at a time operation. See the section on single stepping.

SN0-SN6: Segment Number (Outputs, 3-State)

These seven outputs contain the segment number part of a memory address. A HIGH on the output corresponds to 1 and a LOW corresponds to 0. SN0 is the least significant bit position and SN6 is the most significant bit position.

SEGT: Segment Trap (Input)

LOW on this input constitutes a segment trap request. If the line is driven LOW, the CPU will respond with the Segment Trap Acknowledge code on the Status lines, and commence a trap sequence. The SEGT input may be driven LOW at any time and is customarily held LOW until acknowledged. This input has priority over the interrupts.

PROCESSOR ORGANIZATION

The following is a brief discussion of the AmZ8001 CPU. For detailed information, see the AmZ8001/AmZ8002 Processor Instruction Set Manual (Publication No. AM-PUB086).

GENERAL PURPOSE REGISTERS

The CPU is organized around sixteen 16-bit general purpose registers R0 through R15 as shown in Figure 1. For byte operations, the first eight registers (R0 through R7) can also be addressed as sixteen 8-bit registers designated as RL0, RH0 and so on to RL7 and RH7. The sixteen registers can also be grouped in pairs RR0, RR2 and so on to RR14 to form eight long word (32-bit) registers. Similarly, the sixteen registers can be grouped in quadruples RQ0, RQ4, RQ8 and RQ12 to form four 64-bit registers.

Figure 1. AmZ8001 General Registers.

MOS-242

STACK POINTER

The AmZ8001 architecture allows stacks to be maintained in memory. Any general-purpose register pair except RR0 can be used as a stack pointer in stack manipulating instructions such as PUSH and POP. The designated register pair holds a 23-bit segmented address. Certain instructions (such as subroutine call and return) make implicit use of the register pair RR14 as the stack pointer. Two implicit stacks are allowed – normal stack using RR14 as the stack pointer, and system stack using RR14' as the system stack pointer (see Figure 1). If the CPU is operating in the Normal Mode, RR14 is active, and if the CPU is in System Mode, RR14' will be used instead of RR14. The implied stack pointer is a part of the general registers and hence can be manipulated using the instructions available for register operations.

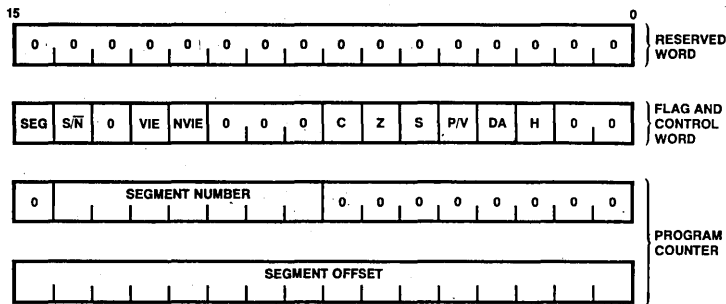

Figure 2. AmZ8001 Processor Status.

MOS-243

PROCESSOR STATUS

The CPU status consists of the 16-bit flag and control word (FCW) register, and the 23-bit program counter (see Figure 2). A reserved word is also included for future expansion. The following is a brief description of the FCW bits.

- SEG:** Segmented/Non-Segmented Bit. Indicates whether the AmZ8001 is running in segmented or non-segmented mode. 1 indicates segmented, 0 indicates non-segmented. See the section on non-segmented mode, elsewhere in this document.
- S/N:** System/Normal – 1 indicates System Mode and 0 indicates Normal Mode.
- VIE:** Vectored Interrupt Enable – 1 indicates that Vectored Interrupt requests will be honored.
- NVIE:** Non-Vectored Interrupt Enable – 1 indicates that Non-vectored interrupt requests will be honored.
- C:** Carry – 1 indicates that a carry has occurred from the most significant bit position when performing arithmetic operations.
- Z:** Zero – 1 indicates that the result of an operation is zero.
- S:** Sign – 1 indicates that the result of an operation is negative i.e., most significant bit is one.
- P/V:** Parity/Overflow – 1 indicates that there was an overflow during arithmetic operations. For byte logical operations this bit indicates parity of the result.
- DA:** Decimal Adjust – Records byte arithmetic operations.
- H:** Half Carry – 1 indicates that there was a carry from the most significant bit of the lower digit during byte arithmetic.

DATA TYPES

The AmZ8001 instructions operate on bits, digits (4 bits), bytes (8 bits), words (16 bits), long words (32 bits), byte strings and word strings type operands. Bits can be set, reset or tested. Digits are used to facilitate BCD arithmetic operations. Bytes are used for characters and small integers. Words are used for integer values and addresses while long words are used for large integer values and addresses. All operands except strings can reside either in memory or general registers. Strings can reside in memory only.

INTERRUPT AND TRAP STRUCTURE

Interrupt is defined as an external asynchronous event requiring program interruption. For example, interruption is caused by a peripheral needing service. Traps are synchronous events resulting from execution of certain instructions under some defined circumstances. Both interrupts and traps are handled in a similar manner by the AmZ8001.

The AmZ8001 supports three types of interrupts in order of descending priority – non-maskable, vectored and non-vectored.

The vectored and non-vectored interrupts can be disabled by appropriate control bits in the FCW. The AmZ8001 has four traps – system call, segment trap, unimplemented opcode and privileged instruction. The traps have higher priority than interrupts.

When an interrupt or trap occurs, the current program status is automatically pushed on to the system stack. The program status consists of processor status (i.e., PC and FCW) plus a 16-bit identifier. The identifier contains the reason, source and other coded information relating to the interrupt or trap.

After saving the current program status, the new processor status is automatically loaded from the new program status area located in the memory. This area is designated by the New Program Status Area Pointer (NPSAP) register. See AM-PUB086 publication for further details.

SEGMENTED ADDRESSING

The AmZ8001 can directly address up to 8MB of memory space, using a 23-bit segmented address. The memory space is divided up into 128 segments, each up to 64KB in size. The upper seven bits of address designate the segment number, and are available on the SN0-SN6 outputs during a memory transaction. See the section on memory transactions for details.

The lower sixteen bits of address designate an offset within the segment, relative to the start of the segment, and are available on AD0-AD15 during part of the memory transaction. See the section on memory transactions for details.

The segmented address may be stored as a long word in memory, or in a register pair. The segment number and offset can be manipulated separately or together, by suitable use of the instruction set.

When the segmented address is contained in code space, a short offset format may be adopted. The segmented address is stored as one word, seven bits of segment number and eight bits of offset. Figure 3 shows the format for segmented addresses.

ADDRESSING MODES

Information contained in the AmZ8001 instructions consists of the operation to be performed, the operand type and the location of the operands. Operand locations are designated by general register addresses, memory addresses or I/O addresses. The addressing mode of a given instruction defines the address space referenced and the method to compute the operand address. Addressing modes are explicitly specified or implied in an instruction. Figure 4 illustrates the eight explicit addressing modes: Register (R), Immediate (IM), Indirect Register (IR), Direct Address (DA), Indexed (X), Relative Address (RA), Base Address (BA) and Base Indexed (BX).

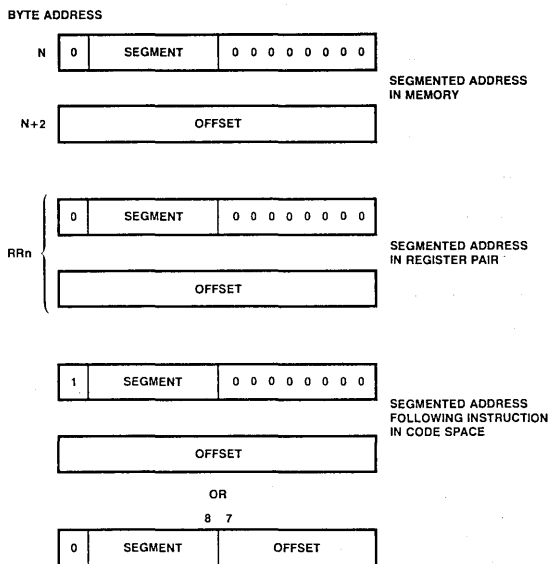

Figure 3. Segmented Address Formats.

MOS-244

When an effective segmented address is being computed according to the designated addressing mode, the segment number is not affected by any carry from the 16-bit offset.

NON-SEGMENTED MODE ON THE AmZ8001

The AmZ8001 can execute code designed to run on the non-segmented AmZ8002. This is achieved by changing the mode of execution of the AmZ8001 from segmented to non-segmented by writing a 0 to the SEG bit in the FCW. (See the section on processor status.) The change to non-segmented mode sets up a suitable environment for running non-segmented code. However, this environment only exists within the code segment that caused the change of mode from segmented to non-segmented.

SN0-SN6 will continue to indicate the code segment until a reset, interruption or return to segmented mode is encountered.

The effects of the non-segmented mode of operation on the AmZ8001 are described below.

- The AmZ8001 will interpret instruction length as if it was a non-segmented AmZ8002.
- The AmZ8001 will implement address computation in an identical manner to the AmZ8002.

Other CPU functions, such as interrupt and trap handling, reset and stack pointer manipulation are unaltered. These functions are characterized by the type of CPU, not by the state of the SEG bit in the FCW.

INPUT/OUTPUT

A set of I/O instructions are provided to accomplish byte or word transfers between the AmZ8001 and I/O devices. I/O devices are addressed using 16-bit I/O port addresses and I/O address space is not a part of the memory address space. Two types of I/O instructions are provided; each with its own 16-bit address space. I/O instructions include a comprehensive set of In, Out and Block transfers.

CPU TIMING

The AmZ8001 accomplishes instruction execution by stepping through a pre-determined sequence of machine cycles, such as memory read, memory write, etc. Each machine cycle requires between three and ten clock cycles. Bus Requests by DMA devices are granted at machine cycle boundaries. No machine cycle is longer than ten clock cycles; thus assuring fast response to a Bus Request (assuming no extra wait states). The start of a machine cycle is always marked by a LOW pulse on the \overline{AS} output. The status output lines ST0-ST3 indicate the nature of the current cycle in a coded form.

STATUS LINE CODES

Status line coding was listed in the table shown under ST0-ST3 outputs in the Interface Signal Description. The following is a detailed description of the status codes.

Internal Operation:

This status code indicates that the AmZ8001 is going through a machine cycle for its internal operation. Figure 5 depicts an internal operation cycle. It consists of three clock periods identified as T1, T2 and T3. The \overline{AS} output will be activated with a LOW pulse by the AmZ8001 to mark the start of a machine cycle. The ST0-ST3 will reflect the code for the internal operation. The \overline{MREQ} , \overline{DS} and R/W outputs will be HIGH. The N/S and SN0-SN6 outputs will remain at the same level as in the previous machine cycle. The AmZ8001 will ignore the \overline{WAIT} input during the internal operation cycle. The CPU will drive the AD0-AD15 bus with unspecified information during T1. However, the bus will go into high impedance during T2 and remain in that state for the remainder of the cycle. The B/W output is also activated by the CPU with unspecified information.

Memory Refresh:

This status code indicates that AmZ8001 is accessing the memory to refresh. The refresh cycle consists of three clock periods as depicted in Figure 6. The CPU will activate the \overline{AS} output with a LOW pulse to mark the beginning of a machine cycle and ST0-ST3 outputs will reflect the refresh cycle code. The least significant 9 lines of the AD0-AD15 bus contain the refresh address. Because the memory is word organized, AD0 will always be LOW. The most significant 7 bus lines are not specified. The \overline{DS} output will remain HIGH for the entire cycle while R/W, B/W, SN0-SN6 and N/S outputs will remain at the same level as in the machine cycle prior to refresh. The AD0-AD15 bus will go into high impedance state during T2 period and remain there for the remainder of the cycle. The AmZ8001 will activate the \overline{MREQ} output LOW during the refresh cycle. It should be noted that \overline{WAIT} input is ignored by the CPU for refresh operations.

I/O Transactions:

There are two status line codes used for I/O transaction cycles. The AmZ8001 provides two separate I/O spaces and two types of instructions called Normal I/O and Special I/O. Each I/O space is addressed by a 16-bit address called port address. The timing for both types of I/O transactions is essentially identical. A typical I/O cycle consists of four clock periods T1, T2, TWA and T3 as shown in Figure 7. The TWA is the wait state; insertion of one wait state for an I/O cycle is always automatic. Additional wait cycles can be inserted by LOW on the \overline{WAIT} input. The \overline{WAIT} input is sampled during every TW state. If this input is LOW, one more wait state will be inserted. Insertion of wait states continues until \overline{WAIT} input is HIGH. T3 state will follow the last wait state to complete the I/O cycle.

4

Mode	Operand Addressing		Operand Value	
	In the Instruction	In a Register		In Memory
Register	REGISTER ADDRESS	OPERAND	The content of the register.	
Immediate	OPERAND		In the instruction	
Indirect Register	REGISTER ADDRESS	ADDRESS	OPERAND	The content of the location whose address is in the register.
Direct Address	ADDRESS		OPERAND	The content of the location whose address is in the instruction.
Index	REGISTER ADDRESS BASE ADDRESS	DISPLACEMENT	OPERAND	The content of the location whose address is the address in the instruction, offset by the content of the working register.
Relative Address	DISPLACEMENT	PC VALUE	OPERAND	The content of the location whose address is the content of the program counter, offset by the displacement in the instruction.
Base Address	REGISTER ADDRESS DISPLACEMENT	BASE ADDRESS	OPERAND	The content of the location whose address is the address in the register, offset by the displacement in the instruction.
Base Index	REGISTER ADDRESS REGISTER ADDRESS	BASE ADDRESS DISPLACEMENT	OPERAND	The content of the location whose address is the address in the register, offset by the displacement in the register.

Figure 4. Addressing Modes.

MOS-245

During I/O cycles the ST0-ST3 outputs will reflect appropriate code depending on the type of instruction being executed (Normal I/O or Special I/O). \overline{AS} output will be pulsed LOW to mark the beginning of the cycle. The CPU drives the AD0-AD15 bus with the 16-bit port address specified by the current instruction. The $\overline{N/S}$ output will be LOW indicating that CPU is operating in the system mode. It should be recalled that the $\overline{N/S}$ output is derived from the appropriate bit in the FCW register. All I/O instructions are privileged instructions and will be allowed to execute only if the FCW specifies system mode operation. The \overline{MREQ} output will be HIGH. The AmZ8001 I/O instructions provide both word or byte transactions. The $\overline{B/W}$ output will be HIGH or LOW depending whether the instruction specifies a

byte or word transfer. The SN0-SN6 output will remain at the same level as in the machine cycle prior to the I/O cycle.

Two kinds of I/O transfers should be considered: Data In means reading from the device and Data Out means writing into the device. For In operations, the $\overline{R/W}$ output will be HIGH. The AD0-AD15 bus will go into high impedance state during T2. During byte input instructions, the CPU reads either the even or odd half of the Data Bus dependent upon the port address. If the port address is even, the most significant half of the Data Bus is read. If the port address is odd, the least significant half of the Data Bus is read. During word input instructions, the CPU reads all 16 bits of the Data Bus. The AmZ8001 will drive the DS

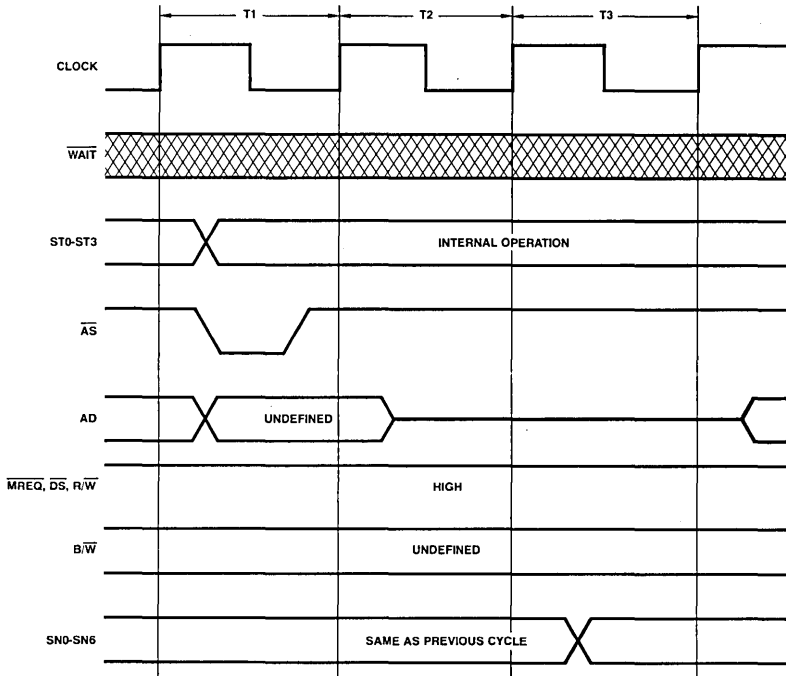

Figure 5. Internal Operation Cycle.

MOS-246

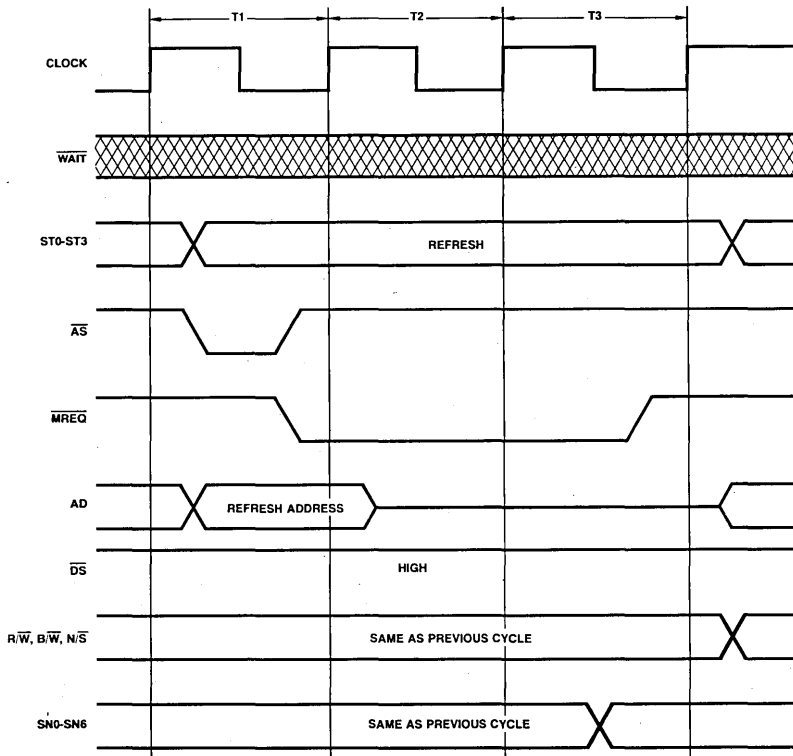

Figure 6. Refresh Cycle.

MOS-247

Figure 7. AmZ8001 I/O Cycle.

output LOW to signal to the device that data can be gated on to the bus. The CPU will accept the data during T3 and \overline{DS} output will go HIGH signalling the end of an I/O transaction.

For Data Out, the $\overline{R/\overline{W}}$ output will be LOW. The AmZ8001 will provide data on the AD0-AD15 bus and activates the \overline{DS} output LOW during T2. During byte output instructions, the CPU duplicates the byte data onto both the high and low halves of the Data Bus and external logic, using A0, enables the appropriate byte port. During word output instructions the CPU outputs data onto all 16 bits of the Data Bus. The \overline{DS} output goes HIGH during T3 and the cycle is complete.

Memory Transactions:

There are four status line codes that indicate a memory transaction:

- Memory transaction to read or write an operand
- Memory transaction to read from or write into the stack

- Memory transaction to fetch the first word of an instruction (sometimes called IF1)
- Memory transaction to fetch the subsequent word of an instruction (sometimes called IFN).

It can be appreciated that all the above transactions essentially fall into two categories: memory read and memory write. In the case of IF1 and IFN cycles, the memory will be read at the address supplied by the program counter. All AmZ8001 instructions are multiples of 16-bit words. Words are always addressed by an even address. Thus IF1 and IFN cycles involve performing a memory read for words. On the other hand, a memory transaction for operand and stack operation could be a read or write. Moreover, an operand could be a word or a byte. For stack operation involving the implied stack pointer the address will be supplied by the RR14 (or RR14'). For operand transactions, the memory address will come from several sources depending on the instruction and the addressing mode. Memory transaction cycle timing is shown in Figure 8. It typically consists of three clock periods T1, T2 and T3. Wait states (TW) can be inserted

Figure 8. Memory Transactions.

MOS-249

between T2 and T3 by activating the $\overline{\text{WAIT}}$ input LOW. The $\overline{\text{WAIT}}$ input will be sampled during T2 and during every subsequent TW. The ST0-ST3 outputs will reflect the appropriate code for the current cycle early in T1 and the $\overline{\text{AS}}$ output will be pulsed LOW to mark the beginning of the cycle. The N/S output will indicate whether the normal or system address space will be used for the current cycle. As shown in the figure the MREQ output will go LOW during T1 to indicate a memory operation.

The segment number becomes valid on the segment lines one clock period before the start of the memory operation, and remains valid until the start of T3.

Consider a read operation first. The $\overline{\text{R/W}}$ output will be HIGH. The AmZ8001 will drive the AD0-AD15 with the appropriate address early in T1. During T2, the bus will go into high-impedance state and $\overline{\text{DS}}$ output will be activated LOW by the CPU. The data can be gated on to the bus when $\overline{\text{DS}}$ is LOW. During T1 the $\overline{\text{B/W}}$ will also be activated to indicate byte or word will be transacted. The AmZ8001 memory is word organized and words are addressed by even addresses. However, when addressing bytes, the memory address may be odd or even; an even address for most significant byte of a word and the next odd address for the least significant byte of that word. When reading a byte from the memory, the least significant address bit can be ignored and the whole word containing the desired byte is gated on to the bus. The CPU will pick the appropriate byte automatically. The AmZ8001 will drive the $\overline{\text{DS}}$ output HIGH indicating data acceptance.

Consider the write operation next. The $\overline{\text{R/W}}$ output will be LOW. The AmZ8001 removes the address and gates out the data to be written on the bus and activates the $\overline{\text{DS}}$ output LOW during T2. If the data to be written is a byte then the same byte will be on both halves of the bus. The $\overline{\text{DS}}$ output will go HIGH during T3 signifying completion of the cycle.

Interrupt and Segment Trap Acknowledge:

There are four status line codes devoted to interrupt and trap acknowledgement. These correspond to non-maskable, vectored and non-vectored interrupts, as well as segment trap. The Interrupt Acknowledge cycle is illustrated in Figure 9. The NMI input of the AmZ8001 is edge detected i.e., a HIGH to LOW input level change is stored in an internal latch. Similar internal storage is not provided for the $\overline{\text{VI}}$, $\overline{\text{NVI}}$, and $\overline{\text{SEGT}}$ inputs. For $\overline{\text{VI}}$ and $\overline{\text{NVI}}$ inputs to cause an interruption, the corresponding interrupt enable bits in the FCW must be 1. For the following discussion, both the VIE and NVIE bits in the FCW are assumed to be 1.

As shown in the figure, the $\overline{\text{VI}}$, $\overline{\text{NVI}}$ and $\overline{\text{SEGT}}$ input and the internal $\overline{\text{NMI}}$ latch output are sampled during T3 of the last machine cycle of an instruction.

A LOW on these signals triggers the corresponding interrupt acknowledge sequence described on the following page. The AmZ8001 executes a dummy IF1 cycle prior to entering the actual acknowledge cycle (see memory transactions for IF1 cycle description).

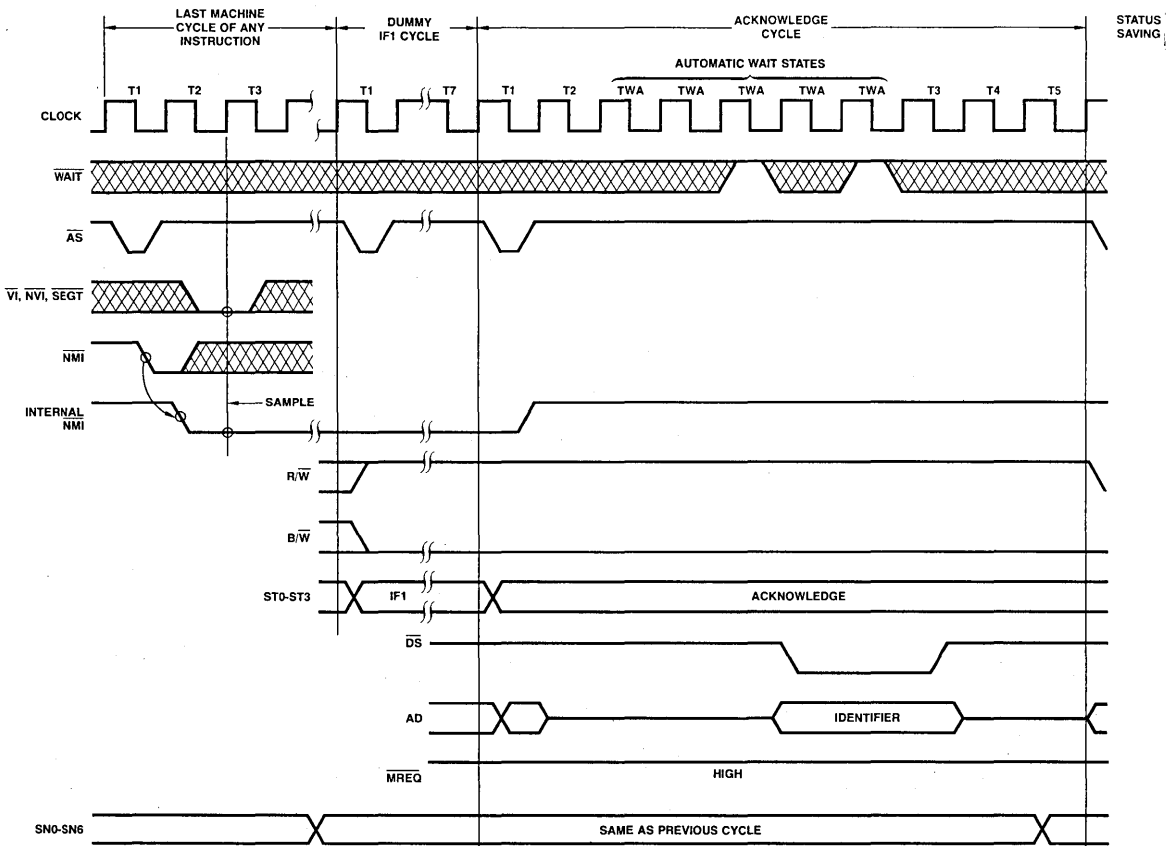

Figure 9. Interrupt Acknowledge Cycle.

During this dummy IF1 cycle, the program counter is not updated; instead the implied system stack pointer (RR14') will be decremented. Following the dummy IF1 cycle is the actual interrupt/trap acknowledge cycle.

The interrupt acknowledge cycle typically consists of 10 clock periods; T1 through T5 and five automatic TW (wait states). As usual, the \overline{AS} output will be pulsed LOW during T1 to mark the beginning of a cycle. The ST0-ST3 outputs will reflect the appropriate interrupt acknowledge code, the MREQ output will be HIGH, the $\overline{N/S}$ output remains the same as in the preceding cycle, the R/W output will be HIGH and the B/W output will be LOW. The AmZ8001 will drive the AD0-AD15 bus with unspecified information during T1 and the bus will go into the high impedance state during T2. Three TWA states will automatically follow T2. The WAIT input will be sampled during the third TWA state.

If LOW, an extra TW state will be inserted and the \overline{WAIT} will be sampled again during TW. Such insertion of TW states continues until the \overline{WAIT} input is HIGH. After the last TW state, the \overline{DS} output will go LOW and two more automatic wait states (TWA) follow. The interrupting device can gate up to a 16-bit identifier on to the bus when the \overline{DS} output is LOW. The \overline{WAIT} input will be sampled again during the last TWA state. If the \overline{WAIT} input is LOW one TW state will be inserted and the \overline{WAIT} will be sampled during TW. Such TW insertion continues until the \overline{WAIT} input is HIGH. After completing the last TW state T3 will be entered and the \overline{DS} output will go HIGH. The interrupting device should remove the identifier and cease driving the bus. T4 and T5 states will follow T3 to complete the cycle. Following

the interrupt acknowledge cycle will be memory transaction cycles to save the status on the stack. Note that the $\overline{N/S}$ output will be automatically LOW during status saving. The SN0-SN6 outputs are undefined during the acknowledge cycle.

The internal NMI latch will be reset to the initial state at \overline{AS} going HIGH in the interrupt acknowledge cycle. The \overline{VI} , \overline{NVI} and \overline{SEGT} input should be kept LOW until this time also.

STATUS SAVING SEQUENCE:

The machine cycles following the interrupt acknowledge cycle push the old status information on the system stack in the following order: program counter, the flag and control word and the interrupt/trap identifier. Subsequent machine cycles fetch the new program status from the new program status area, and then branch to the interrupt/service routine.

BUS REQUEST/BUS ACKNOWLEDGE TIMING:

A LOW on the \overline{BUSRQ} input is an indication to the AmZ8001 that another device (such as DMA) is requesting control of the bus. The \overline{BUSRQ} input is synchronized internally at T1 of any machine cycle. (See next paragraph for exception.) The \overline{BUSAK} will go LOW after the last clock period of the machine cycle. The LOW on the \overline{BUSAK} output indicates acknowledgement. When \overline{BUSAK} is LOW the following outputs will go into the high impedance state; AD0-AD15, \overline{AS} , \overline{DS} , MREQ, ST0-ST3, B/W, R/W, SN0-SN6 and $\overline{N/S}$. The \overline{BUSRQ} must be held LOW until all transactions are completed. When \overline{BUSRQ} goes HIGH, it is synchronized internally, the \overline{BUSAK} output will go HIGH and normal CPU operation will resume. Figure 10 illustrates the $\overline{BUSRQ}/\overline{BUSAK}$ timing.

4

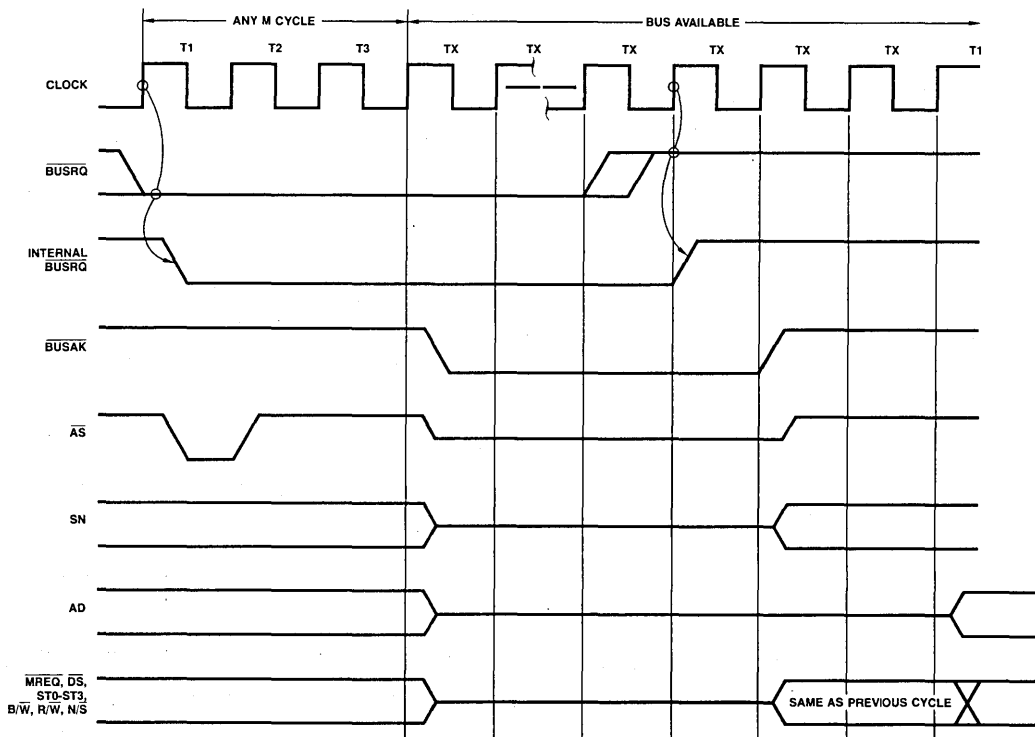

Figure 10. Bus Request/Acknowledge Cycle.

It was mentioned that $\overline{\text{BUSRQ}}$ will be honored during any machine cycle with one exception. This exception is during the execution of TSET/TSETB instructions. $\overline{\text{BUSRQ}}$ will not be honored once execution of these instructions has started.

SINGLE STEPPING

The $\overline{\text{STOP}}$ input of the AmZ8001 facilitates one instruction at a time or single step operation. Figure 11 illustrates $\overline{\text{STOP}}$ input timing. The $\overline{\text{STOP}}$ input is sampled on the HIGH to LOW transition of the clock input that immediately precedes an IF1 cycle. If the $\overline{\text{STOP}}$ is found LOW, AmZ8001 introduces a memory refresh cycle after T3. Moreover, $\overline{\text{STOP}}$ input will be sampled again at T3 in the refresh cycle. If $\overline{\text{STOP}}$ is LOW one more refresh cycle will follow the previous refresh cycle. The $\overline{\text{STOP}}$ will be sampled during T3 of the refresh cycle also. One additional refresh cycle will be added every time $\overline{\text{STOP}}$ input is sampled LOW. After completing the last refresh cycle which will occur after $\overline{\text{STOP}}$ is HIGH, the CPU will insert two dummy states T4 and T5 to complete the IF1 cycle and resume its normal operations for executing the instruction. See appropriate sections on memory transactions and memory refresh. It should be noted that refresh cycles will occur even if the refresh facility is disabled during single stepping.

MULTIMICROPROCESSOR FACILITIES

The AmZ8001 is provided with hardware and software facilities to support multiple microprocessor systems. The $\overline{\mu\text{O}}$ and $\overline{\mu\text{I}}$ signals of the AmZ8001 are used in conjunction with the MBIT, MREQ, MRES and MSET instructions for this purpose. The $\overline{\mu\text{O}}$ output can be activated LOW by using appropriate instruction to signal a request from the AmZ8001 for a resource. The $\overline{\mu\text{I}}$ input is tested by the AmZ8001 before activating the $\overline{\mu\text{O}}$ output. LOW at the $\overline{\mu\text{I}}$ input indicates that the resource is busy. The AmZ8001

can examine the $\overline{\mu\text{I}}$ input after activating the $\overline{\mu\text{O}}$ output LOW. The $\overline{\mu\text{I}}$ will be tested again to see if the requested resource became available. For detailed information on the Multimicroprocessor facilities, AmZ8001/AmZ8002 Processor Interface Manual (Publication No. AM-PUB089) should be consulted.

INITIALIZATION

A LOW on the $\overline{\text{Reset}}$ input starts the CPU initialization. The initialization sequence is shown in Figure 12. Within five clock periods after the HIGH to LOW level change of the $\overline{\text{Reset}}$ input the following will occur:

- a) AD0-AD15 bus will be in the HIGH impedance state
- b) $\overline{\text{AS}}$, $\overline{\text{DS}}$, MREQ, $\overline{\text{BUSAK}}$ and $\overline{\mu\text{O}}$ outputs will be HIGH
- c) ST0-ST3 outputs will be LOW
- d) Refresh will be disabled
- e) R/W, B/W and N/S outputs are not affected. For a power on reset the state of these outputs is not specified.
- f) SN0-SN6 outputs will be LOW.

After the $\overline{\text{Reset}}$ input returns HIGH and remains HIGH for three clock periods, three 16-bit memory read operations will be performed as follows from segment C. Note that the N/S output will be LOW and ST0-ST3 outputs will reflect IFN code.

- a) The contents of the memory location 0002 will be read. This information will be loaded into the FCW of the AmZ8001.
- b) The contents of the memory location 0004 will be read. This information will be loaded into the program counter segment number.
- c) The contents of the memory location 0006 will be read. This information will be loaded into the program counter offset.

This completes initialization sequence and an IF1 cycle will follow to fetch the first instruction to begin program execution. See the section on memory transactions for timing.

CPU CONTROL

Mne- monics	Operands	Addr. Modes	Operation
COMFLG	flags	-	Complement Flag (Any combination of C, Z, S, P/V)
DI*	int	-	Disable Interrupt (Any combination of NVI, VI)
EI*	int	-	Enable Interrupt (Any combination of NVI, VI)
HALT*	-	-	HALT
LDCTL*	CTLR, src	R	Load into Control Register $\text{CTLR} \leftarrow \text{src}$
LDCTL*	dst, CTLR	R	Load from Control Register $\text{dst} \leftarrow \text{CTLR}$
LDCTLB	FLGR, src	R	Load into Flag Byte Register $\text{FLGR} \leftarrow \text{src}$
LDCTLB	dst, FLGR	R	Load from Flag Byte Register $\text{dst} \leftarrow \text{FLGR}$
LDPS*	src	IR DA X	Load Program Status $\text{PS} \leftarrow \text{src}$
MBIT*	-	-	Test Multi-Micro Bit Set S if $\overline{\mu 1}$ is High; reset S if $\overline{\mu 1}$ is Low.
MREQ*	dst	R	Multi-Micro Request
MRES*	-	-	Multi-Micro Reset
MSET*	-	-	Multi-Micro Set
NOP	-	-	No Operation
RESFLG	flag	-	Reset Flag (Any combination of C, Z, S, P/V)
SETFLG	flag	-	Set Flag (Any combination of C, Z, S, P/V)

AC TIMING DIAGRAM

Timing measurements are made at the following voltages.

	HIGH	LOW
Clock	4.0V	0.8V
Output	2.0V	0.8V
Input	2.0V	0.8V
Float (ΔV)	$\pm 0.5V$	$\pm 0.5V$

This composite timing diagram does not show actual timing sequences. Refer to this diagram only for the detailed timing relationships of individual edges. Use the preceding illustrations as an explanation of the various timing sequences.

MAXIMUM RATINGS above which useful life may be impaired.

Voltages on all inputs and outputs with respect to GND	-0.3V to +7.0V
Operating Ambient Temperature	0 to +70°C
Storage Temperature	-65 to +150°C

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulations of static charge. It is suggested, nevertheless, that conventional precautions be observed during storage, handling and use in order to avoid exposure to excessive voltages.

ELECTRICAL CHARACTERISTICS over operating range (Note 1)

Parameter	Description	Test Conditions	Min	Max	Units

4

Standard Test Conditions

The characteristics below apply for the following standard test conditions, unless otherwise noted. All voltages are referenced to GND. Positive current flows into the referenced pin. Standard conditions are as follows:

$$+4.75V \leq V_{CC} \leq +5.25V$$

$$GND = 0V$$

$$0^{\circ}C \leq T_A \leq +70^{\circ}C$$

All AC parameters assume a load capacitance of 100pF max, except for parameter 6, T_{dC}(SNv) (50pF max). Timing references between two output signals assume a load difference of 50pF max.

AmZ8002

16-Bit Microprocessor

PRELIMINARY DATA

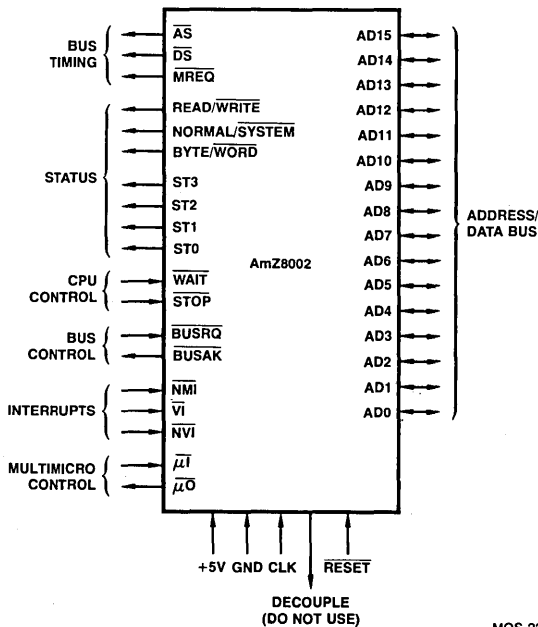

DISTINCTIVE CHARACTERISTICS

- Sixteen general purpose registers
- Direct addressing up to 64KB memory
- Software compatible with AmZ8001 microprocessor
- Powerful instructions with flexible addressing modes
- Privileged/Non-Privileged mode of operation
- Sophisticated interrupt structure
- On-chip memory refresh facility
- TTL compatible inputs and outputs
- Single phase clock
- Single +5V power supply
- 40-pin package

GENERAL DESCRIPTION

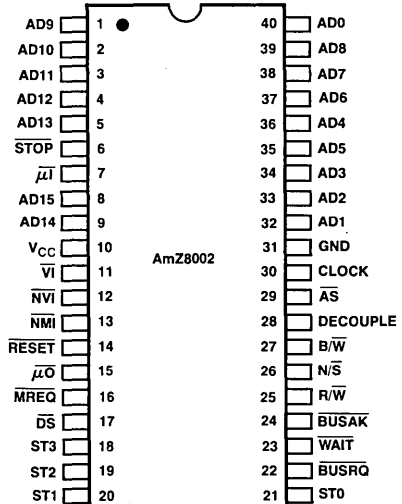

The AmZ8002 is a general-purpose 16-bit CPU belonging to the AmZ8000 family of microprocessors. Its architecture is centered around sixteen 16-bit general registers. The CPU deals with 16-bit address spaces and hence can address directly 64 Kilobytes of memory. Facilities are provided to maintain three distinct address spaces – code, data and stack. The AmZ8002 implements a powerful instruction set with flexible addressing modes. These instructions operate on several data types – bit, byte, word (16-bit), long word (32-bit), byte string and word string. The CPU can execute instructions in one of two modes – System and Normal. Sometimes these modes are also known as Privileged and Non-Privileged, respectively. The CPU also contains an on-chip memory refresh facility. The AmZ8002 is software compatible with the AmZ8001 microprocessor. The AmZ8002 is fabricated using silicon-gate N-MOS technology and is packaged in a 40-pin DIP. The AmZ8002 requires a single +5 power supply and a single phase clock for its operation.

INTERFACE SIGNAL DESCRIPTION

V_{CC} : +5V Power Supply

V_{SS} : Ground

AD0-AD15: Address/Data Bus (Bidirectional, 3-State)

This 16-bit multiplexed address/data bus is used for all I/O and memory transactions. HIGH on the bus corresponds to 1 and LOW corresponds to 0. AD0 is the least significant bit position with AD15 the most significant. The \overline{AS} output and \overline{DS} output will indicate whether the bus is used for address or data. The status output lines ST0-ST3 will indicate the type of transaction; memory or I/O.

 \overline{AS} : Address Strobe (Output, 3-State)

LOW on this output indicates that the AD0-AD15 bus contains address information. The address information is stable by the time of the LOW-to-HIGH transition of the \overline{AS} output (see timing diagrams). The status outputs ST0-ST3 indicate whether the bus contains a memory address or I/O address.

 \overline{DS} : Data Strobe (Output, 3-State)

LOW on this output indicates that the AD0-AD15 bus is being used for data transfer. The R/\overline{W} output indicates the direction of data transfer – read (or in) means data into the CPU and write (or out) means data from the CPU. During a read operation, data can be gated on to the bus when \overline{DS} goes LOW. A LOW-to-HIGH transition on the \overline{DS} output indicates that the CPU has accepted the data (see timing diagram). During a write operation, LOW on the \overline{DS} output indicates that data is setup on the bus. Data will be removed sometime after the LOW-to-HIGH transition of the \overline{DS} output (see timing diagram).

 R/\overline{W} : Read/Write (Output, 3-State)

This output indicates the direction of data flow on the AD0-AD15 bus. HIGH indicates a read operation, i.e., data into the CPU and LOW indicates a write operation, i.e., data from the CPU. This output is activated at the same time as \overline{AS} going LOW and remains stable for the duration of the whole transaction (see timing diagram).

 B/\overline{W} : Byte/Word (Output, 3-State)

This output indicates the type of data transferred on the AD0-AD15 bus. HIGH indicates byte (8-bit) and LOW indicates word (16-bit) transfer. This output is activated at the same stage as \overline{AS} going LOW and remains valid for the duration of the whole transaction (see timing diagram). The address generated by the CPU is always a byte address. However, the memory is organized as 16-bit words. All instructions and word operands are word aligned and are addressed by even addresses. Thus, for all word transactions with the memory the least significant address bit will be zero. When addressing the memory for byte transactions, the least significant address bit determines which byte of the memory word is needed; even address specifies the most significant byte and odd address specifies the least significant byte. In the case of I/O transactions, the address information on the AD0-AD15 bus refers to an I/O port and B/\overline{W} determines whether a data word or data byte will be transacted. During I/O byte transactions, the least significant address bit A0 determines which half of the AD0-AD15 bus will be used for the I/O transactions. The ST0-ST3 outputs will indicate whether the current transaction is for memory, normal I/O or special I/O.

ST0-ST3: Status (Outputs, 3-State)

These four outputs contain information regarding the current transaction in a coded form. The status line codes are shown in the following table:

ST3	ST2	ST1	ST0	
L	L	L	L	Internal Operation
L	L	L	H	Memory Refresh
L	L	H	L	Normal I/O Transaction
L	L	H	H	Special I/O Transaction
L	H	L	L	Reserved
L	H	L	H	Non-Maskable Interrupt Acknowledge
L	H	H	L	Non-Vectored Interrupt Acknowledge
L	H	H	H	Vectored Interrupt Acknowledge
H	L	L	L	Memory Transaction for Operand
H	L	L	H	Memory Transaction for Stack
H	L	H	L	Reserved
H	L	H	H	Reserved
H	H	L	L	Memory Transaction for Instruction Fetch (Subsequent Word)
H	H	L	H	Memory Transaction for Instruction Fetch (First Word)
H	H	H	L	Reserved
H	H	H	H	Reserved

 \overline{WAIT} : Wait (Input)

LOW on this input indicates to the CPU that memory or I/O is not ready for the data transfer and hence the current transaction should be stretched. The \overline{WAIT} input is sampled by the CPU at certain instances during the transaction (see timing diagram). If \overline{WAIT} input is LOW at these instances, the CPU will go into wait state to prolong the transaction. The wait state will repeat until the \overline{WAIT} input is HIGH at the sampling instant.

 N/\overline{S} : Normal/System Mode (Output, 3-State)

HIGH on this output indicates that the CPU is operating in Normal Mode and LOW indicates operation in System Mode. This output is derived from the Flag Control Word (FCW) register. The FCW register is described under the program status information section of this document.

 \overline{MREQ} : Memory Request (Output, 3-State)

LOW on this output indicates that a CPU transaction with memory is taking place.

 \overline{BUSRQ} : Bus Request (Input)

LOW on this input indicates to the CPU that another device (such as DMA) is requesting to take control of the bus. The \overline{BUSRQ} input can be driven LOW anytime. The CPU synchronizes this input internally. The CPU responds by activating \overline{BUSAK} output LOW to indicate that the bus has been relinquished. Relinquishing the bus means that the AD0-AD15, \overline{AS} , \overline{DS} , B/\overline{W} , R/\overline{W} , N/\overline{S} , ST0-ST3 and \overline{MREQ} outputs will be in the high impedance state. The requesting device should control these lines in an identical fashion to the CPU to accomplish transactions. The \overline{BUSRQ} input must remain LOW as long as needed to perform all the transactions and the CPU will keep the \overline{BUSAK} output LOW. After completing the transactions, the device must disable the AD0-AD15, \overline{AS} , \overline{DS} , B/\overline{W} , R/\overline{W} , N/\overline{S} , ST0-ST3 and \overline{MREQ} into the high impedance state and stop driving the \overline{BUSRQ} input LOW. The CPU will make \overline{BUSAK} output HIGH sometime later and take back the bus control.

 \overline{BUSAK} : Bus Acknowledge (Output)

LOW on this output indicates that the CPU has relinquished the bus in response to a bus request.

NMI: Non-Maskable Interrupt (Input)

HIGH-to-LOW transition on this input constitutes non-maskable interrupt request. The CPU will respond with the non-maskable Interrupt Acknowledge on the ST0-ST3 outputs and will enter an interrupt sequence. The transition on the NMI can occur anytime. Of the three kinds of interrupts available, the non-maskable interrupt has the highest priority.

VI: Vectored Interrupt (Input)

LOW on this input constitutes vectored interrupt request. Vectored interrupt is next lower to the non-maskable interrupt in priority. The VIE bit in the Flag and Control Word register must be 1 for the vectored interrupt to be honored. The CPU will respond with Vectored Interrupt Acknowledge code on the ST0-ST3 outputs and will begin the interrupt sequence. The VI input can be driven LOW any time and should be held LOW until acknowledged.

NVI: Non-Vectored Interrupt (Input)

LOW on this input constitutes non-vectored interrupt request. Non-vectored has the lowest priority of the three types of interrupts. The NVIE bit in the Flag and Control Word register must be 1 for this request to be honored. The CPU will respond with Non-Vectored Interrupt Acknowledge code on the ST0-ST3 outputs and will begin the interrupt sequence. The NVI input can be driven LOW anytime and should be held LOW until acknowledged.

μI: Micro-In (Input)

This input participates in the resource request daisy chain. See the section on multimicroprocessor support facilities in this document.

μO: Micro-Out (Output)

This output participates in the resource request daisy chain. See the section on multimicroprocessor support facilities in this document.

RESET: Reset (Input)

LOW on this input initiates a reset sequence in the CPU. See the section on Initialization for details on reset sequence.

CLK: Clock (Input)

All CPU operations are controlled from the signal fed into this input. See DC Characteristics for clock voltage level requirements.

DECOUPLE: (Output)

Output from the on-chip substrate bias generator. Do not use.

STOP: Stop (Input)

This active LOW input facilitates one instruction at a time operation. See the section on single stepping.

PROCESSOR ORGANIZATION

The following is a brief discussion of the AmZ8002 CPU. For detailed information, see the AmZ8001/AmZ8002 Processor Instruction Set Manual (Publication No. AM-PUB086).

General Purpose Registers

The CPU is organized around sixteen 16-bit general purpose registers R0 through R15 as shown in Figure 1. For byte operations, the first eight registers (R0 through R7) can also be addressed as sixteen 8-bit registers designated as RL0, RH0 and so on to RL7 and RH7. The sixteen registers can also be grouped in pairs RR0, RR2 and so on to RR14 to form eight long

Figure 1. AmZ8002 General Registers.

MOS-227

word (32-bit) registers. Similarly, the sixteen registers can be grouped in quadruples RQ0, RQ4, RQ8 and RQ12 to form four 64-bit registers.

STACK POINTER

The AmZ8002 architecture allows stacks to be maintained in the memory. Any general purpose register except R0 can be used as a stack pointer in stack manipulating instructions such as PUSH and POP. However, certain instructions such as subroutine call and return make implicit use of the register R15 as the stack pointer. Two implicit stacks are maintained - normal stack using R15 as the stack pointer and system stack using R15' as the system stack pointer (see Figure 1). If the CPU is operating in the Normal Mode, R15 is active, and if the CPU is in System Mode R15' will be used instead of R15. The implied stack pointer is a part of the general registers and hence can be manipulated using the instructions available for register operations.

PROCESSOR STATUS

The CPU status consists of the 16-bit Program Counter (PC) and the 16-bit Flag and Control Word (FCW) register (see Figure 2). The following is a brief description of the FCW bits.

- S/N**: System/Normal - 1 indicates System Mode and 0 indicates Normal Mode.
- VIE**: Vectored Interrupt Enable - 1 indicates that Vectored Interrupt requests will be honored.
- NVIE**: Non-Vectored Interrupt Enable - 1 indicates that non-vectored interrupt requests will be honored.
- C**: Carry - 1 indicates that a carry has occurred from the most significant bit position when performing arithmetic operations.
- Z**: Zero - 1 indicates that the result of an operation is zero.

Figure 2. AmZ8002 Processor Status.

MOS-228

- S:** Sign – 1 indicates that the result of an operation is negative i.e., most significant bit is one.
- P/V:** Parity/Overflow – 1 indicates that there was an overflow during arithmetic operations. For logical operations this bit indicates parity of the result.
- DA:** Decimal Adjust – Records byte arithmetic operations.
- H:** Half Carry – 1 indicates that there was a carry from the most significant bit of the lower digit during byte arithmetic.

DATA TYPES

The AmZ8002 instructions operate on bits, digits (4 bits), bytes (8 bits), words (16 bits), long words (32 bits), byte strings and word strings type operands. Bits can be set, reset or tested. Digits are used to facilitate BCD arithmetic operations. Bytes are used for characters and small integers. Words are used for integer values and addresses while long words are used for large integer values. All operands except strings can reside either in memory or general registers. Strings can reside in memory only.

INTERRUPT AND TRAP STRUCTURE

Interrupt is defined as an external asynchronous event requiring program interruption. For example, interruption is caused by a peripheral needing service. Traps are synchronous events resulting from execution of certain instructions under some defined circumstances. Both interrupts and traps are handled in a similar manner by the AmZ8002.

The AmZ8002 supports three types of interrupts in order of descending priority – non-maskable, vectored and non-vectored. The vectored and non-vectored interrupts can be disabled by appropriate control bits in the FCW. The AmZ8002 has three traps – system call, unimplemented opcode and privileged instruction. The traps have higher priority than interrupts.

When an interrupt or trap occurs, the current program status is automatically pushed on to the system stack. The program status consists of processor status (i.e., PC and FCW) plus a 16-bit identifier. The identifier contains the reason, source and other coded information relating to the interrupt or trap.

After saving the current program status, the new processor status is automatically loaded from the new program status area located in the memory. This area is designated by the New Program Status Area Pointer (NPSAP) register. See AM-PUB086 publication for further details.

ADDRESSING MODES

Information contained in the AmZ8002 instructions consists of the operation to be performed, the operand type and the location of the operands. Operand locations are designated by general register addresses, memory addresses or I/O addresses. The addressing mode of a given instruction defines the address space referenced and the method to compute the operand address. Addressing modes are explicitly specified or implied in an instruction. Figure 3 illustrates the eight explicit addressing modes: Register (R), Immediate (IM), Indirect Register (IR), Direct Address (DA), Indexed (X), Relative Address (RA), Base Address (BA) and Base Indexed (BX).

INPUT/OUTPUT

A set of I/O instructions are provided to accomplish byte or word transfers between the AmZ8002 and I/O devices. I/O devices are addressed using 16-bit I/O port addresses and I/O address space is not a part of the memory address space. Two types of I/O instructions are provided; each with its own 16-bit address space. I/O instructions include a comprehensive set of In, Out and Block transfers.

CPU TIMING

The AmZ8002 accomplishes instruction execution by stepping through a pre-determined sequence of machine cycles, such as memory read, memory write, etc. Each machine cycle requires between three and ten clock cycles. Bus Requests by DMA devices are granted at machine cycle boundaries. No machine cycle is longer than ten clock cycles; thus assuring fast response to a Bus Request (assuming no extra wait states). The start of a machine cycle is always marked by a LOW pulse on the \overline{AS} output. The status output lines ST0-ST3 indicate the nature of the current cycle in a coded form.

STATUS LINE CODES

Status line coding was listed in the table shown under ST0-ST3 outputs in the Interface Signal Description. The following is a detailed description of the status codes.

Internal Operation:

This status code indicates that the AmZ8002 is going through a machine cycle for its internal operation. Figure 4 depicts an internal operation cycle. It consists of three clock periods identified as T1, T2 and T3. The \overline{AS} output will be activated with a LOW pulse by the AmZ8002 to mark the start of a machine cycle. The ST0-ST3 will reflect the code for the internal operation. The \overline{MREQ} , \overline{DS} and R/W outputs will be HIGH. The N/S output will remain at the same level as in the previous machine cycle. The AmZ8002 will ignore the \overline{WAIT} input during the internal operation cycle. The CPU will drive the AD0-AD15 bus with unspecified information during T1. However, the bus will go into high impedance during T2 and remain in that state for the remainder of the cycle. The B/W output is also activated by the CPU with unspecified information.

Memory Refresh:

This status code indicates that AmZ8002 is accessing the memory to refresh. The refresh cycle consists of three clock periods as depicted in Figure 5. The CPU will activate the \overline{AS} output with a LOW pulse to mark the beginning of a machine cycle and ST0-ST3 outputs will reflect the refresh cycle code. The least significant 9 lines of the AD0-AD15 bus contain the refresh address. Because the memory is word organized, the AD0 will always be LOW. The most significant 7 bus lines are not specified. The \overline{DS} output will remain HIGH for the entire cycle while R/W, B/W and N/S outputs will remain at the same level as in the machine cycle prior to refresh. The AD0-AD15 bus will go into high impedance state during T2 period and remain there for

Figure 3. Addressing Modes.

MOS-229

the remainder of the cycle. The AmZ8002 will activate the MREQ output LOW during the refresh cycle. It should be noted that WAIT input is ignored by the CPU for refresh operations.

I/O Transactions:

There are two status line codes used for I/O transaction cycles. The AmZ8002 provides two separate I/O spaces and two types of instructions called Normal I/O and Special I/O. Each I/O space is addressed by a 16-bit address called port address. The timing for both types of I/O transactions is essentially identical. A typical I/O cycle consists of four clock periods T1, T2, TWA and T3 as shown in Figure 6. The TWA is the wait state; insertion of one wait state for an I/O cycle is always automatic. Additional

wait cycles can be inserted by LOW on the WAIT input. The WAIT input is sampled during every TW state. If this input is LOW, one more wait state will be inserted. Insertion of wait states continues until WAIT input is HIGH. T3 state will follow the last wait state to complete the I/O cycle.

During I/O cycles the ST0-ST3 outputs will reflect appropriate code depending on the type of instruction being executed (Normal I/O or Special I/O). AS output will be pulsed LOW to mark the beginning of the cycle. The CPU drives the AD0-AD15 bus with the 16-bit port address specified by the current instruction. The N/S output will be LOW indicating that CPU is operating in the system mode. It should be recalled that the N/S output is derived from the appropriate bit in the FCW register. All I/O instructions are privileged instructions and will be allowed to

Figure 4. Internal Operation Cycle.

MOS-230

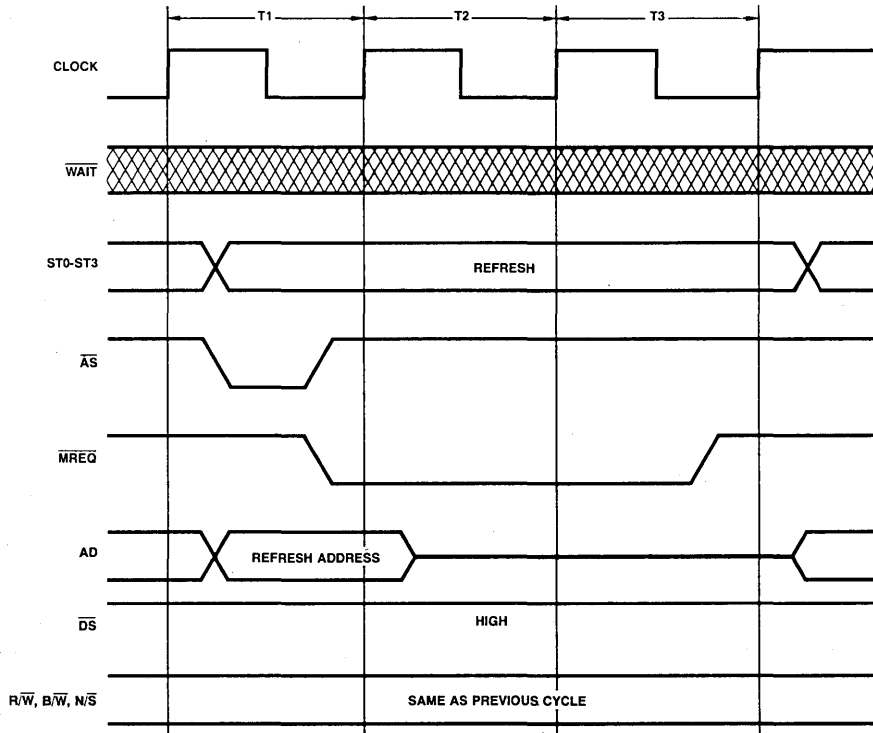

Figure 5. Refresh Cycle.

MOS-231

4

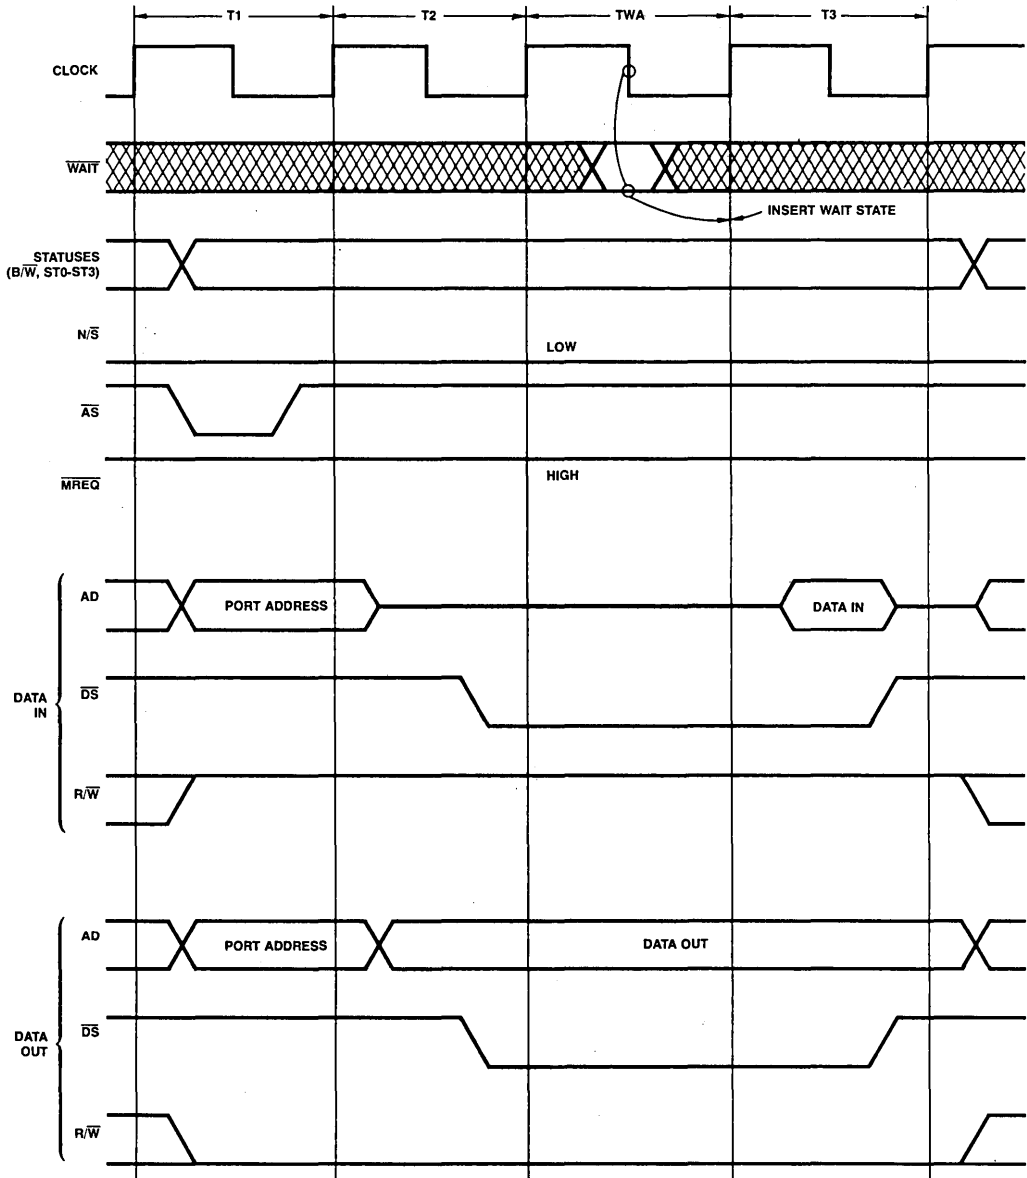

Figure 6. AmZ8002 I/O Cycle.

MOS-232

execute only if the FCW specifies system mode operation. The MREQ output will be HIGH. The AmZ8002 I/O instructions provide both word or byte transactions. The B/W output will be HIGH or LOW depending whether the instruction specifies a byte or word transfer.

Two kinds of I/O transfers should be considered: Data In means reading from the device and Data Out means writing into the device. For In operations, the R/W output will be HIGH. The AD0-AD15 bus will go into high impedance state during T2. During byte input instructions, the CPU reads either the even or odd half of the Data Bus, dependent upon the port address. If the port address is even, the most significant half of the Data Bus is read. If the port address is odd, the least significant half of

the Data Bus is read. During word input instructions, the CPU reads all 16 bits of the Data Bus. The AmZ8002 will drive the DS output LOW to signal to the device that data can be gated on to the bus. The CPU will accept the data during T3 and DS output will go HIGH signalling the end of an I/O transaction.

For Data Out, the R/W output will be LOW. The AmZ8002 will provide data on the AD0-AD15 bus and activates the DS output LOW during T2. During byte output instructions, the CPU duplicates the byte data onto both the high and low halves of the Data Bus and external logic, using A0, enables the appropriate byte port. During word output instructions the CPU outputs data onto all 16 bits of the Data Bus. The DS output goes HIGH during T3 and the cycle is complete.

Memory Transactions:

There are four status line codes that indicate a memory transaction:

- Memory transaction to read or write an operand
- Memory transaction to read from or write into the stack
- Memory transaction to fetch the first word of an instruction (sometimes called IF1)
- Memory transaction to fetch the subsequent word of an instruction (sometimes called IFN).

It can be appreciated that all the above transactions essentially fall into two categories: memory read and memory write. In the case of IF1 and IFN cycles, the memory will be read at the address supplied by the program counter. All AmZ8002 instructions are multiples of 16-bit words. Words are always addressed by an even address. Thus IF1 and IFN cycles involve performing a memory read for words. On the other hand, a memory transaction for operand and stack operation could be a read or write. Moreover, an operand could be a word or a byte. For stack operation involving the implied stack pointer the address will be supplied by the R15 (or R15'). For operand transactions, the

memory address will come from several sources depending on the instruction and the addressing mode. Memory transaction cycle timing is shown in Figure 7. It typically consists of three clock periods T1, T2 and T3. Wait states (TW) can be inserted between T2 and T3 by activating the $\overline{\text{WAIT}}$ input LOW. The $\overline{\text{WAIT}}$ input will be sampled during T2 and during every subsequent TW. The ST0-ST3 outputs will reflect the appropriate code for the current cycle early in T1 and the $\overline{\text{AS}}$ output will be pulsed LOW to mark the beginning of the cycle. The $\overline{\text{N/S}}$ output will indicate whether the normal or system address space will be used for the current cycle. As shown in the figure the $\overline{\text{MREQ}}$ output will go LOW during T1 to indicate a memory operation.

Consider a read operation first. The $\overline{\text{R/W}}$ output will be HIGH. The AmZ8002 will drive the AD0-AD15 with the appropriate address early in T1. During T2, the bus will go into high impedance state and $\overline{\text{DS}}$ output will be activated LOW by the CPU. The data can be gated on to the bus when $\overline{\text{DS}}$ is LOW. During T1 the $\overline{\text{B/W}}$ will also be activated to indicate byte or word will be transacted. The AmZ8002 memory is word organized and words are addressed by even addresses. However, when addressing bytes, the memory address may be odd or even; an even address for

Figure 7. Memory Transactions.

most significant byte of a word and the next odd address for the least significant byte of that word. When reading a byte from the memory, the least significant address bit can be ignored and the whole word containing the desired byte is gated on to the bus. The CPU will pick the appropriate byte automatically. The AmZ8002 will drive the \overline{DS} output HIGH indicating data acceptance.

Consider the write operation next. The $\overline{R/W}$ output will be LOW. The AmZ8002 removes the address and gates out the data to be written on the bus and activates the \overline{DS} output LOW during T2. If the data to be written is a byte then the same byte will be on both halves of the bus. The \overline{DS} output will go HIGH during T3 signifying completion of the cycle.

Interrupt Acknowledge:

There are three status line codes devoted to interrupt acknowledgement. These correspond to non-maskable, vectored and non-vectored interrupts. The Interrupt Acknowledge cycle is illustrated in Figure 8. The \overline{NMI} input of the AmZ8002 is edge detected i.e., a HIGH to LOW input level change is stored in an internal latch. Similar internal storage is not provided for the \overline{VI} and \overline{NVI} inputs. For \overline{VI} and \overline{NVI} inputs to cause an interruption, the corresponding interrupt enable bits in the FCW must be 1. For the following discussion, both the \overline{VIE} and \overline{NVIE} bits in the FCW are assumed to be 1.

As shown in the figure, the \overline{VI} input, \overline{NVI} input and the internal \overline{NMI} latch output are sampled during T3 of the last machine cycle of an instruction.

A LOW on these signals triggers the corresponding interrupt acknowledge sequence described below. The AmZ8002 executes a dummy IF1 cycle prior to entering the actual acknowledge cycle (see memory transactions for IF1 cycle description). During this dummy IF1 cycle, the program counter is not updated; instead the implied system stack pointer ($R15'$) will be decremented. Following the dummy IF1 cycle is the actual interrupt acknowledge cycle.

The interrupt acknowledge cycle typically consists of 10 clock periods; T1 through T5 and five automatic TW (wait) states. As usual, the \overline{AS} output will be pulsed LOW during T1 to mark the beginning of a cycle. The ST0-ST3 outputs will reflect the appropriate interrupt acknowledge code, the \overline{MREQ} output will be HIGH, the $\overline{N/S}$ output remains the same as in the preceding cycle, the $\overline{R/W}$ output will be HIGH and the $\overline{B/W}$ output will be LOW. The AmZ8002 will drive the AD0-AD15 bus with unspecified information during T1 and the bus will go into the high impedance state during T2. Three TWA states will automatically follow T2. The WAIT input will be sampled during the third TWA state.

If LOW, an extra TW state will be inserted and the \overline{WAIT} will be sampled again during TW. Such insertion of TW states continues until the \overline{WAIT} input is HIGH. After the last TW state, the \overline{DS} output will go LOW and two more automatic wait states follow. The interrupting device can gate up to a 16-bit identifier on to the bus when the \overline{DS} output is LOW. The \overline{WAIT} input will be sampled again during the last TWA state. If the \overline{WAIT} input is LOW one TW state will be inserted and the \overline{WAIT} will be sampled during TW. Such TW insertion continues until the \overline{WAIT}

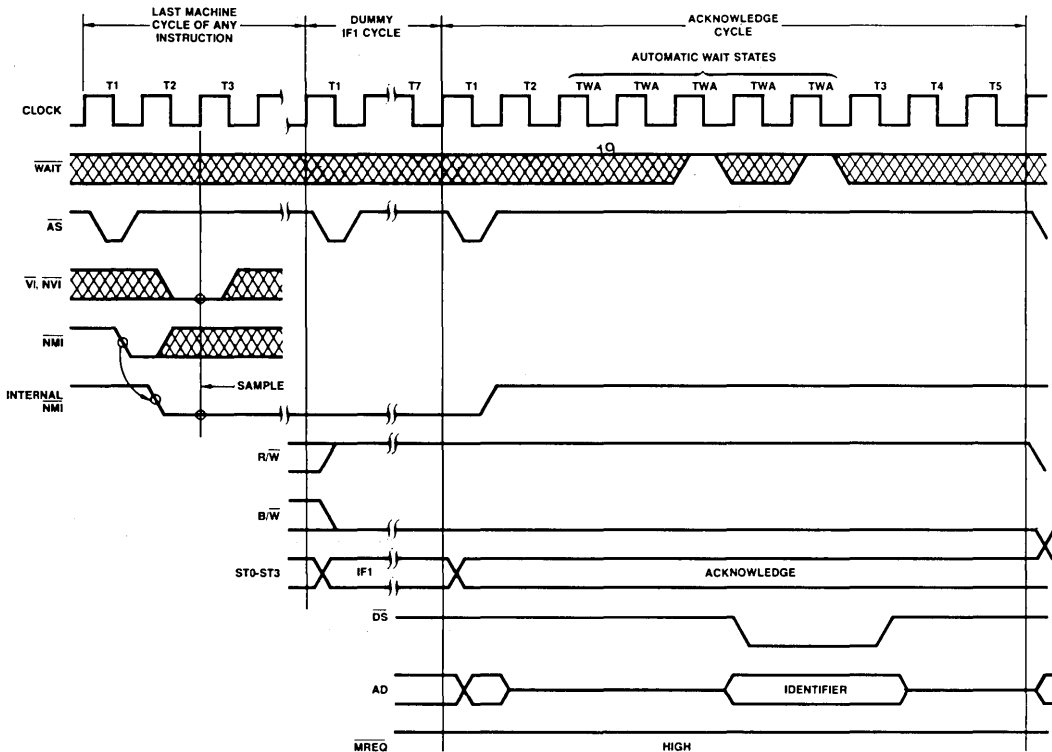

Figure 8. Interrupt Acknowledge Cycle.

input is HIGH. After completing the last TW state T3 will be entered and the \overline{DS} output will go HIGH. The interrupting device should remove the identifier and cease driving the bus. T4 and T5 states will follow T3 to complete the cycle. Following the interrupt acknowledge cycle will be memory transaction cycles to save the status on the stack. Note that the $\overline{N/S}$ output will be automatically LOW during status saving.

The internal \overline{NMI} latch will be reset to the initial state at \overline{AS} going HIGH in the interrupt acknowledge cycle. The \overline{VI} and \overline{NVI} inputs should be kept LOW until this time also.

Status Saving Sequence:

The machine cycles following the interrupt acknowledge cycle push the old status information on the system stack in the following order: the 16-bit program counter; the flag and control word; and finally the interrupt/trap identifier. Subsequent machine cycles fetch the new program status from the new program status area, and then branch to the interrupt/service routine.

BUS REQUEST/BUS ACKNOWLEDGE TIMING:

A LOW on the \overline{BUSRQ} input is an indication to the AmZ8002 that another device (such as DMA) is requesting control of the bus. The \overline{BUSRQ} input is synchronized internally at T1 of any machine cycle. (See below for exception.) The \overline{BUSAK} will go LOW after the last clock period of the machine cycle. The LOW on the \overline{BUSAK} output indicates acknowledgement. When \overline{BUSAK} is LOW the following outputs will go into the high impedance state; AD0-AD15, \overline{AS} , \overline{DS} , \overline{MREQ} , ST0-ST3, B/W, R/W

and $\overline{N/S}$. The \overline{BUSRQ} must be held LOW until all transactions are completed. When \overline{BUSRQ} goes HIGH, it is synchronized internally, the \overline{BUSAK} output will go HIGH and normal CPU operation will resume. Figure 9 illustrates the $\overline{BUSRQ}/\overline{BUSAK}$ timing.

It was mentioned that \overline{BUSRQ} will be honored during any machine cycle with one exception. This exception is during the execution of TSET/TSETB instructions. \overline{BUSRQ} will not be honored once execution of these instructions has started.

SINGLE STEPPING

The \overline{STOP} input of the AmZ8002 facilitates one instruction at a time or single step operation. Figure 10 illustrates \overline{STOP} input timing. The \overline{STOP} input is sampled on the HIGH to LOW transition of the clock input that immediately precedes an IF1 cycle. If the \overline{STOP} is found LOW, AmZ8002 introduces a memory refresh cycle after T3. Moreover, \overline{STOP} input will be sampled again at T3. If \overline{STOP} is LOW one more refresh cycle will follow the previous refresh cycle. The \overline{STOP} will be sampled during T3 of the refresh cycle also. One additional refresh cycle will be added every time \overline{STOP} input is sampled LOW. After completing the last refresh cycle which will occur after \overline{STOP} is HIGH, the CPU will insert two dummy states T4 and T5 to complete the IF1 cycle and resume its normal operations for executing the instruction. See appropriate sections on memory transactions and memory refresh.

It should be noted that refresh cycles will occur in the stop mode even if the refresh facility is disabled in the refresh register.

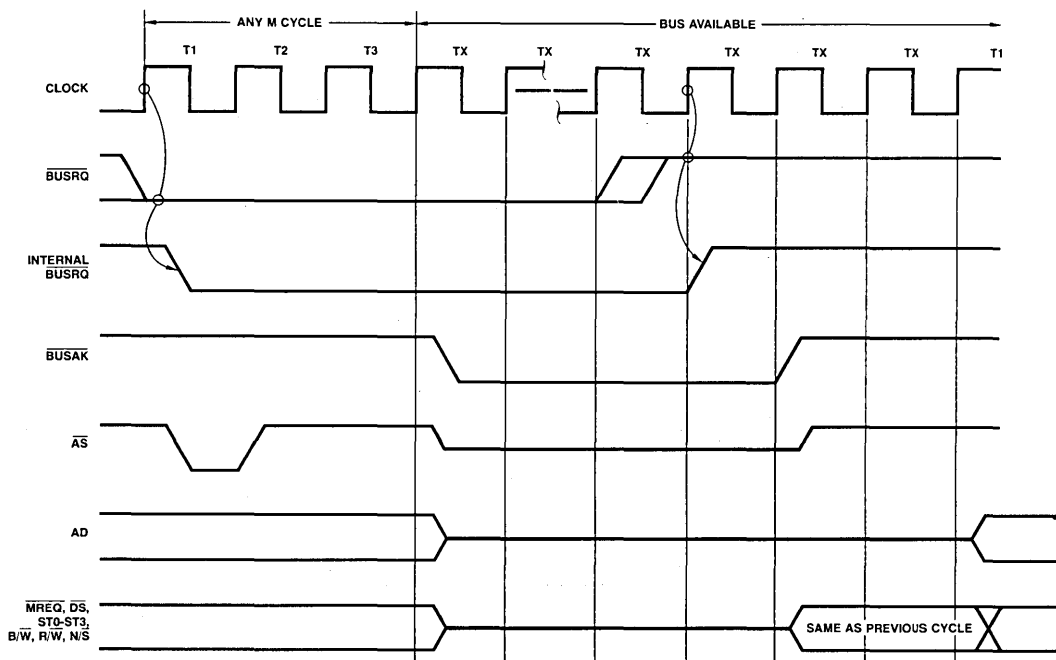

Figure 9. Bus Request/Acknowledge Cycle.

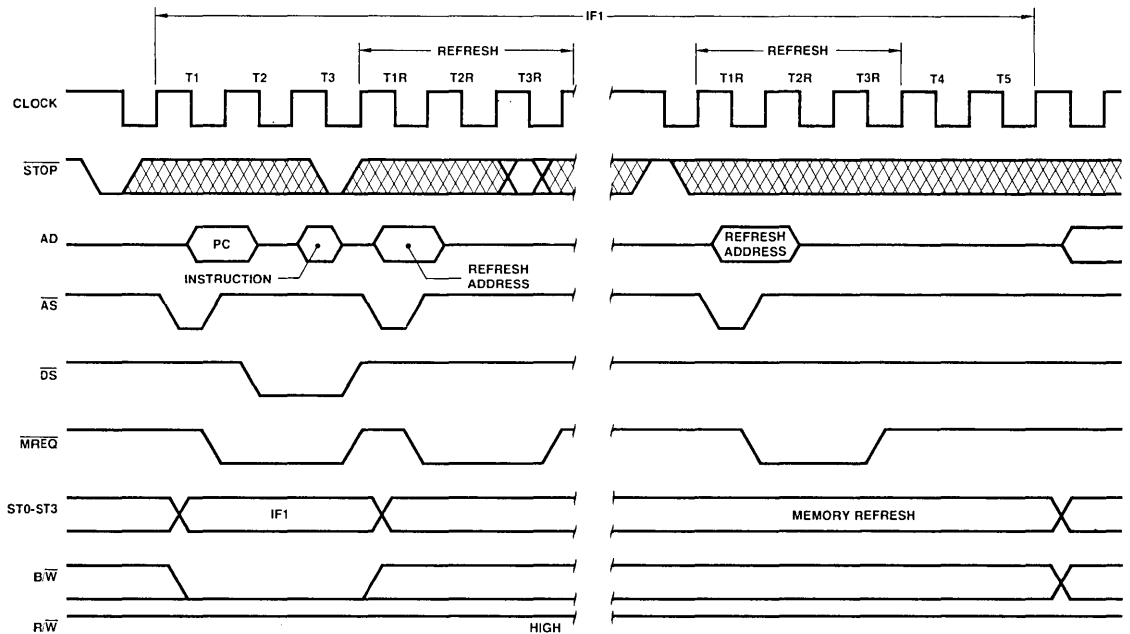

Figure 10. Single Step Timing.

MOS-236

MULTIMICROPROCESSOR FACILITIES

The AmZ8002 is provided with hardware and software facilities to support multiple microprocessor systems. The $\overline{\mu O}$ and $\overline{\mu I}$ signals of the AmZ8002 are used in conjunction with the MBIT, MREQ, MRES and MSET instructions for this purpose. The $\overline{\mu O}$ output can be activated LOW by using an appropriate instruction to signal a request from the AmZ8002 for a resource. The $\overline{\mu I}$ input is tested by the AmZ8002 before activating the $\overline{\mu O}$ output. LOW at the $\overline{\mu I}$ input at this time indicates that the resource is busy. The AmZ8002 can examine the $\overline{\mu I}$ input after activating the $\overline{\mu O}$ output LOW. The $\overline{\mu I}$ will be tested again to see if the requested resource became available. For detailed information on the Multimicroprocessor facilities the AmZ8001/AmZ8002 Processor Interface Manual (Publication No. AM-PUB089) should be consulted.

INITIALIZATION

A LOW on the $\overline{\text{Reset}}$ input starts the CPU initialization. The initialization sequence is shown in Figure 11. Within five clock periods after the HIGH to LOW level change of the $\overline{\text{Reset}}$ input the following will occur:

- a) AD0-AD15 bus will be in the HIGH impedance state
- b) $\overline{\text{AS}}$, $\overline{\text{DS}}$, $\overline{\text{MREQ}}$, $\overline{\text{BUSAK}}$ and $\overline{\mu O}$ outputs will be HIGH
- c) ST0-ST3 outputs will be LOW
- d) Refresh will be disabled
- e) $\overline{\text{R/W}}$, $\overline{\text{B/W}}$ and $\overline{\text{N/S}}$ outputs are not affected. For a power on reset the state of these outputs is not specified.

After the $\overline{\text{Reset}}$ input returns HIGH and remains HIGH for three clock periods, two 16-bit memory read operations will be performed as follows. Note that the $\overline{\text{N/S}}$ output will be LOW and ST0-ST3 outputs will reflect IFN code.

- a) The contents of the memory location 0002 will be read. This information will be loaded into the FCW of the AmZ8002.
- b) The contents of the memory location 0004 will be read. This information will be loaded into the AmZ8002 program counter.

This completes initialization sequence and an IF1 cycle will follow to fetch the first instruction to begin program execution. See the section on memory transactions for timing.

AmZ8002

MAXIMUM RATINGS above which useful life may be impaired

Voltages on all inputs and outputs with respect to GND	-0.3 to +7.0V
Ambient Temperature under bias	0 to 70°C
Storage Temperature	-65 to +150°C

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulations of static charge. It is suggested, nevertheless, that conventional precautions be observed during storage, handling and use in order to avoid exposure to excessive voltages.

V _{OL}	Output Low Voltage	I _{OL} = +2.0mA		0.4	Volts
I _{IL}	Input Leakage	0.4 ≤ V _{IN} ≤ +2.4V		±10	μA
I _{OL}	Output Leakage	0.4 ≤ V _{OUT} ≤ +2.4V		±10	μA
I _{CC}	V _{CC} Supply Current			300	mA

Standard Test Conditions

The characteristics below apply for the following standard test conditions, unless otherwise noted. All voltages are referenced to GND. Positive current flows into the referenced pin. Standard conditions are as follows:

+4.75V ≤ V_{CC} ≤ +5.25V
 GND = 0V
 0°C ≤ T_A ≤ +70°C

MOS-238

All AC parameters assume a load capacitance of 100pF max. Timing references between two output signals assume a load difference of 50pF max.

AmZ8010

Memory Management Unit

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- Logical to Physical address translation
- Dynamic segment relocation
- 64 segments per MMU
- Segment sizes individually assignable from 256 to 64K bytes
- Size limit protection
- Segment protection attributes for system security
 - System only
 - Execute only
 - Read only
 - CPU only
 - Segment invalid
- Segment history aids paging
 - Segment referenced
 - Segment changed

GENERAL DESCRIPTION

The AmZ8010 Memory Management Unit (MMU) is a high-performance, LSI product which adds sophisticated address translation and memory protection capabilities to AmZ8001 CPU systems. Addresses output by the CPU consist of a 7-bit segment number and a 16-bit offset. The MMU uses the segment number to index an address translation table. The offset is added to the segment base to form the physical address. A separate table allows the user to individually program each segment size from 256 to 64K bytes.

The MMU also contains a table of access attributes which are individually programmable for each segment. Attributes provided are Read Only, System Mode Only, Invalid Segment, Execute Only, and CPU Only (Exclude DMA). A trap is issued to the CPU and writes to memory are suppressed if an access is attempted which is prohibited by the attributes or which falls outside of the programmed segment size.

MOS-294

AmZ8016

DMA Transfer Controller

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- Two independent high-speed DMA channels
- Memory/Peripheral transfers up to 2M bytes/sec
- Memory/Memory transfers up to 1.3M bytes/sec
- Fully compatible with AmZ8000 systems
- Full 8M byte logical addressing range
- Supports both logical and physical addressing
- Control parameters self-loaded from memory
- Successive transfer operations automatically chained without CPU intervention
- Base registers for efficient repetitive operations
- Programmable data matching with masking
- Vectored interrupts facilitate control coordination with CPU
- 48-pin DIP package
- +5V power supply

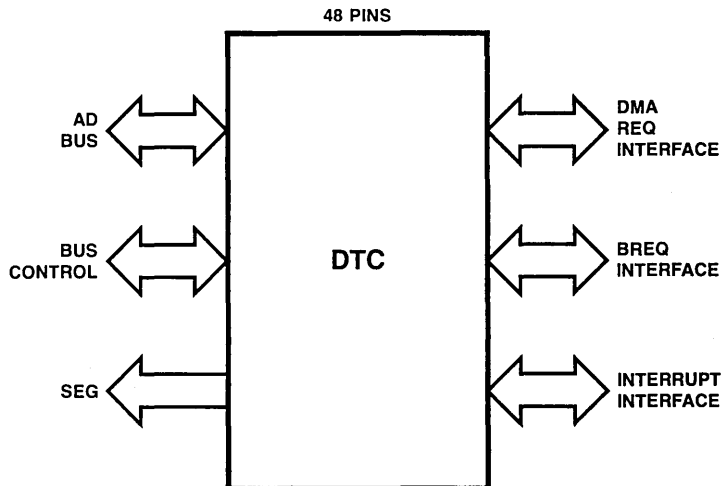

GENERAL DESCRIPTION

The AmZ8016 Direct Memory Access Transfer Controller (DTC) is a high-performance, LSI peripheral support circuit. With full AmZ8000 family bus compatibility, the DTC has been designed for ease of use in a variety of environments.

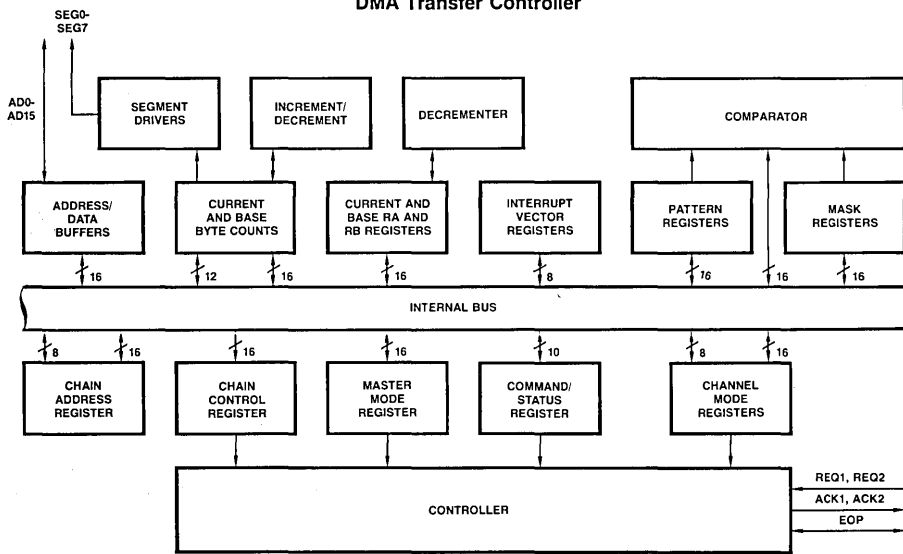

The AmZ8016 supports high-speed transfers between any mix of word/byte and memory/IO sources. To support variable length data blocks, the DTC permits search and transfer-and-search operations. Either 8-bit or 16-bit patterns may be used with masking, to permit searching for control codes or other specialized bit patterns. Communications between the DTC and the CPU is enhanced by an interrupt interface.

Included on the DTC are base registers permitting automatic reloading of the source, destination and byte count registers without bus overhead. Moreover, each channel contains circuitry capable of reloading any of the channel's registers from a control block in memory. Control blocks can be chained together. Since the DTC may be programmed to generate either physical or logical addresses it may be used either with or without an AmZ8010 Memory Management Unit and may be physically positioned with the peripheral (distributed DMA) or with the CPU (central DMA).

MOS-297

AmZ8030

Serial Communications Controller

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- Two independent serial full-duplex channels
- Buffered receiver and transmitter data registers
- All popular data formats
 - Asynchronous
 - Synchronous Byte Oriented protocols
 - Synchronous Bit Oriented protocols
- Data rates up to 880K bits/sec
- CRC-16 or CCITT block frame check
- Internal baud rate generation
- Separate modem controls for both channels
- Interrupt interface with programmable interrupt vectors
- 40-pin DIP package
- +5V power supply

GENERAL DESCRIPTION

The AmZ8030 is a high-performance dual-channel multifunction serial communication controller (SCC). It is capable of handling serial-to-parallel and parallel-to-serial conversions for asynchronous modes, synchronous byte-oriented protocols such as IBM bisync, and synchronous bit-oriented protocols such as HDLC and SDLC. It generates and checks CRC codes in any synchronous mode.

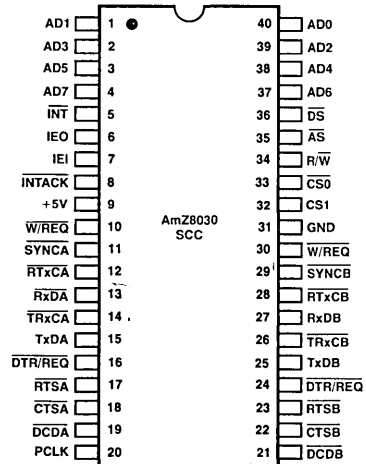

It features two independent sets of four modem control signals with quadruply buffered receiver data and doubly buffered transmitter data for more tolerant host processor or DMA data transfers. Each channel includes baud rate generation.

Its flexible daisy chain priority interrupt structure allows it to output an interrupt vector pointing to the correct routine by providing prioritized status information for the transmitter, receiver and External/Status interrupts. It can also be used in a polled environment or can output interrupt without vector.

AmZ8036

Counter/Timer and Parallel I/O Unit

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- Two general purpose 8-bit I/O ports
- Special purpose 4-bit control port
- Three independent 16-bit counter/timers
- Data Pattern matching with masking
- Interrupt control and interface
- Bit interface option
- One's catching input option
- Open drain output option
- Interlocked, pulsed, strobed or 3-wire handshaking
- 40-pin DIP package
- +5V power supply

GENERAL DESCRIPTION

The AmZ8036 counter/timer and parallel I/O is a general purpose peripheral device. It can perform as an interrupt controller as well as a flexible parallel data interface with various handshaking modes. Two double-buffered general purpose 8-bit ports can be used independently or linked to form a 16-bit port. The port bits can also operate individually with each bit direction individually programmable. A 4-bit port can be used as I/O or to provide handshake controls. Data pattern matching with individually maskable bits is available for each 8-bit port.

Three independent 16-bit counters can operate in single or continuous cycles. Two may be linked together internally. The counters can count internal clocks or can count external events.

BLOCK DIAGRAM

MOS-303

AmZ8038

FIFO Input/Output Interface Unit

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- General purpose FIFO buffered 8-bit I/O port
- 128 x 8 internal bidirectional FIFO
- Expandable in width and depth
- Buffers CPU to CPU and CPU to peripheral
- Simultaneous asynchronous read and write operations
- Interrupt Daisy Chain Interface
- Eight prioritized vectored interrupt sources
- General purpose or CPU-Bus interface
- Flyby DMA interface
- Pattern matching with mask
- IEEE-488 or Interlocked handshake post
- 40-pin DIP package
- +5V power supply

GENERAL DESCRIPTION

The AmZ8038 FIFO I/O (FIO) is a general-purpose 8-bit I/O port with a 128 x 8 bidirectional FIFO buffer memory between the port and the CPU bus. It functions as a buffered "elastic" general purpose interface. It has an 8-bit Master side which controls direction of data transfer, and 8-bit slave side which follows the data direction. It is capable of simultaneous, asynchronous, independent read and write operations.

The AmZ8038 has several control lines that may be used to interface to a DMA device or to synchronize the servicing processor. Two handshake lines allow direct interfacing to other peripheral devices. Buffer status (FULL and EMPTY) is also available as separate pins. Byte pattern matching with individual bit masking is available to generate an interrupt or to disable data loading. A daisy chain interrupt structure with eight prioritized Vectors is available for status information to the host processor.

Many types of handshaking interfaces are available including Interlocked and IEEE-488.

BLOCK DIAGRAM

MOS-306

AmZ8052

CRT Controller

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- 16-bit Address/Data port for host processor
- Multiple character attributes on a per-character basis
- Redefinable row attributes
- Linked list buffer addressing
- External source vertical frame rate sync input
- Flexible vertical and horizontal sync and blank control
- Programmable vertical and horizontal split-screen capability
- 5-bit Character Generator row addressing
- Super/subscript capability
- Multiple cursors
- Variable scans per row
- 48-pin package
- Various blink rates and duty cycles for characters and cursor
- Variable character clock frequency
- +5V power supply

GENERAL DESCRIPTION

The AmZ8052 CRTC is a new generation raster scan alphanumeric display controller. It features host processor access to the display memory without contention; linked list addressing of character data; double character per cell display with variable vertical position; vertical retrace synchronization to an external source; and a variable character clock frequency input for character justification or character font mix. Scan lines per character are variable on row-by-row basis. Blinking rates are individually selectable for cursors and characters.

Row attributes define the address of the character data, scan line count of the current row, vertical shift options per character row and vertical split screen location. Character attributes are stored on a character-by-character basis.

MOS-308

AmZ8060

FIFO Buffer Unit and FIO Expander

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- General purpose 8-bit FIFO
- 128 x 8 bidirectional FIFO
- Expandable in width and depth
- Extends depth capability of AmZ8038 FIO
- Asynchronous
- +5V power supply

GENERAL DESCRIPTION

The AmZ8030 FIFO is a 128 x 8 bidirectional buffer. It is designed to operate as a stand-alone FIFO or to be used to expand the AmZ8033 buffer depth. The FIFO buffers can be cascaded without limit by daisy-chaining the RFD/DAV and ACKIN signals. The structure of the AmZ8038 FIFOs are similar to the Am2812. The FIFO is capable of simultaneous, asynchronous, independent read and write operations.

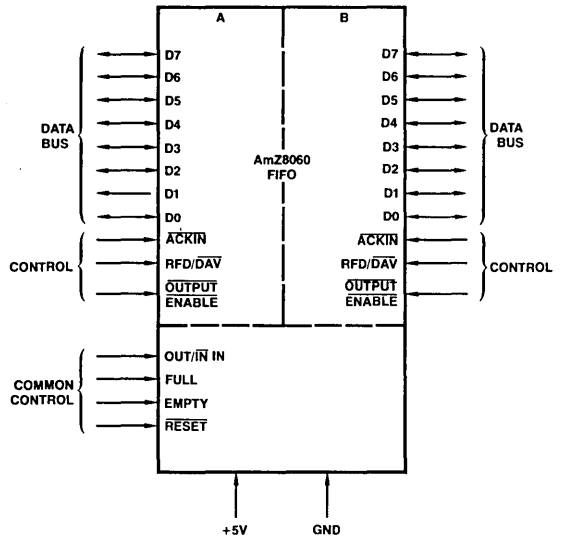

The AmZ8038 has control lines that may be used to interface to other devices or to synchronize the servicing processor. Two handshake lines allow direct interfacing to other peripheral devices. Buffer status (FULL and EMPTY) is also available as separate pins.

EXTENDING THE FIOs WITH FIFOs

MOS-311

AmZ8065

Burst Error Processor

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

- Burst error detection and correction
- Four selectable industry-standard polynomials including 56 and 48-bit IBM versions
- Serial data rates up to 20M bits/sec
- 12-bit error pattern output
- High-speed correction facilities based on Chinese Remainder theorem
- Single burst error correction
- Selectable error check modes in write mode
- 8-bit data port
- 40-pin DIP package
- -5V power supply

GENERAL DESCRIPTION

The AmZ8065 Burst Error Processor (BEP) is a peripheral interface circuit for serial or parallel data error detection and correction. It is used in applications such as high performance disk systems. Four different generator polynomials are internally encoded to satisfy a broad range of applications.

Data is entered in 8-bit (byte) parallel format and check bits are provided in the same parallel format.

Write data is entered on the fly into the AmZ8065 while blocks are written to the associated disk and check bits are extracted following the last data byte. A Read Normal mode performs extraction of the error pattern and location while a Read High Speed mode allows direct division of data by the factors of the generator polynomial. A Divide mode generates output check bits and validates data. The Compute mode initiates a data correction process by locating and outputting the error pattern for correction.

AmZ8068

Data Ciphering Processor

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

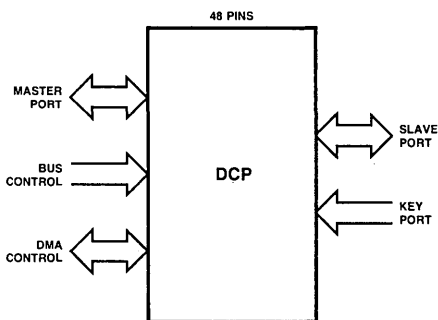

- Standard encryption and decryption algorithms
- Throughput rates greater than 1 megabyte per second
- Supports three standard ciphering options
 - Electronic Code Book
 - Cipher Feedback
 - Chain Block
- Master, Encrypt and Decrypt key registers
- Key parity check
- Separate key port
- Session keys and Initializing Vectors may be entered encrypted or clear
- Master data port for bidirectional bus operation
- Slave data port for pipelined operation
- 40-pin DIP package
- +5V power supply

GENERAL DESCRIPTION

The AmZ8068 Data Ciphering Processor is an N-channel silicon gate LSI product containing the circuitry necessary to encrypt and decrypt data using the National Bureau of Standards encryption algorithm. It is designed to be used in a variety of environments including dedicated controllers, communication concentrators, terminals and peripheral task processors in general processor systems. The DCP provides a high throughput rate using Cipher Feedback, Electronic Code Book or Chain Block Cipher operating modes. Separate ports are provided for key input, clear data and enciphered data to enhance security.

The system communicates with the Am8068 using commands entered in the master port and through auxiliary control lines. Once set up, data can flow through the DCP at high speeds because input, output and ciphering activities are all performed concurrently. External DMA control can easily be used to enhance throughput in some system configurations. This device is designed to interface directly to the AmZ8000 CPU bus and, with a minimum of external logic, to the 2900, 8080, 8085 and 8048 families of processors.

MOS-316

AmZ8073

System Timing Controller

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

- Five independent 16-bit counters
- High speed counting rates
- Up/down and binary/BCD counting
- Internal oscillator frequency source
- Tapped frequency scaler
- Programmable frequency output
- 8-bit or 16-bit bus interface
- Time-of-day option
- Alarm comparators on counters 1 and 2
- Complex duty cycle outputs
- One-shot or continuous outputs
- Programmable count/gate source selection
- Programmable input and output polarities
- Programmable gating functions
- Retriggering capability
- +5 volt power supply
- Standard 40-pin package
- 100% MIL-STD-883 reliability assurance testing

GENERAL DESCRIPTION

The AmZ8073 System Timing Controller is an LSI circuit designed to service many types of counting, sequencing and timing applications. It provides the capability for programmable frequency synthesis, high resolution programmable duty cycle waveforms, retriggerable digital one-shots, time-of-day clocking, coincidence alarms, complex pulse generation, high resolution baud rate generation, frequency shift keying, stop-watching timing, event count accumulation, waveform analysis and many more. A variety of programmable operating modes and control features allow the AmZ8073 to be personalized for particular applications as well as dynamically reconfigured under program control.

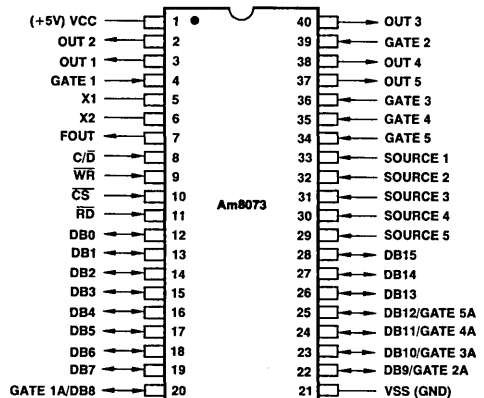

The STC includes five general-purpose 16-bit counters. A variety of internal frequency sources and external pins may be selected as inputs for individual counters with software selectable active-high or active-low input polarity. Both hardware and software gating of each counter is available. Three-state outputs for each counter provide pulses or levels and can be active-high or active-low. The counters can be programmed to count up or down in either binary or BCD. The host processor may read an accumulated count at any time without disturbing the counting process. Any of the counters may be internally concatenated to form any effective counter length up to 80 bits.

AmZ8103 • AmZ8104

Octal Three-State Bidirectional Bus Transceivers

DISTINCTIVE CHARACTERISTICS

- 8-bit bidirectional data flow reduces system package count
- 3-state inputs/outputs for interfacing with bus-oriented systems
- PNP inputs reduce input loading
- VCC – 1.15V V_{OH} interfaces with TTL, MOS and CMOS
- 48mA, 300pF bus drive capability
- AmZ8103 inverting transceivers
- AmZ8104 non-inverting transceivers
- Transmit/Receive and Chip Disable simplify control logic
- 20-pin ceramic and molded DIP package
- Low power – 8mA per bidirectional bit
- Advanced Schottky processing
- Bus port stays in hi-impedance state during power up/down
- 100% product assurance screening to MIL-STD-883 requirements

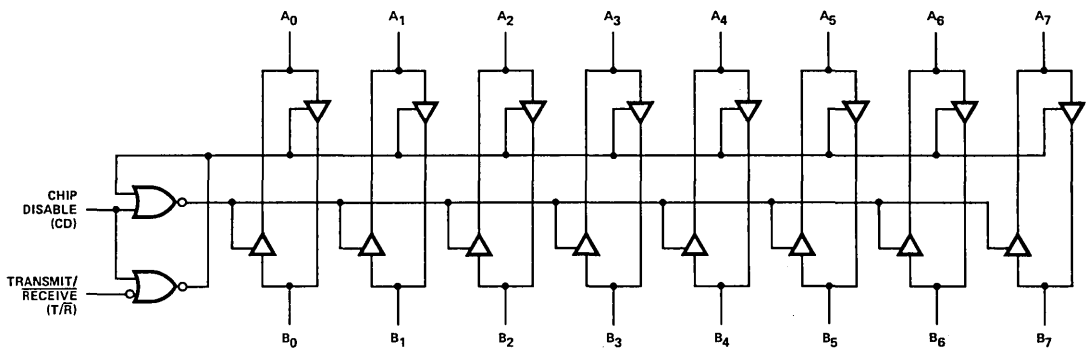

FUNCTIONAL DESCRIPTION

The AmZ8103 and AmZ8104 are 8-bit 3-state Schottky transceivers. They provide bidirectional drive for bus-oriented microprocessor and digital communications systems. Straight through bidirectional transceivers are featured, with 24mA drive capability on the A ports and 48mA bus drive capability on the B ports. PNP inputs are incorporated to reduce input loading.

One input, Transmit/Receive determines the direction of logic signals through the bidirectional transceiver. The Chip Disable input disables both A and B ports by placing them in a 3-state condition. Chip Disable is functionally the same as an active LOW chip select.

The output high voltage (V_{OH}) is specified at VCC – 1.15V minimum to allow interfacing with MOS, CMOS, TTL, ROM, RAM, or microprocessors.

Notes: 1. All typical values given are for VCC = 5.0V and TA = 25°C.

2. Only one output at a time should be shorted.

DEFINITION OF FUNCTIONAL TERMS

A0-A7 A port inputs/outputs are receiver output drivers when T/R is LOW and are transmit inputs when T/R is HIGH.

B0-B7 B port inputs/outputs are transmit output drivers when T/R is HIGH and receiver inputs when T/R is LOW.

CD Chip Disable forces all output drivers into 3-state when HIGH (same function as active LOW chip select, CS).

T/R Transmit/Receive direction control determines whether A port or B port drivers are in 3-state. With T/R HIGH A port is the input and B port is the output. With T/R LOW A port is the output and B port is the input.

AmZ8107 • AmZ8108

Octal Three-State Bidirectional Bus Transceivers

DISTINCTIVE CHARACTERISTICS

- 8-bit bidirectional data flow reduces system package count
- 3-state inputs/outputs for interfacing with bus-oriented systems
- PNP inputs reduce input loading
- VCC - 1.15V VOH interfaces with TTL, MOS, and CMOS
- 48mA, 300pF bus drive capability
- AmZ8107 has inverting transceivers
- AmZ8108 has non-inverting transceivers
- Separate TRANSMIT and RECEIVE Enables
- 20 pin ceramic and molded DIP package
- Low power - 8mA per bidirectional bit
- Advanced Schottky processing
- Bus port stays in hi-impedance state during power up/down
- 100% product assurance screening to MIL-STD-883 requirements

GENERAL DESCRIPTION

The AmZ8107 and AmZ8108 are 8-bit, 3-state Schottky transceivers. They provide bidirectional drive for bus-oriented microprocessor and digital communications systems. Straight through bidirectional transceivers are featured, with 24mA drive capability on the A ports and 48mA bus drive capability on the B ports. PNP inputs are incorporated to reduce input loading.

Separate TRANSMIT and RECEIVE Enables are provided for microprocessor system with separated read and write control bus lines.

The output high voltage (VOH) is specified at VCC - 1.15V minimum to allow interfacing with MOS, CMOS, TTL, ROM, RAM, or microprocessors.

AmZ8120

Octal D-Type Flip-Flop with Clear, Clock Enable and 3-State Control

DISTINCTIVE CHARACTERISTICS

- Buffered common clock enable input
- Buffered common asynchronous clear input
- Three-state outputs
- 8-bit, high-speed parallel register with positive edge-triggered, D-type flip-flops
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8120 is an 8-bit register built using advanced Low-Power Schottky technology. The register consists of eight D-type flip-flops with a buffered common clock, a buffered common clock enable, a buffered asynchronous clear input, and three-state outputs.

When the clear input is LOW, the internal flip-flops of the register are reset to logic 0 (LOW), independent of all other inputs. When the clear input is HIGH, the register operates in the normal fashion.

When the three-state output enable (\overline{OE}) input is LOW, the Y outputs are enabled and appear as normal TTL outputs. When the output enable (\overline{OE}) input is HIGH, the Y outputs are in the high impedance (three-state) condition. This does not affect the internal state of the flip-flop Q output.

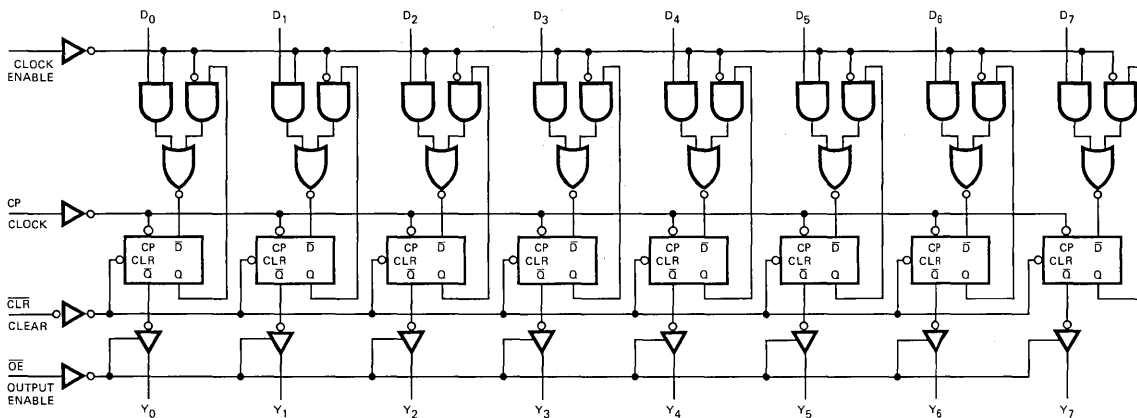

The clock enable input (\overline{E}) is used to selectively load data into the register. When the \overline{E} input is HIGH, the register will retain its current data. When the \overline{E} is LOW, new data is entered into the register on the LOW-to-HIGH transition of the clock input.

This device is packaged in a slim 24-pin package (0.3 inch row spacing).

DEFINITION OF FUNCTIONAL TERMS

D_i The D flip-flop data inputs.

$\overline{\text{CLR}}$ When the clear input is LOW, the Q_i outputs are LOW, regardless of the other inputs. When the clear input is HIGH, data can be entered into the register.

CP Clock Pulse for the Register; enters data into the register on the LOW-to-HIGH transition.

Y_i The register three-state outputs.

$\overline{\text{E}}$ Clock Enable, When the clock enable is LOW, data on the D_i input is transferred to the Q_i output on the LOW-to-HIGH clock transition. When the clock enable is HIGH, the Q_i outputs do not change state, regardless of the data or clock input transitions.

$\overline{\text{OE}}$ Output Control. When the $\overline{\text{OE}}$ input is HIGH, the Y_i outputs are in the high impedance state. When the $\overline{\text{OE}}$ input is LOW, the TRUE register data is present at the Y_i outputs.

FUNCTION TABLE

Function	Inputs					Internal	Outputs

AmZ8121

Eight-Bit Equal-To Comparator

DISTINCTIVE CHARACTERISTICS

- 8-bit byte oriented equal-to comparator
- Cascadable using \overline{E}_{IN}
- High-speed, Low-Power Schottky technology
- $t_{pd} A \odot B$ to \overline{E}_{OUT} in 9ns
- Standard 20-pin package
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8121 is an 8-bit "equal to" comparator capable to comparing two 8-bit words for "equal to" with provision for expansion or external enabling. The matching of the two 8-bit inputs plus a logic LOW on the \overline{E}_{IN} produces an active LOW on the output \overline{E}_{OUT} .

The logic expression for the device can be expressed as:

$$\overline{E}_{OUT} = (A_0 \odot B_0) (A_1 \odot B_1) (A_2 \odot B_2) (A_3 \odot B_3) (A_4 \odot B_4) (A_5 \odot B_5) (A_7 \odot B_7) \overline{E}_{IN}$$
 It is obvious that the expression is valid where $A_0 - A_7$ and $B_0 - B_7$ are expressed as either assertions or negations. This is also true for pair of terms i.e. A_0 can be compared with B_0 at the same time \overline{A}_1 is compared with \overline{B}_1 . It is only essential that the polarity of the paired terms be maintained.

AmZ8000 Clock Generator and Controller

Advanced Information

DISTINCTIVE CHARACTERISTICS

- High-drive high-level clock output**
 Special output provides clock signal matched to requirements of AmZ8000 CPU, MMU and DMA devices.
- Four TTL-level clocks**
 Generates synchronized TTL compatible clocks at 16MHz, 2MHz and 1MHz to drive memory circuits and LSI peripheral devices. An additional TTL clock is synchronized with the high-level clock for registers, latches and other peripherals.
- Synchronized WAIT state and time-out controls**
 On-chip logic generates WAIT signal under control of Halt, Single-step and Ready signals. Automatic time-out of peripheral wait requests.

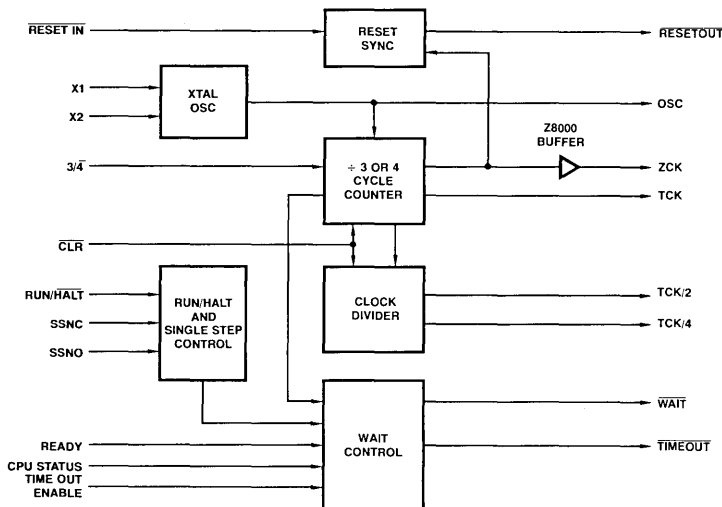

FUNCTIONAL DESCRIPTION

The AmZ8127 Clock Generator and Controller provides the clock oscillator, frequency dividers and clock drivers for the complete array of AmZ8000 CPUs, peripherals and memory system configurations. In addition to the special 4MHz output driver for the AmZ8001 and AmZ8002 CPUs, a standard buffered TTL 16MHz oscillator output is provided for dynamic memory timing and control. The AmZ8127 forms an integral part of the dynamic memory support chip set including the AmZ8163 EDC and Refresh Controller, AmZ8164 Dynamic Memory Controller, AmZ8160 Error Detection and Correction Unit and AmZ8161/AmZ8162 EDC Bus Buffers. The oscillator is designed to operate with a 16MHz crystal or with external 16MHz drive. The AmZ8127 uses an internal divide-by-4 to provide 4MHz clock drive to the AmZ8001/AmZ8002 CPU. Additional dividers generate synchronous buffered 2MHz and 1MHz clock outputs for use by peripheral devices. The clock divider counters are clearable to allow synchronizing the multiple clock outputs.

The controller functions include $\overline{\text{RESET}}$, $\text{RUN}/\overline{\text{HALT}}$, SINGLE-STEP , READY and a READY TIMEOUT counter which limits a peripheral's wait request to 16 clock cycles. The CPU's WAIT input is controlled by $\text{RUN}/\overline{\text{HALT}}$, SINGLE-STEP and READY . A $\overline{\text{HALT}}$ command to the AmZ8127 drives the WAIT output LOW causing the CPU to add wait states (TW to TW). The READY input is used by peripherals to request wait states. The active HIGH input TIMEOUT ENABLE is used to force TIMEOUT and WAIT to HIGH 16 clock cycles after a peripheral has requested a wait but fails to release the request. The CPU status lines ST1, ST2 and ST3 are decoded in the AmZ8127 to disable the TIMEOUT counter during CPU "Internal Operations" and during refresh.

Octal Latches with Three-State Outputs

DISTINCTIVE CHARACTERISTICS

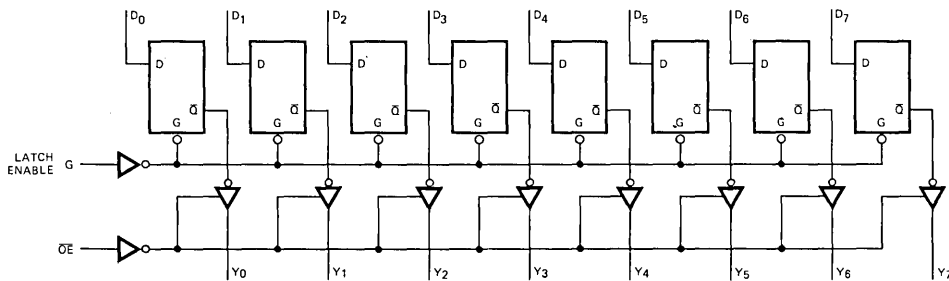

- 18ns max data in to data out
- Non-inverting AmZ8173, inverting AmZ8133
- Three-state outputs interface directly with bus organized systems
- Hysteresis on latch enable input for improved noise margin
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8133 and AmZ8173 are octal latches with three-state outputs for bus organized system applications. The latches appear to be transparent to the data (data changes asynchronously) when latch enable, G, is HIGH. When G is LOW, the data that meets the set-up times is latched. Data appears on the bus when the output enable, OE, is LOW. When OE is HIGH the bus output is in the high-impedance state.

The AmZ8173 has non-inverted data inputs while the AmZ8133 is inverting.

- OE** The output enable control. When OE is LOW, the inverted outputs Y_i are enabled. When OE is HIGH, the outputs Y_i are in the high-impedance (off) state.

AmZ8136

Eight-Bit Decoder With Control Storage

DISTINCTIVE CHARACTERISTICS

- 8-bit decoder/demultiplexer with control storage
- 3-state outputs
- Common clock enable
- Common clear
- Polarity control
- Advanced Low Power Schottky Process
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8136 is an eight-bit decoder with control storage. It provides a conventional 8-bit decoder function with two enable inputs which may also be used for data input. This can be used to implement a demultiplexer function. In addition, the "exclusive-OR" gates provide polarity control of the selected output. The 3-state outputs are enabled by an active LOW input on the output enable, \overline{OE} .

The three control bits representing the output selection and the single bit polarity control are stored in "D" type flip-flops. These flip-flops have Clear, Clock, and Clock Enable functions provided. The \overline{G}_1 and G_2 inputs provide either polarity for input control or data.

DEFINITION OF TERMS

- \overline{CLR}** CLEAR – When the CLEAR input is LOW, the control register outputs (QA, QB, QC, QPOL) are set LOW regardless of any other inputs.
- CP** CLOCK – Enters data into the control register on the LOW-to-HIGH transition.
- \overline{CE}** CLOCK ENABLE – Allows data to enter the control register when \overline{CE} is LOW. When \overline{CE} is HIGH, the Q_i outputs do not change state, regardless of data or clock input transitions.
- A, B, C** Inputs to the control register which are entered on the LOW-to-HIGH clock transition if \overline{CE} is LOW.
- POL** Input to the control register bit used for determining the polarity of the selected output.
- \overline{G}_1** Active LOW part of the expression $G = G_1G_2$ [or $G = (G_1)G_2$] where G is either data input for the selected Y_n or is used as an input enable.
- G₂** Active HIGH part of the expression $G = G_1G_2$.
- Y_n** The three-state outputs. When active ($\overline{OE} = \text{LOW}$), one of eight outputs is selected by the code stored in the control register, with the polarity of all eight determined by the bit stored in the POL flip-flop of the control register. The selected output can further be controlled by G according to the expression $Y_{\text{SELECTED}} = G \oplus Q_{\text{POL}}$.
- \overline{OE}** OUTPUT ENABLE. When \overline{OE} is HIGH the Y_n outputs are in the high impedance state; when \overline{OE} is LOW the Y_n's are in their active state as determined by the other control logic. The \overline{OE} input affects the Y_n output buffers only and has no effect on the control register or any other logic.

AmZ8140 • AmZ8144

Octal Three-State Buffers

DISTINCTIVE CHARACTERISTICS

- Three-state outputs drive bus lines directly
- Hysteresis at inputs improves noise margin
- PNP inputs reduce DC loading on bus lines
- Data-to-output propagation delay times – 16ns MAX
- Enable-to-output – 20ns MAX
- 48mA output current
- 20-pin hermetic and molded DIP packages
- 100% product assurance testing to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

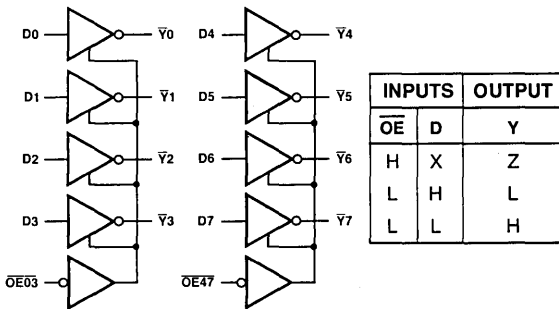

The AmZ8140 and AmZ8144 are octal buffers fabricated using advanced low-power Schottky technology. The 20-pin package provides improved printed circuit board density for use in memory address and clock driver applications.

Three-state outputs are provided to drive bus lines directly. The AmZ8140 and AmZ8144 are specified at 48mA and 24mA output sink current. Four buffers are enabled from one common line and the other four from a second enable line. The AmZ8140 and AmZ8144 enables are of similar polarity for use as a unidirectional buffer in which both halves are enabled simultaneously.

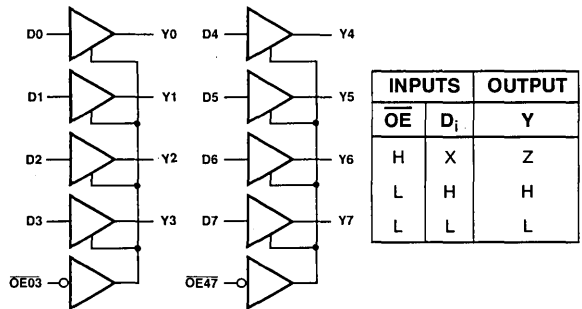

Improved noise rejection and high fan-out are provided by input hysteresis and low current PNP inputs.

APPLICATION

BLI-199

METALLIZATION AND PAD LAYOUTS

AmZ8148

Chip Select Address Decoder With Acknowledge

DISTINCTIVE CHARACTERISTICS

- One-of-Eight Decoder provides eight chip select outputs
- Acknowledge output responds to enables and acknowledge input command
- Open-collector Acknowledge output for wired-OR application
- Inverting and non-inverting enable inputs for upper address decoding
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8148 Address Decoder combines a three-line to eight-line decoder with four qualifying enable inputs (two active HIGH and two active LOW) and the acknowledge output required for "ready" or "wait state" control of all popular MOS microprocessors.

The acknowledge output, ACK, is active LOW and responds to the combination of all enables and an acknowledge active, input command.

The eight chip select outputs are individually active LOW in response to the combination of all enables active and the corresponding 3-bit input code at the S inputs.

The AmZ8148 is intended for chip select decoding in small, medium or large systems where multiple chip selects must be generated and address space must be allocated conservatively.

4

DEFINITION OF FUNCTIONAL TERMS

S_0, S_1, S_2 Three-line to eight-line chip select decoder inputs.

\bar{E}_1, \bar{E}_2 The active LOW enable inputs. A HIGH on either the \bar{E}_1 or \bar{E}_2 input forces all decoded functions to be disabled, and forces \bar{ACK} HIGH.

E_3, E_4 The active HIGH enable inputs. A LOW on either E_3 or E_4 inputs forces all the decoded functions to be inhibited, and forces \bar{ACK} HIGH.

A_0, A_1 The acknowledge inputs, A_0 and A_1 , are active LOW inputs used as conditions for an active LOW output at the acknowledge, \bar{ACK} , output.

\bar{ACK} The acknowledge output, \bar{ACK} , is an active LOW output used to signal the microprocessor that specific devices have been selected. \bar{ACK} goes LOW only when \bar{E}_1 and \bar{E}_2 are LOW, E_3 and E_4 are HIGH and \bar{A}_0 or \bar{A}_1 is LOW.

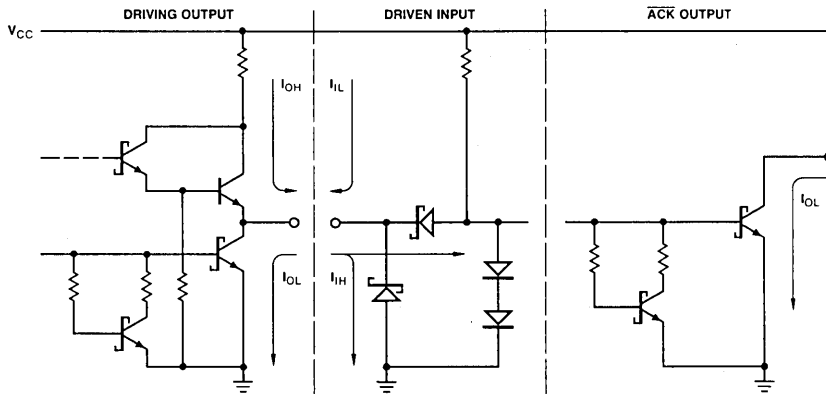

\bar{Y}_i The eight active LOW chip select outputs.

AmZ8160

Cascadable 16-Bit Error Detection and Correction Unit

ADVANCED DATA

DISTINCTIVE CHARACTERISTICS

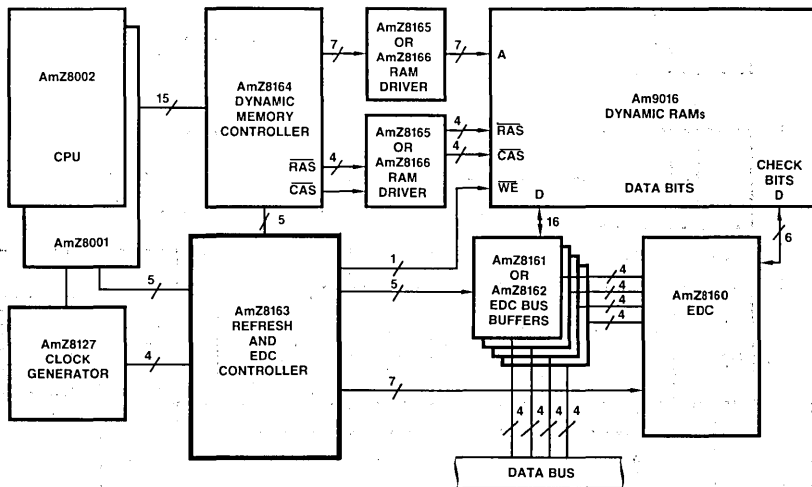

- **Modified Hamming Code**
Detects multiple errors and corrects single bit errors in a parallel data word. Ideal for use in dynamic memory systems.
- **Syndromes provided**
The AmZ8160 makes available the syndrome bits when an error occurs so the location of memory faults can be logged.
- **Microprocessor compatible**
The AmZ8160 is designed to work with AmZ8000 microprocessor systems.
- **Advanced circuit and process technologies**
Newest bipolar LSI techniques provide very high performance.
Data-in to error detection typically 30ns
Data-in to corrected data out typically 50ns
- **Built-in Diagnostics**
Extra logic on the chip provides diagnostic functions to be used during device test and for system diagnostics.

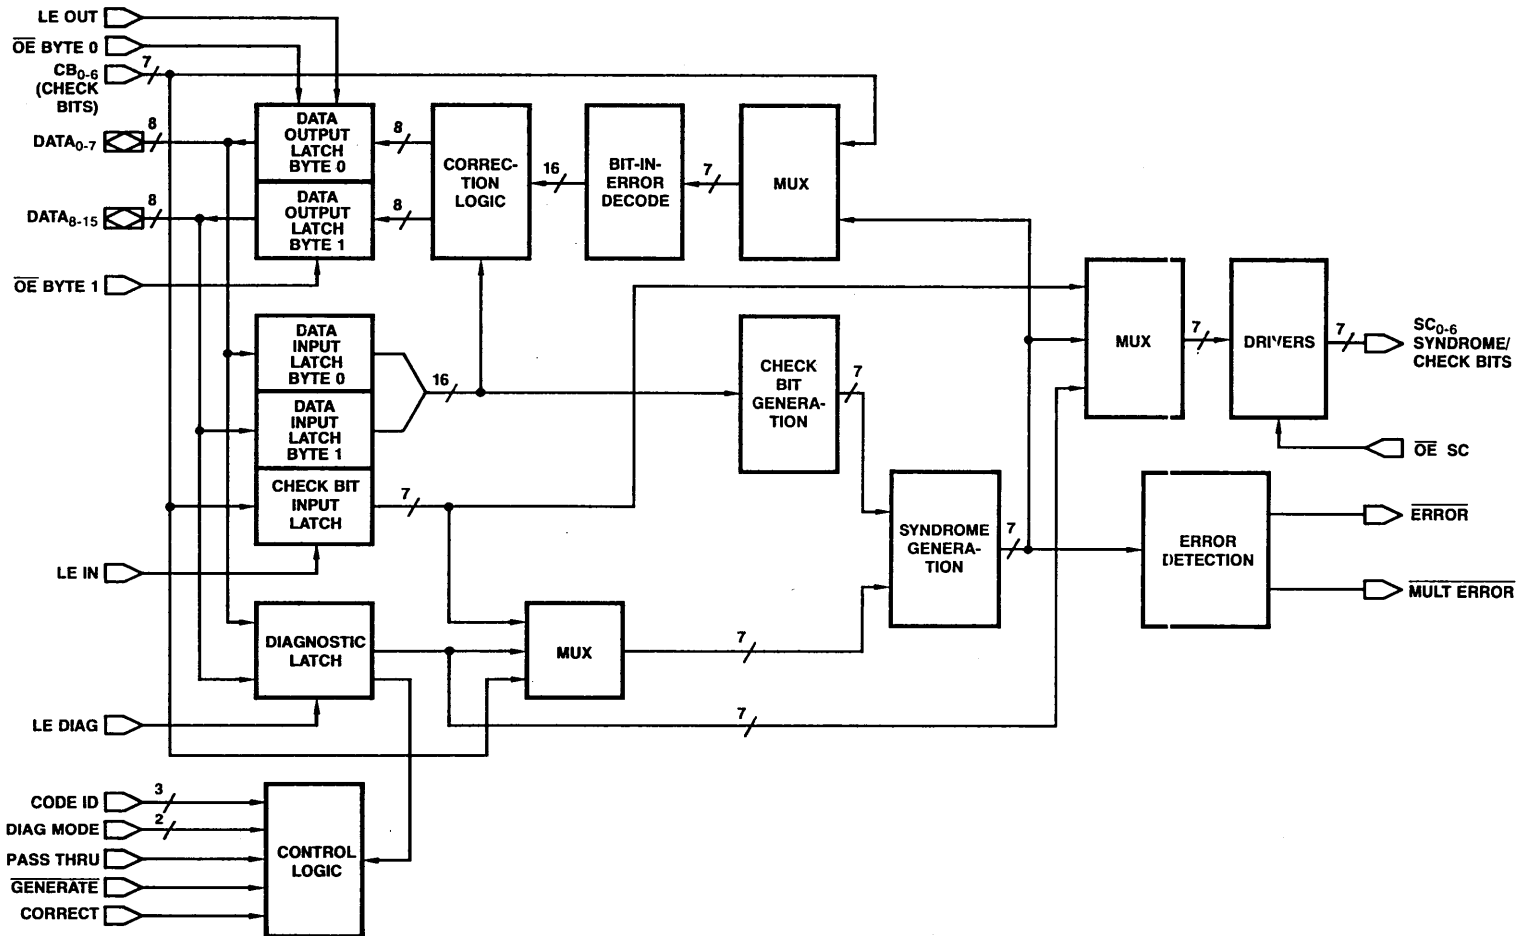

GENERAL DESCRIPTION

The AmZ8160 Error Detection and Correction Unit (EDC) contains the logic necessary to generate 6 check bits on a 16-bit data field according to a modified Hamming Code, and to correct the data word when check bits are supplied. Operating on data read from memory, the AmZ8160 will correct any single bit error and will detect all double on some triple bit errors. The AmZ8160 is expandable to operate on 32-bit words (7 check bits) and 64-bit words (8 check bits). In all configurations, the device makes the error syndrome available on separate outputs for data logging.

The AmZ8160 also features two diagnostic modes, in which diagnostic data can be forced into portions of the chip to simplify device testing and to execute system diagnostic functions. The product is supplied in a 48 lead hermetic DIP package.

SYSTEM EXAMPLE

BLOCK DIAGRAM

EDC Architecture

The EDC Unit is a powerful 16-bit cascadable slice used for check bit generation, error detection, error correction and diagnostics.

As shown in the block diagram, the device consists of the following:

- Data Input Latch
- Check Bit Input Latch
- Check Bit Generation Logic
- Syndrome Generation Logic
- Error Detection Logic
- Error Correction Logic
- Data Output Latch
- Diagnostic Latch
- Control Logic

Data Input Latch

16 bits of data are loaded from the bidirectional DATA lines under control of the Latch Enable input, LE IN. Depending on the control mode the input data is either used for check bit generation or error detection/correction.

Check Bit Input Latch

Seven check bits are loaded under control of LE IN. Check bits are used in the Error Detection and Error Correction modes.

Check Bit Generation Logic

This block generates the appropriate check bits for the 16 bits of data in the Data Input Latch. The check bits are generated according to a modified Hamming code.

Syndrome Generation Logic

In both Error Detection and Error Correction modes, this logic block compares the check bits read from memory against a newly generated set of check bits produced for the data read in from memory. If both sets of check bits match, then there are no errors. If there is a mismatch, then one or more of the data or check bits is in error.

The syndrome bits are produced by an exclusive-OR of the two sets of check bits. If the two sets of check bits are identical

(meaning there are no errors) the syndrome bits will be all zeroes. If there are errors, the syndrome bits can be decoded to determine the number of errors and the bit-in-error.

Error Detection Logic

This section decodes the syndrome bits generated by the Syndrome Generation Logic. If there are no errors in either the input data or check bits, the $\overline{\text{ERROR}}$ and $\overline{\text{MULTI ERROR}}$ outputs remain HIGH. If one or more errors are detected, $\overline{\text{ERROR}}$ goes LOW. If two or more errors are detected, both $\overline{\text{ERROR}}$ and $\overline{\text{MULTI ERROR}}$ go LOW.

Error Correction Logic

For single errors, the Error Correction Logic complements (corrects) the single data bit in error. This corrected data is loadable into the Data Output Latch, which can then be read onto the bidirectional data lines. If the single error is one of the check bits, the correction logic does not place corrected check bits on the syndrome/check bit outputs. If the corrected check bits are needed the EDC must be switched to Generate Mode.

Data Output Latch

The Data Output Latch is used for storing the result of an error correction operation. The latch is loaded from the correction logic under control of the Data Output Latch Enable, LE OUT. The Data Output Latch may also be loaded directly from the Data Input Latch under control of the PASS THRU control input.

The Data Output Latch is split into two 8-bit (byte) latches which may be enabled independently for reading onto the bidirectional data lines.

Diagnostic Latch

This is a 16-bit latch loadable from the bidirectional data lines under control of the Diagnostic Latch Enable, LE DIAG. The Diagnostic Latch contains check bit information in one byte and control information in the other byte. The Diagnostic Latch is used for driving the device when in Internal Control Mode, or for supplying check bits when in one of the Diagnostic Modes.

Control Logic

The control logic determines the specific mode the device operates in. Normally the control logic is driven by external control inputs. However, in Internal Control Mode, the control signals are instead read from the Diagnostic Latch.

PIN DEFINITIONS

DATA₀₋₁₅	16 bidirectional data lines. They provide input to the Data Input Latch and Diagnostic Latch, and receive output from the Data Output Latch. DATA ₀ is the least significant bit; DATA ₁₅ the most significant.	CORRECT	Correct input. When HIGH this signal allows the correction network to correct any single-bit error in the Data Input Latch (by complementing the bit-in-error) before putting it onto the Data Output Latch. When LOW the EDC will drive data directly from the Data Input Latch to the Data Output Latch without correction.
CB₀₋₆	Seven Check Bit input lines. The check bit lines are used to input check bits for error detection. Also used to input syndrome bits for error correction in 32 and 64-bit configurations.	LE OUT	Latch Enable – Data Output Latch. Controls the latching of the Data Output Latch. When LOW the Data Output Latch is latched to its previous state. When HIGH the Data Output Latch follows the output of the Data Input Latch as modified by the correction logic network. In Correct Mode, single-bit errors are corrected by the network before loading into the Data Output Latch. In Detect Mode, the contents of the Data Input Latch are passed through the correction network unchanged into the Data Output Latch. The inputs to the Data Output Latch are unspecified if the EDC is in Generate Mode.
LE IN	Latch Enable – Data Input Latch. Controls latching of the input data. When HIGH the Data Input Latch and Check Bit Input Latch follow the input data and input check bits. When LOW, the Data Input Latch and Check Bit Input Latch are latched to their previous state.	OE BYTE 0, OE BYTE 1	Output Enable – Bytes 0 and 1, Data Output Latch. These lines control the 3-state outputs for each of the two bytes of the Data Output Latch. When LOW these lines enable the Data Output Latch and when HIGH these lines force the Data Output Latch into the high impedance state. The two enable lines can be separately activated to enable only one byte of the Data Output Latch at a time.
GENERATE	Generate Check Bits input. When this input is LOW the EDC is in the Check Bit Generate Mode. When HIGH the EDC is in the Detect Mode or Correct Mode. In the Generate Mode the circuit generates the check bits or partial check bits specific to the data in the Data Input Latch. The generated check bits are placed on the SC outputs. In the Detect or Correct Modes the EDC detects single and multiple errors, and generates syndrome bits based upon the contents of the Data Input Latch and Check Bit Input Latch. In Correct Mode, single-bit errors are also automatically corrected – corrected data is placed at the inputs of the Data Output Latch. The syndrome result is placed on the SC outputs and indicates in a coded form the number of errors and the bit-in-error.	PASS THRU	Pass Thru input. This line when HIGH forces the contents of the Check Bit Input Latch onto the Syndrome/Check Bit outputs (SC ₀₋₆) and the unmodified contents of the Data Input Latch onto the inputs of the Data Output Latch.
SC₀₋₆	Syndrome/Check Bit outputs. These seven lines hold the check/partial-check bits when the EDC is in Generate Mode, and will hold the syndrome/partial syndrome bits when the device is in Detect or Correct Modes. These are 3-state outputs.	DIAG MODE₀₋₁	Diagnostic Mode Select. These two lines control the initialization and diagnostic operation of the EDC.
OE SC	Output Enable – Syndrome/Check Bits. When LOW, the 3-state output lines SC ₀₋₆ are enabled. When HIGH, the SC outputs are in the high impedance state.	CODE ID₀₋₂	Code Identification inputs. These three bits identify the size of the total data word to be processed and which 16-bit slice of larger data words a particular EDC is processing. The three allowable data word sizes are 16, 32 and 64 bits and their respective modified Hamming codes are designated 16/22, 32/39 and 64/72. Special CODE ID input 001 (ID ₂ , ID ₁ , ID ₀) is also used to instruct the EDC that the signals CODE ID ₀₋₂ , DIAG MODE ₀₋₁ , CORRECT and PASS THRU are to be taken from the Diagnostic Latch, rather than from the input control lines.
ERROR	Error Detected output. When the EDC is in Detect or Correct Mode, this output will go LOW if one or more syndrome bits are asserted, meaning there are one or more bit errors in the data or check bits. If no syndrome bits are asserted, there are no errors detected and the output will be HIGH. In Generate Mode, ERROR is forced HIGH. (In a 64-bit configuration, ERROR must be externally implemented.)	LE DIAG	Latch Enable – Diagnostic Latch. When HIGH the Diagnostic Latch follows the 16-bit data on the input lines. When LOW the outputs of the Diagnostic Latch are latched to their previous states. The Diagnostic Latch holds diagnostic check bits, and internal control signals for CODE ID ₀₋₂ , DIAG MODE ₀₋₁ , CORRECT and PASS THRU.
MULTI ERROR	Multiple Errors Detected output. When the EDC is in Detect or Correct Mode, this output if LOW indicates that there are two or more bit errors that have been detected. If HIGH this indicates that either one or no errors have been detected. In		

FUNCTIONAL DESCRIPTION

The EDC contains the logic necessary to generate check bits on a 16-bit data field according to a modified Hamming code. Operating on data read from memory, the EDC will correct any single-bit error, and will detect all double and some triple-bit errors. It may be configured to operate on 16-bit data words (with 6 check bits), 32-bit data words (with 7 check bits) and 64-bit data words (with 8 check bits). In all configurations, the device makes the error syndrome bits available on separate outputs for error data logging.

Code and Byte Specification

The EDC may be configured in several different ways and operates differently in each configuration. It is necessary to indicate to the device what size data word is involved and which bytes of the data word it is processing. This is done with input lines CODE ID₀₋₂, as shown in Table I. The three modified Hamming codes referred to in Table I are:

- 16/22 code – 16 data bits
– 6 check bits
– 22 bits in total.
- 32/39 code – 32 data bits
– 7 check bits
– 39 bits in total.
- 64/72 code – 64 data bits
– 8 check bits
– 72 bits in total.

CODE ID input 001 (ID₂, ID₁, ID₀) is a special code used to operate the device in Internal Control Mode (described later in this section).

TABLE I. HAMMING CODE AND SLICE IDENTIFICATION.

CODE ID ₂	CODE ID ₁	CODE ID ₀	Hamming Code and Slice Selected
0	0	0	Code 16/22
0	0	1	Internal Control Mode
0	1	0	Code 32/39, Bytes 0 and 1
0	1	1	Code 32/39, Bytes 2 and 3
1	0	0	Code 64/72, Bytes 0 and 1
1	0	1	Code 64/72, Bytes 2 and 3
1	1	0	Code 64/72, Bytes 4 and 5
1	1	1	Code 64/72, Bytes 6 and 7

Control Mode Selection

The device control lines are GENERATE, CORRECT, PASS THRU, DIAG MODE₀₋₁ and CODE ID₀₋₂. Table II indicates the control modes selected by various combinations of the control line inputs.

Diagnostics

Table III shows specifically how DIAG MODE₀₋₁ select between normal operation, initialization and one of two diagnostic modes.

The Diagnostic Modes allow the user to operate the EDC under software control in order to verify proper functioning of the device.

Check and Syndrome Bit Labeling

The check bits generated in the EDC are designated as follows:

- 16-bit configuration – CX C0, C1, C2, C4, C8;
- 32-bit configuration – CX, C0, C1, C2, C4, C8, C16;
- 64-bit configuration – CX, C0, C1, C2, C4, C8, C16, C32.

Syndrome bits are similarly labeled SX through S32. There are only 6 syndrome bits in the 16-bit configuration, 7 for 32 bits and 8 syndrome bits in the 64-bit configuration.

FUNCTIONAL DESCRIPTION – 16-BIT DATA WORD CONFIGURATION

The 16-bit format consists of 16 data bits, 6 check bits and is referred to as 16/22 code (see Figure 1).

The 16-bit configuration is shown in Figure 2.

Generate Mode

In this mode check bits will be generated that correspond to the contents of the Data Input Latch. The check bits generated are placed on the outputs SC₀₋₅ (SC₆ is unspecified for 16-bit operation).

Check bits are generated according to a modified Hamming code. Details of the code for check bit generation are contained in Table IV. Each check bit is generated as either an XOR or XNOR of eight of the 16 data bits as indicated in the table. The XOR function results in an even parity check bit, the XNOR is an odd parity check bit.

Detect Mode

In this mode the device examines the contents of the Data Input Latch against the Check Bit Input Latch, and will detect all single-bit errors, all double-bit errors and some triple-bit errors. If one or more errors are detected, ERROR goes LOW. If two or more errors are detected, MULTI ERROR goes LOW. Both error indicators are HIGH if there are no errors.

Also available on device outputs SC₀₋₅ are the syndrome bits generated by the error detection step. The syndrome bits may be decoded to determine if a bit error was detected and, for single-bit errors, which of the data or check bits is in error. Table V gives the chart for decoding the syndrome bits generated by the 16-bit configuration (as an example, if the syndrome bits SX/S0/S1/S2/S4/S8 were 101001 this would be decoded to indicate that there is a single-bit error at data bit 9). If no error is detected the syndrome bits will all be zeroes.

In Detect Mode, the contents of the Data Input Latch are driven directly to the inputs of the Data Output Latch without correction.

Correct Mode

In this mode, the EDC functions the same as in Detect Mode except that the correction network is allowed to correct (complement) any single-bit error of the Data Input Latch before putting it onto the inputs of the Data Output Latch. If multiple errors are detected, the output of the correction network is unspecified. If the single-bit error is a check bit there is no automatic correction. If check bit correction is desired, this can be done by placing the device in Generate Mode to produce a correct check bit sequence for the data in the Data Input Latch.

Pass Thru Mode

In this mode, the unmodified contents of the Data Input Latch are placed on the inputs of the Data Output Latch and the contents of the Check Bit Input Latch are placed on outputs SC₀₋₅.

15	Don't Care

Diagnostic Latch

The Diagnostic Latch serves both for diagnostic uses and internal control uses. It is loaded from the DATA lines under the control of LE DIAG. Table VI shows the loading definitions for the DATA lines.

Generate Using Diagnostic Latch (Diagnostic Mode A)

Detect Using Diagnostic Latch (Diagnostic Mode B)

Correct Using Diagnostic Latch (Diagnostic Mode B)

These are special diagnostic modes selected by DIAG MODE₀₋₁ where either normal check bit inputs or outputs are substituted for by check bits loaded into the Diagnostic Latch. See Table III for details.

Internal Control Mode

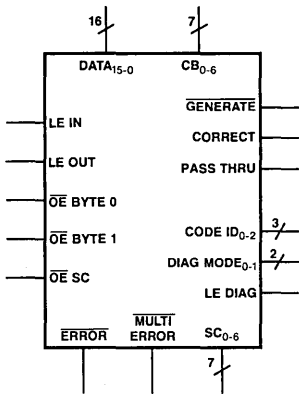

This mode is selected by CODE ID₀₋₂ input 001 (ID₂, ID₁, ID₀). When in Internal Control Mode, the EDC takes the CODE ID₀₋₂, DIAG MODE₀₋₁, CORRECT and PASS THRU control signals from the internal Diagnostic Latch rather than from the external input lines.

Table VI gives the format for loading the Diagnostic Latch.

32 and 64-Bit Operation

The EDC can easily be cascaded to operate on 32 and 64-bit data words. Since this is unlikely to occur in a Z8000 system, it is not discussed in this data sheet. Interested users should refer to the Am2960 data sheet for more information.

AmZ8161 • AmZ8162

4-Bit Error Correction Multiple Bus Buffers

IN DEVELOPMENT

DISTINCTIVE CHARACTERISTICS

- Quad high-speed LSI bus-transceiver
- Provides complete data path interface between the AmZ8160 Error Detection and Correction Unit, the system data bus and dynamic RAM memory
- 3-state 24mA output to data bus
- 3-state data output to memory
- Inverting data bus for AmZ8161 and non-inverting for AmZ8162
- Data bus latches allow operation with multiplexed buses
- Advanced Low-Power Schottky processing
- 100% product assurance screening to MIL-STD-883 requirements

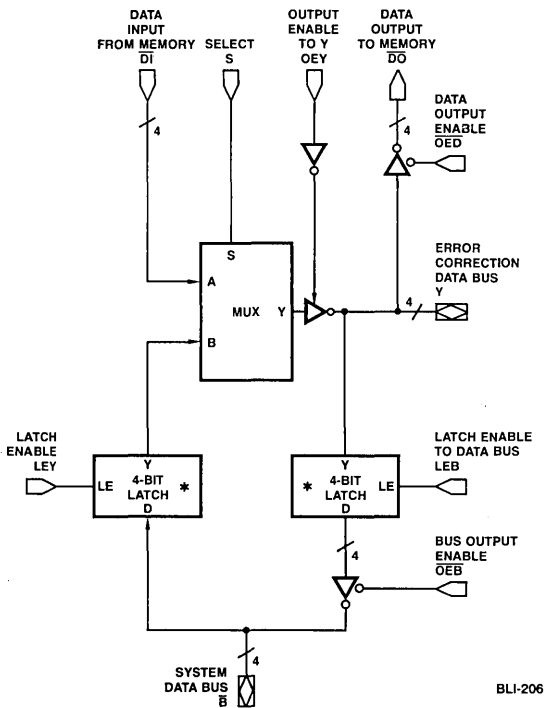

FUNCTIONAL DESCRIPTION

The AmZ8161 and AmZ8162 are high-performance, low-power Schottky multiple bus buffers that provide the complete data path interface between the AmZ8160 Error Detection and Correction Unit, dynamic RAM memory and the AmZ8000 system data bus. The AmZ8161 provides an inverting data path between the data bus (\bar{B}_i) and the AmZ8160 error correction data input (Y_i) and the AmZ8162 provides a non-inverting configuration (B_i to Y_i). Both devices provide inverting data paths between the AmZ8160 and memory data bus thereby optimizing internal data path speeds.

The AmZ8161 and AmZ8162 are 4-bit devices. Four devices are used to interface each 16-bit AmZ8160 Error Detection and Correction Unit with dynamic memory. The system can easily be expanded to 32 or more bits for wider memory applications. The 4-bit configuration allows enabling the appropriate devices two-at-a-time for intermixed word or byte, read and write in 16-bit systems with error correction.

Data latches between the error correction data bus and the system data bus facilitate the addition of error corrected memory in synchronous data bus systems. They also provide a data holding capability during single-step system operation.

AmZ8161 LOGIC DIAGRAM

BLI-206

*AmZ8162 is the same function but non-inverting between the Y bus to the system data bus, B. This is done by making both latches inverting.

AmZ8163

Dynamic Memory Timing, Refresh and EDC Controller

DISTINCTIVE CHARACTERISTICS

- Complete AmZ8000 CPU to dynamic RAM control interface
- RAS/CAS Sequencer to eliminate delay lines
- Memory request/refresh arbitration
- Controls for Word/Byte read or write
- Complete EDC data path and mode controls
- Refresh interval timer independent of CPU
- Refresh control during Single Step or Halt modes
- EDC error flag latches for error logging under software control
- Also, complete control for 8-Bit MOS μ P

FUNCTIONAL DESCRIPTION

The AmZ8163 is a high speed bus interface controller forming an integral part of the AmZ8000 memory support chip set using dynamic MOS RAMs with Error Detection and Correction (EDC). The complete chip set includes the AmZ8127 Clock Generator and Controller, the AmZ8164 Dynamic Memory Controller, the AmZ8161/2 EDC Bus Buffers, the AmZ8160 EDC Unit and optional AmZ8165/6 RAM Drivers.

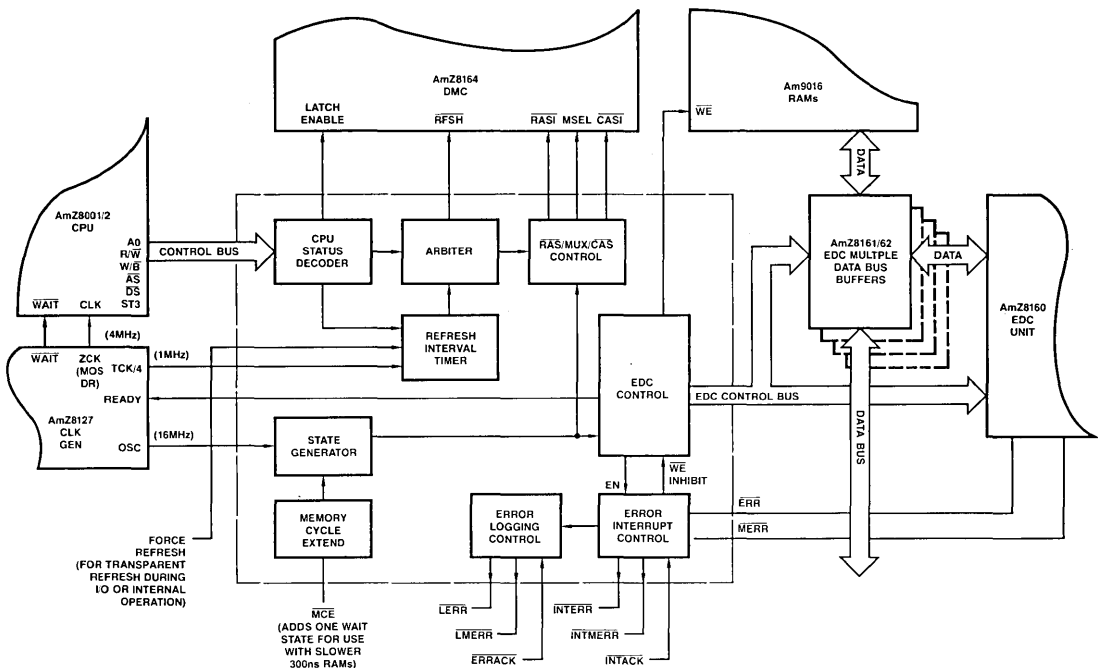

The AmZ8163 provides all of the control interface functions including RAS/Address MUX/CAS timing (without delay lines), refresh timing, memory request/refresh arbitration and all EDC

enables and controls. The enable controls are configured for both word and byte operations including the data controls for byte write with error correction. The AmZ8163 generates bus and operating mode controls for the AmZ8160 EDC Unit.

The AmZ8163 uses the AmZ8127 16MHz (4 x CLK) output to generate RAS/Address MUX/CAS timing. An internal refresh interval timer generates the memory refresh request independent of the CPU to guarantee the proper refresh timing under all combinations of CPU and DMA memory requests.

4

FUNCTION DIAGRAM REFRESH AND EDC CONTROLLER

AmZ8164

Dynamic Memory Controller

DISTINCTIVE CHARACTERISTICS

- Dynamic Memory Controller for 16K and 64K MOS dynamic RAMs
- 8-Bit Refresh Counter for refresh address generation, has clear input and terminal count output
- Refresh Counter Terminal count selectable at 256 or 128
- Latch Input RAS Decoder provides 4 RAS outputs, all active during refresh
- Dual 8-Bit Address Latches plus separate $\overline{\text{RAS}}$ Decoder Latches
- Grouping functions on a common chip minimizes speed differential/skew between address, $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ outputs
- 3-Port 8-Bit Address Multiplexer with Schottky speed
- Burst mode, distributed refresh or transparent refresh mode determined by user
- Non-inverting address, $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ paths
- 100% product assurance screening to MIL-STD-883 requirements

FUNCTIONAL DESCRIPTION

The AmZ8164 Dynamic Memory Controller replaces several MSI devices by grouping several unique functions. Two 8-bit latches capture and hold the memory address from the AmZ8000 multiplexed data and address bus. These latches and a clearable, 8-bit refresh counter feed into an 8-bit, 3-input, Schottky speed MUX, for output to the dynamic RAM address lines. The device is also compatible with Am8085 or any CPU interfacing with dynamic RAMs.

The same silicon chip also includes a special RAS decoder and CAS buffer. Placing these functions on the same chip minimizes the time skew between output functions which would otherwise be separate MSI chips, and therefore, allows a faster memory cycle time by the amount of skew eliminated.

Pulsing the active LOW refresh line, $\overline{\text{RFSH}}$, switches the MUX to the counter output, inhibits $\overline{\text{CAS}}$, and forces all four $\overline{\text{RAS}}$ decoder outputs active simultaneously. The counter is advanced at the end of the refresh cycle – the LOW-to-HIGH transition of $\overline{\text{RFSH}}$. Various refresh modes can be accommodated – for 16K or 64K RAMs and for a wide variety of processor configurations.

A_{15} is a dual function input which controls the refresh counter's range. For 64K RAMs it is an address input. For 16K RAMs it can be pulled to +12V through 1K Ω to terminate the refresh count at 128 instead of 256 if this is needed.

BLI-209

AmZ8165 • AmZ8166

Octal Dynamic Memory Drivers with Three-State Outputs

DISTINCTIVE CHARACTERISTICS

- Controlled rise and fall characteristics**
 Internal resistors provide symmetrical drive to HIGH and LOW states, eliminating need for external series resistor.
- Output swings designed to drive 16K and 64K RAMs**
 V_{OH} guaranteed at $V_{CC} - 1.15V$. Undershoot going LOW guaranteed at less than 0.5V.
- Large capacitive drive capability**
 35mA min source or sink current at 2.0V. Propagation delays specified for 50pF and 500pF loads.
- Pin-compatible with 'S240 and 'S244**
 Non-inverting AmZ8166 replaces 74S244; inverting AmZ8165 replaces 74S240. Faster than 'S240/244 under equivalent load.
- No-glitch outputs**
 Outputs forced into OFF state during power up and down.

FUNCTIONAL DESCRIPTION

The AmZ8165 and AmZ8166 are designed and specified to drive the capacitive input characteristics of the address and control lines of MOS dynamic RAMs. The unique design of the lower output driver includes a collector resistor to control undershoot on the HIGH-to-LOW transition. The upper output driver pulls up to $V_{CC} - 1.15V$ to be compatible with MOS memory and is designed to have a rise time symmetrical with the lower output's controlled fall time. This allows optimization of Dynamic RAM performance.

The AmZ8165 and AmZ8166 are pin-compatible with the popular 'S240 and 'S244 with identical 3-state output enable controls. The AmZ8165 has inverting drivers and the AmZ8166 has non-inverting drivers.

The inclusion of an internal resistor in the lower output driver eliminates the requirement for an external series resistor, therefore reducing package count and the board area required. The internal resistor controls the output fall and undershoot without slowing the output rise.

These devices are designed for use with the AmZ8164 Dynamic Memory Controller where large dynamic memories with highly capacitive input lines require additional buffering. Driving eight address lines or four \overline{RAS} and four \overline{CAS} lines with drivers on the same silicon chip also provides a significant performance advantage by minimizing skew between drivers. Each device has specified skew between drivers to improve the memory access worst case timing over the min and max t_{PD} difference of unspecified devices.

TYPICAL SWITCHING CHARACTERISTICS

VOLTAGE WAVEFORMS

Figure 3. Output Drive Levels.

Figure 4. Three-State Control Levels.

The RAM Driver symmetrical output design offers significant improvement over a standard Schottky output by providing a balanced drive output impedance ($\approx 33\Omega$ both HIGH and LOW), and by pulling up to MOS V_{OH} levels ($V_{CC} - 1.15V$). External resistors, not required with the RAM Driver, protect standard Schottky drivers from error causing undershoot but also slow the output rise by adding to the internal R.

The RAM Driver is optimized to drive LOW at maximum speed based on safe undershoot control and to drive HIGH with a symmetrical speed characteristic. This is an optimum approach because the dominant RAM loading characteristic is input capacitance.

The curves shown below provide performance characteristics typical of both the inverting (AmZ8165) and non-inverting (AmZ8166) RAM Drivers.

BLI-220

Figure 6. t_{PHL} vs. C_L .

The curves above depict the typical t_{PLH} and t_{PHL} for the RAM Driver outputs as a function of load capacitance. The minimums and maximums are shown for worst case design. The typical band is provided as a guide for intermediate capacitive loads.

APPLICATION

BLI-221

*Address and $\overline{\text{RAS}}/\overline{\text{CAS}}$ drivers each drive 22 RAM inputs at each output. Timing skew is minimized by using one device for address lines and one device for $\overline{\text{RAS}}/\overline{\text{CAS}}$, spreading the $\overline{\text{CAS}}$ loading over four drivers to equalize the capacitive load on each driver.

Am8255A/8255A-5

Programmable Peripheral Interface

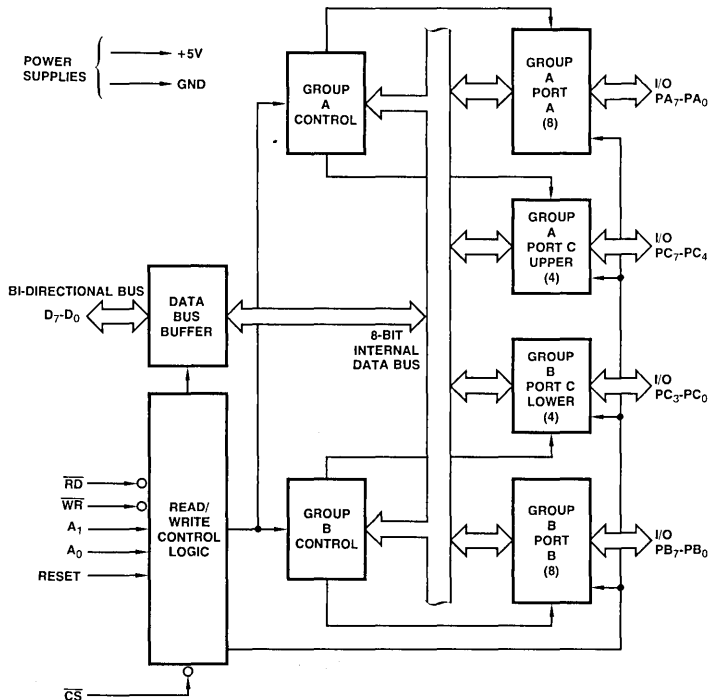

DISTINCTIVE CHARACTERISTICS

- Direct bit set/reset capability easing control application interface
- Reduces system package count
- Improved DC driving capability
- 24 programmable I/O pins
- Completely TTL compatible
- Fully compatible with 8080A and 8085A microprocessor families
- Improved timing characteristics
- Military version available

GENERAL DESCRIPTION

The Am8255A is a general purpose programmable I/O device designed for use with Am8080A and Am8085A microprocessors. It has 24 I/O pins which may be individually programmed in two groups of twelve and used in three major modes of operation. In the first mode, each group of twelve I/O pins may be programmed in sets of 4 and 8 to be input or output. In Mode 1, the second mode, each group may be programmed to have 8 lines of input or output. Of the remaining four pins three are used for handshaking and interrupt control signals. The third mode of operation (Mode 2) is a bi-directional bus mode which uses eight lines for a bi-directional bus, and five lines, borrowing one from the other group, for handshaking.

Am9511A

Arithmetic Processor

DISTINCTIVE CHARACTERISTICS

- Replaces Am9511
- Fixed point 16 and 32 bit operations
- Floating point 32 bit operations
- Binary data formats
- Add, Subtract, Multiply and Divide
- Trigonometric and inverse trigonometric functions
- Square roots, logarithms, exponentiation
- Float to fixed and fixed to float conversions
- Stack-oriented operand storage
- DMA or programmed I/O data transfers
- End signal simplifies concurrent processing
- Synchronous/Asynchronous operations
- General purpose 8-bit data bus interface
- Standard 24 pin package
- +12 volt and +5 volt power supplies
- Advanced N-channel silicon gate MOS technology
- 100% MIL-STD-883 reliability assurance testing

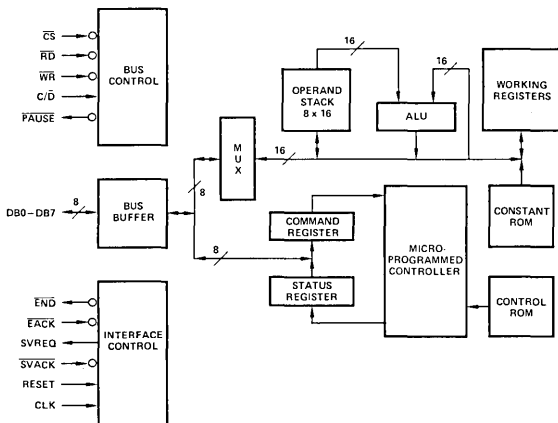

GENERAL DESCRIPTION

The Am9511A Arithmetic Processing Unit (APU) is a monolithic MOS/LSI device that provides high performance fixed and floating point arithmetic and a variety of floating point trigonometric and mathematical operations. It may be used to enhance the computational capability of a wide variety of processor-oriented systems.

All transfers, including operand, result, status and command information, take place over an 8-bit bidirectional data bus. Operands are pushed onto an internal stack and a command is issued to perform operations on the data in the stack. Results are then available to be retrieved from the stack, or additional commands may be entered.

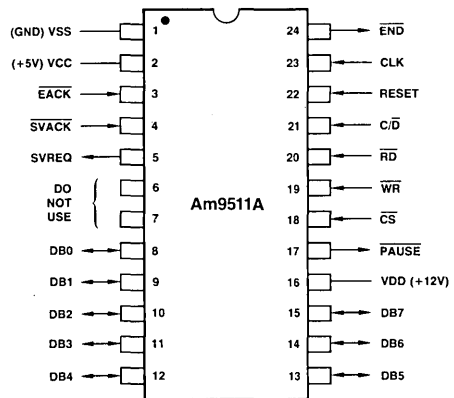

Transfers to and from the APU may be handled by the associated processor using conventional programmed I/O, or may be handled by a direct memory access controller for improved performance. Upon completion of each command, the APU issues an end of execution signal that may be used as an interrupt by the CPU to help coordinate program execution.

INTERFACE SIGNAL DESCRIPTION

VCC: +5V Power Supply
VDD: +12V Power Supply
VSS: Ground

CLK (Clock, Input)

An external timing source connected to the CLK input provides the necessary clocking. The CLK input can be asynchronous to the \overline{RD} and \overline{WR} control signals.

RESET (Reset, Input)

A HIGH on this input causes initialization. Reset terminates any operation in progress, and clears the status register to zero. The internal stack pointer is initialized and the contents of the stack may be affected but the command register is not affected by the reset operation. After a reset the \overline{END} output, and the SVREQ output will be LOW. For proper initialization, the RESET input must be HIGH for at least five CLK periods following stable power supply voltages and stable clock.

C/D (Command/Data Select, Input)

The C/D input together with the \overline{RD} and \overline{WR} inputs determines the type of transfer to be performed on the data bus as follows:

C/D	\overline{RD}	\overline{WR}	Function
L	H	L	Push data byte into the stack
L	L	H	Pop data byte from the stack
H	H	L	Enter command byte from the data bus
H	L	H	Read Status
X	L	L	Undefined

L = LOW
H = HIGH
X = DON'T CARE

 \overline{END} (End of Execution, Output)

A LOW on this output indicates that execution of the current command is complete. This output will be cleared HIGH by activating the \overline{EACK} input LOW or performing any read or write operation or device initialization using the RESET. If \overline{EACK} is tied LOW, the \overline{END} output will be a pulse (see \overline{EACK} description). This is an open drain output and requires a pull up to +5V.

Reading the status register while a command execution is in progress is allowed. However any read or write operation clears the flip-flop that generates the \overline{END} output. Thus such continuous reading could conflict with internal logic setting the \overline{END} flip-flop at the completion of command execution.

 \overline{EACK} (End Acknowledge, Output)

This input when LOW makes the \overline{END} output go LOW. As mentioned earlier HIGH on the \overline{END} output signals completion of a command execution. The \overline{END} output signal is derived from an internal flip-flop which is clocked at the completion of a command. This flip-flop is clocked to the reset state when \overline{EACK} is LOW. Consequently, if the \overline{EACK} is tied LOW, the \overline{END} output will be a pulse that is approximately one CLK period wide.

SVREQ (Service Request, Output)

A HIGH on this output indicates completion of a command. In this sense this output is same as the \overline{END} output. However, whether the SVREQ output will go HIGH at the completion of a command or not is determined by a service request bit in the command register. This bit must be 1 for SVREQ to go HIGH. The SVREQ can be cleared (i.e., go LOW) by activating the SVACK input LOW or initializing the device using the RESET.

Also, the SVREQ will be automatically cleared after completion of any command that has the service request bit as 0.

SVACK (Service Acknowledge, Input)

A LOW on this input activates the reset input of the flip-flop generating the SVREQ output. If the SVACK input is permanently tied LOW, it will conflict with the internal setting of the flip-flop to generate the SVREQ output. Thus the SVREQ indication cannot be relied upon if the SVACK is tied LOW.

DB0-DB7 (Bidirectional Data Bus, Input/Output)

These eight bidirectional lines are used to transfer command, status and operand information between the device and the host processor. DB0 is the least significant and DB7 is the most significant bit position. HIGH on the data bus line corresponds to 1 and LOW corresponds to 0.

When pushing operands on the stack using the data bus, the least significant byte must be pushed first and most significant byte last. When popping the stack to read the result of an operation, the most significant byte will be available on the data bus first and the least significant byte will be the last. Moreover, for pushing operands and popping results, the number of transactions must be equal to the proper number of bytes appropriate for the chosen format. Otherwise, the internal byte pointer will not be aligned properly. The Am9511A single precision format requires 2 bytes, double precision and floating-point formats require 4 bytes.

 \overline{CS} (Chip Select, Input)

This input must be LOW to accomplish any read or write operation to the Am9511A.

To perform a write operation data is presented on DB0 through DB7 lines, C/D is driven to an appropriate level and the \overline{CS} input is made LOW. However, actual writing into the Am9511A cannot start until \overline{WR} is made LOW. After initiating the write operation by a \overline{WR} HIGH to LOW transition, the PAUSE output will go LOW momentarily (TPPWW).

The \overline{WR} input can go HIGH after \overline{PAUSE} goes HIGH. The data lines, C/D input and the \overline{CS} input can change when appropriate hold time requirements are satisfied. See write timing diagram for details.

To perform a read operation an appropriate logic level is established on the C/D input and \overline{CS} is made LOW. The Read operation does not start until the \overline{RD} input goes LOW. PAUSE will go LOW for a period of TPPWR. When \overline{PAUSE} goes back HIGH again, it indicates that read operation is complete and the required information is available on the DB0 through DB7 lines. This information will remain on the data lines as long as \overline{RD} input is LOW. The \overline{RD} input can return HIGH anytime after \overline{PAUSE} goes HIGH. The \overline{CS} input and C/D inputs can change anytime after \overline{RD} returns HIGH. See read timing diagram for details. The \overline{CS} must have a HIGH to LOW transition for every READ or WRITE operation.

 \overline{RD} (Read, Input)

A LOW on this input is used to read information from an internal location and gate that information on to the data bus. The \overline{CS} input must be LOW to accomplish the read operation. The C/D input determines what internal location is of interest. See C/D, \overline{CS} input descriptions and read timing diagram for details. If the \overline{END} output was LOW, performing any read operation will make the \overline{END} output go HIGH after the HIGH to LOW transition of the \overline{RD} input (assuming \overline{CS} is LOW).

\overline{WR} (Write, Input)

A LOW on this input is used to transfer information from the data bus into an internal location. The \overline{CS} must be LOW to accomplish the write operation. The C/\overline{D} determines which internal location is to be written. See C/\overline{D} , \overline{CS} input descriptions and write timing diagram for details.

If the \overline{END} output was LOW, performing any write operation will make the \overline{END} output go HIGH after the LOW to HIGH transition of the \overline{WR} input (assuming \overline{CS} is LOW).

 \overline{PAUSE} (Pause, Output)

This output is a handshake signal used while performing read or write transactions with the Am9511A. A LOW at this output indicates that the Am9511A has not yet completed its information transfer with the host over the data bus. During a read operation, after \overline{CS} went LOW, the \overline{PAUSE} will become LOW shortly (TRP) after \overline{RD} goes LOW. \overline{PAUSE} will return high only after the data bus contains valid output data. The \overline{CS} and \overline{RD} should remain LOW when \overline{PAUSE} is LOW. The \overline{RD} may go high anytime after \overline{PAUSE} goes HIGH. During a write operation, after \overline{CS} went LOW, the \overline{PAUSE} will be LOW for a very short duration (TPPW) after \overline{WR} goes LOW. Since the minimum of TPPWW is 0, the \overline{PAUSE} may not go LOW at all for fast devices. \overline{WR} may go HIGH anytime after \overline{PAUSE} goes HIGH.

FUNCTIONAL DESCRIPTION

Major functional units of the Am9511A are shown in the block diagram. The Am9511A employs a microprogram controlled stack oriented architecture with 16-bit wide data paths.

The Arithmetic Logic Unit (ALU) receives one of its operands from the Operand Stack. This stack is an 8-word by 16-bit 2-port memory with last in-first out (LIFO) attributes. The second operand to the ALU is supplied by the internal 16-bit bus. In addition to supplying the second operand, this bidirectional bus also carries the results from the output of the ALU when required. Writing into the Operand Stack takes place from this internal 16-bit bus when required. Also connected to this bus are the Constant ROM and Working Registers. The ROM provides the required constants to perform the mathematical operations (Chebyshev Algorithms) while the Working Registers provide storage for the intermediate values during command execution.

Communication between the external world and the Am9511A takes place on eight bidirectional input/output lines DB0 through DB7 (Data Bus). These signals are gated to the internal eight-bit

bus through appropriate interface and buffer circuitry. Multiplexing facilities exist for bidirectional communication between the internal eight and sixteen-bit buses. The Status Register and Command Register are also accessible via the eight-bit bus.

The Am9511A operations are controlled by the microprogram contained in the Control ROM. The Program Counter supplies the microprogram addresses and can be partially loaded from the Command Register. Associated with the Program Counter is the Subroutine Stack where return addresses are held during subroutine calls in the microprogram. The Microinstruction Register holds the current microinstruction being executed. This register facilitates pipelined microprogram execution. The Instruction Decode logic generates various internal control signals needed for the Am9511A operation.

The Interface Control logic receives several external inputs and provides handshake related outputs to facilitate interfacing the Am9511A to microprocessors.

COMMAND FORMAT

Each command entered into the Am9511A consists of a single 8-bit byte having the format illustrated below:

Bits 0-4 select the operation to be performed as shown in the table. Bits 5-6 select the data format for the operation. If bit 5 is a 1, a fixed point data format is specified. If bit 5 is a 0, floating point format is specified. Bit 6 selects the precision of the data to be operated on by fixed point commands (if bit 5 = 0, bit 6 must be 0). If bit 6 is a 1, single-precision (16-bit) operands are indicated; if bit 6 is a 0, double-precision (32-bit) operands are indicated. Results are undefined for all illegal combinations of bits in the command byte. Bit 7 indicates whether a service request is to be issued after the command is executed. If bit 7 is a 1, the service request output (SVREQ) will go high at the conclusion of the command and will remain high until reset by a low level on the service acknowledge pin (SVACK) or until completion of execution of a succeeding command where bit 7 is 0. Each command issued to the Am9511A requests post execution service based upon the state of bit 7 in the command byte. When bit 7 is a 0, SVREQ remains low.

4

COMMAND SUMMARY

Command Code								Command Mnemonic	Command Description
7	6	5	4	3	2	1	0		
FIXED-POINT 16-BIT									
sr	1	1	0	1	1	0	0	SADD	Add TOS to NOS. Result to NOS. Pop Stack.
sr	1	1	0	1	1	0	1	SSUB	Subtract TOS from NOS. Result to NOS. Pop Stack.
sr	1	1	0	1	1	1	0	SMUL	Multiply NOS by TOS. Lower half of result to NOS. Pop Stack.
sr	1	1	1	0	1	1	0	SMUU	Multiply NOS by TOS. Upper half of result to NOS. Pop Stack.
sr	1	1	0	1	1	1	1	SDIV	Divide NOS by TOS. Result to NOS. Pop Stack.
FIXED-POINT 32-BIT									
sr	0	1	0	1	1	0	0	DADD	Add TOS to NOS. Result to NOS. Pop Stack.
sr	0	1	0	1	1	0	1	DSUB	Subtract TOS from NOS. Result to NOS. Pop Stack.
sr	0	1	0	1	1	1	0	DMUL	Multiply NOS by TOS. Lower half of result to NOS. Pop Stack.
sr	0	1	1	0	1	1	0	DMUU	Multiply NOS by TOS. Upper half of result to NOS. Pop Stack.
sr	0	1	0	1	1	1	1	DDIV	Divide NOS by TOS. Result to NOS. Pop Stack.
FLOATING-POINT 32-BIT									
sr	0	0	1	0	0	0	0	FADD	Add TOS to NOS. Result to NOS. Pop Stack.
sr	0	0	1	0	0	0	1	FSUB	Subtract TOS from NOS. Result to NOS. Pop Stack.
sr	0	0	1	0	0	1	0	FMUL	Multiply NOS by TOS. Result to NOS. Pop Stack.
sr	0	0	1	0	0	1	1	FDIV	Divide NOS by TOS. Result to NOS. Pop Stack.
DERIVED FLOATING-POINT FUNCTIONS									
sr	0	0	0	0	0	0	1	SQRT	Square Root of TOS. Result in TOS.
sr	0	0	0	0	0	1	0	SIN	Sine of TOS. Result in TOS.
sr	0	0	0	0	0	1	1	COS	Cosine of TOS. Result in TOS.
sr	0	0	0	0	1	0	0	TAN	Tangent of TOS. Result in TOS.
sr	0	0	0	0	1	0	1	ASIN	Inverse Sine of TOS. Result in TOS.
sr	0	0	0	0	1	1	0	ACOS	Inverse Cosine of TOS. Result in TOS.
sr	0	0	0	0	1	1	1	ATAN	Inverse Tangent of TOS. Result in TOS.
sr	0	0	0	1	0	0	0	LOG	Common Logarithm (base 10) of TOS. Result in TOS.
sr	0	0	0	1	0	0	1	LN	Natural Logarithm (base e) of TOS. Result in TOS.
sr	0	0	0	1	0	1	0	EXP	Exponential (e^x) of TOS. Result in TOS.
sr	0	0	0	1	0	1	1	PWR	NOS raised to the power in TOS. Result in NOS. Pop Stack.
DATA MANIPULATION COMMANDS									
sr	0	0	0	0	0	0	0	NOP	No Operation
sr	0	0	1	1	1	1	1	FIXS	Convert TOS from floating point to 16-bit fixed point format.
sr	0	0	1	1	1	1	0	FIXD	Convert TOS from floating point to 32-bit fixed point format.
sr	0	0	1	1	1	0	1	FLTS	Convert TOS from 16-bit fixed point to floating point format.
sr	0	0	1	1	1	0	0	FLTD	Convert TOS from 32-bit fixed point to floating point format.
sr	1	1	1	0	1	0	0	CHSS	Change sign of 16-bit fixed point operand on TOS.
sr	0	1	1	0	1	0	0	CHSD	Change sign of 32-bit fixed point operand on TOS.
sr	0	0	1	0	1	0	1	CHSF	Change sign of floating point operand on TOS.
sr	1	1	1	0	1	1	1	PTOS	Push 16-bit fixed point operand on TOS to NOS (Copy)
sr	0	1	1	0	1	1	1	PTOD	Push 32-bit fixed point operand on TOS to NOS. (Copy)
sr	0	0	1	0	1	1	1	PTOF	Push floating point operand on TOS to NOS. (Copy)
sr	1	1	1	1	0	0	0	POPS	Pop 16-bit fixed point operand from TOS. NOS becomes TOS.
sr	0	1	1	1	0	0	0	POPD	Pop 32-bit fixed point operand from TOS. NOS becomes TOS.
sr	0	0	1	1	0	0	0	POPF	Pop floating point operand from TOS. NOS becomes TOS.
sr	1	1	1	1	0	0	1	XCHS	Exchange 16-bit fixed point operands TOS and NOS.
sr	0	1	1	1	0	0	1	XCHD	Exchange 32-bit fixed point operands TOS and NOS.
sr	0	0	1	1	0	0	1	XCHF	Exchange floating point operands TOS and NOS.
sr	0	0	1	1	0	1	0	PUPI	Push floating point constant " π " onto TOS. Previous TOS becomes NOS.

NOTES:

- TOS means Top of Stack. NOS means Next on Stack.
- AMD Application Brief "Algorithm Details for the Am9511A APU" provides detailed descriptions of each command function, including data ranges, accuracies, stack configurations, etc.
- Many commands destroy one stack location (bottom of stack) during development of the result. The derived functions may destroy several stack locations. See Application Brief for details.
- The trigonometric functions handle angles in radians, not degrees.
- No remainder is available for the fixed-point divide functions.
- Results will be undefined for any combination of command coding bits not specified in this table.

COMMAND INITIATION

After properly positioning the required operands on the stack, a command may be issued. The procedure for initiating a command execution is as follows:

1. Enter the appropriate command on the DB0-DB7 lines.
2. Establish HIGH on the $\overline{C/D}$ input.
3. Establish LOW on the \overline{CS} input.
4. Establish LOW on the \overline{WR} input after an appropriate set up time (see timing diagrams).
5. Sometime after the HIGH to LOW level transition of \overline{WR} input, the \overline{PAUSE} output will become LOW. After a delay of TPPWW, it will go HIGH to acknowledge the write operation. The \overline{WR} input can return to HIGH anytime after \overline{PAUSE} goes HIGH. The DB0-DB7, $\overline{C/D}$ and \overline{CS} inputs are allowed to change after the hold time requirements are satisfied (see timing diagram).

An attempt to issue a new command while the current command execution is in progress is allowed. Under these circumstances, the \overline{PAUSE} output will not go HIGH until the current command execution is completed.

OPERAND ENTRY

The Am9511A commands operate on the operands located at the TOS and NOS and results are returned to the stack at NOS and then popped to TOS. The operands required for the Am9511A are one of three formats – single precision fixed-point (2 bytes), double precision fixed-point (4 bytes) or floating-point (4 bytes). The result of an operation has the same format as the operands except for float to fix or fix to float commands.

Operands are always entered into the stack least significant byte first and most significant byte last. The following procedure must be followed to enter operands onto the stack:

1. The lower significant operand byte is established on the DB0-DB7 lines.
2. A LOW is established on the $\overline{C/D}$ input to specify that data is to be entered into the stack.
3. The \overline{CS} input is made LOW.
4. After appropriate set up time (see timing diagrams), the \overline{WR} input is made LOW. The \overline{PAUSE} output will become LOW.
5. Sometime after this event, the \overline{PAUSE} will return HIGH to indicate that the write operation has been acknowledged.
6. Anytime after the \overline{PAUSE} output goes HIGH the \overline{WR} input can be made HIGH. The DB0-DB7, $\overline{C/D}$ and \overline{CS} inputs can change after appropriate hold time requirements are satisfied (see timing diagrams).

The above procedure must be repeated until all bytes of the operand are pushed into the stack. It should be noted that for single precision fixed-point operands 2 bytes should be pushed and 4 bytes must be pushed for double precision fixed-point or floating-point. Not pushing all the bytes of a quantity will result in byte pointer misalignment.

The Am9511A stack can accommodate 8 single precision fixed-point quantities or 4 double precision fixed-point or floating-point quantities. Pushing more quantities than the capacity of the stack will result in loss of data which is usual with any LIFO stack.

DATA REMOVAL

Result from an operation will be available at the TOS. Results can be transferred from the stack to the data bus by reading the stack. When the stack is popped for results, the most significant byte is available first and the least significant byte last. A result is always of the same precision as the operands that produced it

except for format conversion commands. Thus when the result is taken from the stack, the total number of bytes popped out should be appropriate with the precision – single precision results are 2 bytes and double precision and floating-point results are 4 bytes. The following procedure must be used for reading the result from the stack:

1. A LOW is established on the $\overline{C/D}$ input.
2. The \overline{CS} input is made LOW.
3. After appropriate set up time (see timing diagrams), the \overline{RD} input is made LOW. The \overline{PAUSE} will become LOW.
4. Sometime after this, \overline{PAUSE} will return HIGH indicating that the data is available on the DB0-DB7 lines. This data will remain on the DB0-DB7 lines as long as the \overline{RD} input remains LOW.
5. Anytime after \overline{PAUSE} goes HIGH, the \overline{RD} input can return HIGH to complete transaction.
6. The \overline{CS} and $\overline{C/D}$ inputs can change after appropriate hold time requirements are satisfied (see timing diagram).
7. Repeat this procedure until all bytes appropriate for the precision of the result are popped out.

Reading of the stack does not alter its data; it only adjusts the byte pointer. If more data is popped than the capacity of the stack, the internal byte pointer will wrap around and older data will be read again, consistent with the LIFO stack.

STATUS READ

The Am9511A status register can be read without any regard to whether a command is in progress or not. The only implication that has to be considered is the effect this might have on the END output discussed in the signal descriptions.

The following procedure must be followed to accomplish status register reading.

1. Establish HIGH on the $\overline{C/D}$ input.
2. Establish LOW on the \overline{CS} input.
3. After appropriate set up time (see timing diagram) \overline{RD} input is made LOW. The \overline{PAUSE} will become LOW.
4. Sometime after the HIGH to LOW transition of \overline{RD} input, the \overline{PAUSE} will become HIGH indicating that status register contents are available on the DB0-DB7 lines. The status data will remain on DB0-DB7 as long as \overline{RD} input is LOW.
5. The \overline{RD} input can be returned HIGH anytime after \overline{PAUSE} goes HIGH.
6. The $\overline{C/D}$ input and \overline{CS} input can change after satisfying appropriate hold time requirements (see timing diagram).

DATA FORMATS

The Am9511A Arithmetic Processing Unit handles operands in both fixed-point and floating-point formats. Fixed-point operands may be represented in either single (16-bit operands) or double precision (32-bit operands), and are always represented as binary, two's complement values.

16-BIT FIXED-POINT FORMAT

32-BIT FIXED-POINT FORMAT

The sign (positive or negative) of the operand is located in the most significant bit (MSB). Positive values are represented by a sign bit of zero (S = 0). Negative values are represented by the two's complement of the corresponding positive value with a sign bit equal to 1 (S = 1). The range of values that may be accommodated by each of these formats is -32,768 to +32,767 for single precision and -2,147,483,648 to +2,147,483,647 for double precision.

Floating point binary values are represented in a format that permits arithmetic to be performed in a fashion analogous to operations with decimal values expressed in scientific notation.

$$(5.83 \times 10^2)(8.16 \times 10^1) = (4.75728 \times 10^4)$$

In the decimal system, data may be expressed as values between 0 and 10 times 10 raised to a power that effectively shifts the implied decimal point right or left the number of places necessary to express the result in conventional form (e.g., 47,572.8). The value-portion of the data is called the mantissa. The exponent may be either negative or positive.

The concept of floating point notation has both a gain and a loss associated with it. The gain is the ability to represent the significant digits of data with values spanning a large dynamic range limited only by the capacity of the exponent field. For example, in decimal notation if the exponent field is two digits wide, and the mantissa is five digits, a range of values (positive or negative) from 1.0000×10^{-99} to $9.9999 \times 10^{+99}$ can be accommodated. The loss is that only the significant digits of the value can be represented. Thus there is no distinction in this representation between the values 123451 and 123452, for example, since each would be expressed as: 1.2345×10^5 . The sixth digit has been discarded. In most applications where the dynamic range of values to be represented is large, the loss of significance, and hence accuracy of results, is a minor consideration. For greater precision a fixed point format could be chosen, although with a loss of potential dynamic range.

The Am9511 is a binary arithmetic processor and requires that floating point data be represented by a fractional mantissa value between .5 and 1 multiplied by 2 raised to an appropriate power. This is expressed as follows:

$$\text{value} = \text{mantissa} \times 2^{\text{exponent}}$$

For example, the value 100.5 expressed in this form is 0.11001001×2^7 . The decimal equivalent of this value may be computed by summing the components (powers of two) of the mantissa and then multiplying by the exponent as shown below:

$$\begin{aligned} \text{value} &= (2^{-1} + 2^{-2} + 2^{-5} + 2^{-8}) \times 2^7 \\ &= (0.5 + 0.25 + 0.03125 + 0.00290625) \times 128 \\ &= 0.78515625 \times 128 \\ &= 100.5 \end{aligned}$$

FLOATING POINT FORMAT

The format for floating-point values in the Am9511A is given below. The mantissa is expressed as a 24-bit (fractional) value; the exponent is expressed as an unbiased two's complement 7-bit value having a range of -64 to +63. The most significant bit is the sign of the mantissa (0 = positive, 1 = negative), for a total of 32 bits. The binary point is assumed to be to the left of the most significant mantissa bit (bit 23). All floating-point data values must be normalized. Bit 23 must be equal to 1, except for the value zero, which is represented by all zeros.

The range of values that can be represented in this format is $\pm(2.7 \times 10^{-20}$ to $9.2 \times 10^{18})$ and zero.

STATUS REGISTER

The Am9511A contains an eight bit status register with the following bit assignments:

BUSY	SIGN	ZERO	ERROR CODE				CARRY
7	6	5	4	3	2	1	0

- BUSY:** Indicates that Am9511A is currently executing a command (1 = Busy).
- SIGN:** Indicates that the value on the top of stack is negative (1 = Negative).
- ZERO:** Indicates that the value on the top of stack is zero (1 = Value is zero).
- ERROR CODE:** This field contains an indication of the validity of the result of the last operation. The error codes are:
 - 0000 - No error
 - 1000 - Divide by zero
 - 0100 - Square root or log of negative number
 - 1100 - Argument of inverse sine, cosine, or e^x too large
 - XX10 - Underflow
 - XX01 - Overflow
- CARRY:** Previous operation resulted in carry or borrow from most significant bit. (1 = Carry/Borrow, 0 = No Carry/No Borrow)

If the BUSY bit in the status register is a one, the other status bits are not defined; if zero, indicating not busy, the operation is complete and the other status bits are defined as given above.

Table 1.

Command Mnemonic	Hex Code (sr = 1)	Hex Code (sr = 0)	Execution Cycles	Summary Description
16-BIT FIXED-POINT OPERATIONS				
SADD	EC	6C	16-18	Add TOS to NOS. Result to NOS. Pop Stack.
SSUB	ED	6D	30-32	Subtract TOS from NOS. Result to NOS. Pop Stack.
SMUL	EE	6E	84-94	Multiply NOS by TOS. Lower result to NOS. Pop Stack.
SMUU	F6	76	80-98	Multiply NOS by TOS. Upper result to NOS. Pop Stack.
SDIV	EF	6F	84-94	Divide NOS by TOS. Result to NOS. Pop Stack.
32-BIT FIXED-POINT OPERATIONS				
DADD	AC	2C	20-22	Add TOS to NOS. Result to NOS. Pop Stack.
DSUB	AD	2D	38-40	Subtract TOS from NOS. Result to NOS. Pop Stack.
DMUL	AE	2E	194-210	Multiply NOS by TOS. Lower result to NOS. Pop Stack.
DMUU	B6	36	182-218	Multiply NOS by TOS. Upper result to NOS. Pop Stack.
DDIV	AF	2F	196-210	Divide NOS by TOS. Result to NOS. Pop Stack.
32-BIT FLOATING-POINT PRIMARY OPERATIONS				
FADD	90	10	54-368	Add TOS to NOS. Result to NOS. Pop Stack.
FSUB	91	11	70-370	Subtract TOS from NOS. Result to NOS. Pop Stack.
FMUL	92	12	146-168	Multiply NOS by TOS. Result to NOS. Pop Stack.
FDIV	93	13	154-184	Divide NOS by TOS. Result to NOS. Pop Stack.
32-BIT FLOATING-POINT DERIVED OPERATIONS				
SQRT	81	01	782-870	Square Root of TOS. Result to TOS.
SIN	82	02	3796-4808	Sine of TOS. Result to TOS.
COS	83	03	3840-4878	Cosine of TOS. Result to TOS.
TAN	84	04	4894-5886	Tangent of TOS. Result to TOS.
ASIN	85	05	6230-7938	Inverse Sine of TOS. Result to TOS.
ACOS	86	06	6304-8284	Inverse Cosine of TOS. Result to TOS.
ATAN	87	07	4992-6536	Inverse Tangent of TOS. Result to TOS.
LOG	88	08	4474-7132	Common Logarithm of TOS. Result to TOS.
LN	89	09	4298-6956	Natural Logarithm of TOS. Result to TOS.
EXP	8A	0A	3794-4878	e raised to power in TOS. Result to TOS.
PWR	8B	0B	8290-12032	NOS raised to power in TOS. Result to NOS. Pop Stack.
DATA AND STACK MANIPULATION OPERATIONS				
NOP	80	00	4	No Operation. Clear or set SVREQ.
FIXS	9F	1F	90-214	Convert TOS from floating point format to fixed point format.
FIXD	9E	1E	90-336	
FLTS	9D	1D	62-156	
FLTD	9C	1C	56-342	Convert TOS from fixed point format to floating point format.
CHSS	F4	74	22-24	
CHSD	B4	34	26-28	
CHSF	95	15	16-20	Change sign of floating point operand on TOS.
PTOS	F7	77	16	Push stack. Duplicate NOS in TOS.
PTOD	B7	37	20	
PTOF	97	17	20	
POPS	F8	78	10	Pop stack. Old NOS becomes new TOS. Old TOS rotates to bottom.
POPD	B8	38	12	
POPF	98	18	12	
XCHS	F9	79	18	Exchange TOS and NOS.
XCHD	B9	39	26	
XCHF	99	19	26	
PUPI	9A	1A	16	Push floating point constant π onto TOS. Previous TOS becomes NOS.

COMMAND DESCRIPTIONS

This section contains detailed descriptions of the APU commands. They are arranged in alphabetical order by command mnemonic. In the descriptions, TOS means Top Of Stack and NOS means Next On Stack.

All derived functions except Square Root use Chebyshev polynomial approximating algorithms. This approach is used to help minimize the internal microprogram, to minimize the maximum error values and to provide a relatively even distribution of errors over the data range. The basic arithmetic operations are used by the derived functions to compute the various Chebyshev terms. The basic operations may produce error codes in the status register as a result.

Execution times are listed in terms of clock cycles and may be converted into time values by multiplying by the clock period used. For example, an execution time of 44 clock cy-

cles when running at a 3MHz rate translates to 14 microseconds ($44 \times 32\mu\text{s} = 14\mu\text{s}$). Variations in execution cycles reflect the data dependency of the algorithms.

In some operations exponent overflow or underflow may be possible. When this occurs, the exponent returned in the result will be 128 greater or smaller than its true value.

Many of the functions use portions of the data stack as scratch storage during development of the results. Thus previous values in those stack locations will be lost. Scratch locations destroyed are listed in the command descriptions and shown with the crossed-out locations in the Stack Contents After diagram.

Table 1 is a summary of all the Am9511A commands. It shows the hex codes for each command, the mnemonic abbreviation, a brief description and the execution time in clock cycles. The commands are grouped by functional classes.

The command mnemonics in alphabetical order are shown below in Table 2.

Table 2.

Command Mnemonics in Alphabetical Order.

ACOS	ARCCOSINE	LOG	COMMON LOGARITHM
ASIN	ARCSINE	LN	NATURAL LOGARITHM
ATAN	ARCTANGENT	NOP	NO OPERATION
CHSD	CHANGE SIGN DOUBLE	POPD	POP STACK DOUBLE
CHSF	CHANGE SIGN FLOATING	POPF	POP STACK FLOATING
CHSS	CHANGE SIGN SINGLE	POPS	POP STACK SINGLE
COS	COSINE	PTOD	PUSH STACK DOUBLE
DADD	DOUBLE ADD	PTOF	PUSH STACK FLOATING
DDIV	DOUBLE DIVIDE	PTOS	PUSH STACK SINGLE
DMUL	DOUBLE MULTIPLY LOWER	PUPI	PUSH π
DMUU	DOUBLE MULTIPLY UPPER	PWR	POWER (X^Y)
DSUB	DOUBLE SUBTRACT	SADD	SINGLE ADD
EXP	EXPONENTIATION (e^X)	SDIV	SINGLE DIVIDE
FADD	FLOATING ADD	SIN	SINE
FDIV	FLOATING DIVIDE	SMUL	SINGLE MULTIPLY LOWER
FIXD	FIX DOUBLE	SMUU	SINGLE MULTIPLY UPPER
FIXS	FIX SINGLE	SQRT	SQUARE ROOT
FLTD	FLOAT DOUBLE	SSUB	SINGLE SUBTRACT
FLTS	FLOAT SINGLE	TAN	TANGENT
FMUL	FLOATING MULTIPLY	XCHD	EXCHANGE OPERANDS DOUBLE
FSUB	FLOATING SUBTRACT	XCHF	EXCHANGE OPERANDS FLOATING
		XCHS	EXCHANGE OPERANDS SINGLE

ACOS

32-BIT FLOATING-POINT INVERSE COSINE

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	0	0	0	1	1	0

Hex Coding: 86 with sr = 1
06 with sr = 0

Execution Time: 6304 to 8284 clock cycles

Description:

The 32-bit floating-point operand A at the TOS is replaced by the 32-bit floating-point inverse cosine of A. The result R is a value in radians between 0 and π . Initial operands A, B, C and D are lost. ACOS will accept all input data values within the range of -1.0 to $+1.0$. Values outside this range will return an error code of 1100 in the status register.

Accuracy: ACOS exhibits a maximum relative error of 2.0×10^{-7} over the valid input data range.

Status Affected: Sign, Zero, Error Field

STACK CONTENTS

ASIN

32-BIT FLOATING-POINT INVERSE SINE

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	0	0	0	1	0	1

Hex Coding: 85 with sr = 1
05 with sr = 0

Execution Time: 6230 to 7938 clock cycles

Description:

The 32-bit floating-point operand A at the TOS is replaced by the 32-bit floating-point inverse sine of A. The result R is a value in radians between $-\pi/2$ and $+\pi/2$. Initial operands A, B, C and D are lost.

ASIN will accept all input data values within the range of -1.0 to $+1.0$. Values outside this range will return an error code of 1100 in the status register.

Accuracy: ASIN exhibits a maximum relative error of 4.0×10^{-7} over the valid input data range.

Status Affected: Sign, Zero, Error Field

STACK CONTENTS

ATAN

32-BIT FLOATING-POINT INVERSE TANGENT

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	0	0	0	1	1	1

Hex Coding: 87 with sr = 1
07 with sr = 0

Execution Time: 4992 to 6536 clock cycles

Description:

The 32-bit floating-point operand A at the TOS is replaced by the 32-bit floating-point inverse tangent of A. The result R is a value in radians between $-\pi/2$ and $+\pi/2$. Initial operands A, C and D are lost. Operand B is unchanged.

ATAN will accept all input data values that can be represented in the floating point format.

Accuracy: ATAN exhibits a maximum relative error of 3.0×10^{-7} over the input data range.

Status Affected: Sign, Zero

STACK CONTENTS

4

CHSD

32-BIT FIXED-POINT SIGN CHANGE

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	1	1	0	1	0	0

Hex Coding: B4 with sr = 1
34 with sr = 0

Execution Time: 26 to 28 clock cycles

Description:

The 32-bit fixed-point two's complement integer operand A at the TOS is subtracted from zero. The result R replaces A at the TOS. Other entries in the stack are not disturbed.

Overflow status will be set and the TOS will be returned unchanged when A is input as the most negative value possible in the format since no positive equivalent exists.

Status Affected: Sign, Zero, Error Field (overflow)

STACK CONTENTS

CHSF

32-BIT FLOATING-POINT SIGN CHANGE

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	0	1	0	1	0	1

Hex Coding: 95 with sr = 1
15 with sr = 0

Execution Time: 16 to 20 clock cycles

Description:

The sign of the mantissa of the 32-bit floating-point operand A at the TOS is inverted. The result R replaces A at the TOS. Other stack entries are unchanged.

If A is input as zero (mantissa MSB = 0), no change is made.

Status Affected: Sign, Zero

STACK CONTENTS

CHSS

16-BIT FIXED-POINT SIGN CHANGE

Binary Coding:

7	6	5	4	3	2	1	0
sr	1	1	1	0	1	0	0

Hex Coding: F4 with sr = 1
74 with sr = 0

Execution Time: 22 to 24 clock cycles

Description:

16-bit fixed-point two's complement integer operand A at the TOS is subtracted from zero. The result R replaces A at the TOS. All other operands are unchanged.

Overflow status will be set and the TOS will be returned unchanged when A is input as the most negative value possible in the format since no positive equivalent exists.

Status Affected: Sign, Zero, Overflow

STACK CONTENTS

COS

32-BIT FLOATING-POINT COSINE

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	0	0	0	0	1	1

Hex Coding: 83 with sr = 1
03 with sr = 0

Execution Time: 3840 to 4878 clock cycles

Description:

The 32-bit floating-point operand A at the TOS is replaced by R, the 32-bit floating-point cosine of A. A is assumed to be in radians. Operands A, C and D are lost. B is unchanged.

The COS function can accept any input data value that can be represented in the data format. All input values are range reduced to fall within an interval of $-\pi/2$ to $+\pi/2$ radians.

Accuracy: COS exhibits a maximum relative error of 5.0×10^{-7} for all input data values in the range of -2π to $+2\pi$ radians.

Status Affected: Sign, Zero

STACK CONTENTS

DADD

32-BIT FIXED-POINT ADD

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	0	1	1	0	0

Hex Coding: AC with sr = 1
2C with sr = 0

Execution Time: 20 to 22 clock cycles

Description:

The 32-bit fixed-point two's complement integer operand A at the TOS is added to the 32-bit fixed-point two's complement integer operand B at the NOS. The result R replaces operand B and the Stack is moved up so that R occupies the TOS. Operand B is lost. Operands A, C and D are unchanged. If the addition generates a carry it is reported in the status register.

If the result is too large to be represented by the data format, the least significant 32 bits of the result are returned and overflow status is reported.

Status Affected: Sign, Zero, Carry, Error Field

STACK CONTENTS

DDIV

32-BIT FIXED-POINT DIVIDE

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	0	1	1	1	1

Hex Coding: AF with sr = 1
2F with sr = 0

Execution Time: 196 to 210 clock cycles when A ≠ 0
18 clock cycles when A = 0.

Description:

The 32-bit fixed-point two's complement integer operand B at the NOS is divided by the 32-bit fixed-point two's complement integer operand A at the TOS. The 32-bit integer quotient R replaces B and the stack is moved up so that R occupies the TOS. No remainder is generated. Operands A and B are lost. Operands C and D are unchanged.

If A is zero, R is set equal to B and the divide-by-zero error status will be reported. If either A or B is the most negative value possible in the format, R will be meaningless and the overflow error status will be reported.

Status Affected: Sign, Zero, Error Field

DMUL

32-BIT FIXED-POINT MULTIPLY, LOWER

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	0	1	1	1	0

Hex Coding: AE with sr = 1
2E with sr = 0

Execution Time: 194 to 210 clock cycles

Description:

The 32-bit fixed-point two's complement integer operand A at the TOS is multiplied by the 32-bit fixed-point two's complement integer operand B at the NOS. The 32-bit least significant half of the product R replaces B and the stack is moved up so that R occupies the TOS. The most significant half of the product is lost. Operands A and B are lost. Operands C and D are unchanged.

The overflow status bit is set if the discarded upper half was non-zero. If either A or B is the most negative value that can be represented in the format, that value is returned as R and the overflow status is set.

Status Affected: Sign, Zero, Overflow

DMUU

32-BIT FIXED-POINT MULTIPLY, UPPER

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	1	0	1	1	0

Hex Coding: B6 with sr = 1
36 with sr = 0

Execution Time: 182 to 218 clock cycles

Description:

The 32-bit fixed-point two's complement integer operand A at the TOS is multiplied by the 32-bit fixed-point two's complement integer operand B at the NOS. The 32-bit most significant half of the product R replaces B and the stack is moved up so that R occupies the TOS. The least significant half of the product is lost. Operands A and B are lost. Operands C and D are unchanged.

If A or B was the most negative value possible in the format, overflow status is set and R is meaningless.

Status Affected: Sign, Zero, Overflow

4

DSUB

32-BIT FIXED-POINT SUBTRACT

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	0	1	1	0	1

Hex Coding: AD with sr = 1
2D with sr = 0

Execution Time: 38 to 40 clock cycles

Description:

The 32-bit fixed-point two's complement operand A at the TOS is subtracted from the 32-bit fixed-point two's complement operand B at the NOS. The difference R replaces B and the stack is moved up so that R occupies the TOS. Operand B is lost. Operands A, C and D are unchanged.

If the subtraction generates a borrow it is reported in the carry status bit. If A is the most negative value that can be represented in the format the overflow status is set. If the result cannot be represented in the data format range, the overflow bit is set and the 32 least significant bits of the result are returned as R.

Status Affected: Sign, Zero, Carry, Overflow

EXP

32-BIT FLOATING-POINT e^x

Hex Coding: 8A with sr = 1
0A with sr = 0

Execution Time: 3794 to 4878 clock cycles for $|A| \leq 1.0 \times 2^{+5}$
34 clock cycles for $|A| > 1.0 \times 2^{+5}$

Description:

The base of natural logarithms, e, is raised to an exponent value specified by the 32-bit floating-point operand A at the TOS. The result R of e^A replaces A. Operands A, C and D are lost. Operand B is unchanged.

EXP accepts all input data values within the range of $-1.0 \times 2^{+5}$ to $+1.0 \times 2^{+5}$. Input values outside this range will return a code of 1100 in the error field of the status register.

Accuracy: EXP exhibits a maximum relative error of 5.0×10^{-7} over the valid input data range.

Status Affected: Sign, Zero, Error Field

FADD

32-BIT FLOATING-POINT ADD

Hex Coding: 90 with sr = 1
10 with sr = 0

Execution Time: 54 to 368 clock cycles for $A \neq 0$
24 clock cycles for $A = 0$

Description:

32-bit floating-point operand A at the TOS is added to 32-bit floating-point operand B at the NOS. The result R replaces B and the stack is moved up so that R occupies the TOS. Operands A and B are lost. Operands C and D are unchanged.

Exponent alignment before the addition and normalization of the result accounts for the variation in execution time. Exponent overflow and underflow are reported in the status register, in which case the mantissa is correct and the exponent is offset by 128.

Status Affected: Sign, Zero, Error Field

FDIV

32-BIT FLOATING-POINT DIVIDE

Hex Coding: 93 with sr = 1
13 with sr = 0

Execution Time: 154 to 184 clock cycles for $A \neq 0$
22 clock cycles for $A = 0$

Description:

32-bit floating-point operand B at NOS is divided by 32-bit floating-point operand A at the TOS. The result R replaces B and the stack is moved up so that R occupies the TOS. Operands A and B are lost. Operands C and D are unchanged.

If operand A is zero, R is set equal to B and the divide-by-zero error is reported in the status register. Exponent overflow or underflow is reported in the status register, in which case the mantissa portion of the result is correct and the exponent portion is offset by 128.

Status Affected: Sign, Zero, Error Field

FIXD

32-BIT FLOATING-POINT TO 32-BIT FIXED-POINT CONVERSION

Hex Coding: 9E with sr = 1
1E with sr = 0

Execution Time: 90 to 336 clock cycles

Description:

32-bit floating-point operand A at the TOS is converted to a 32-bit fixed-point two's complement integer. The result R replaces A. Operands A and D are lost. Operands B and C are unchanged.

If the integer portion of A is larger than 31 bits when converted, the overflow status will be set and A will not be changed. Operand D, however, will still be lost.

Status Affected: Sign, Zero Overflow

FIXS

32-BIT FLOATING-POINT TO 16-BIT FIXED-POINT CONVERSION

Hex Coding: 9F with sr = 1
1F with sr = 0

Execution Time: 90 to 214 clock cycles

Description:

32-bit floating-point operand A at the TOS is converted to a 16-bit fixed-point two's complement integer. The result R replaces the lower half of A and the stack is moved up by two bytes so that R occupies the TOS. Operands A and D are lost. Operands B and C are unchanged, but appear as upper (u) and lower (l) halves on the 16-bit wide stack if they are 32-bit operands.

If the integer portion of A is larger than 15 bits when converted, the overflow status will be set and A will not be changed. Operand D, however, will still be lost.

Status Affected: Sign, Zero, Overflow

FLTD

32-BIT FIXED-POINT TO 32-BIT FLOATING-POINT CONVERSION

Hex Coding: 9C with sr = 1
1C with sr = 0

Execution Time: 56 to 342 clock cycles

Description:

32-bit fixed-point two's complement integer operand A at the TOS is converted to a 32-bit floating-point number. The result R replaces A at the TOS. Operands A and D are lost. Operands B and C are unchanged.

Status Affected: Sign, Zero

FLTS

16-BIT FIXED-POINT TO 32-BIT FLOATING-POINT CONVERSION

Hex Coding: 9D with sr = 1
1D with sr = 0

Execution Time: 62 to 156 clock cycles

Description:

16-bit fixed-point two's complement integer A at the TOS is converted to a 32-bit floating-point number. The lower half of the result R (Rl) replaces A, the upper half (Ru) replaces H and the stack is moved down so that Ru occupies the TOS. Operands A, F, G and H are lost. Operands B, C, D and E are unchanged.

Status Affected: Sign, Zero

4

FMUL

32-BIT FLOATING-POINT MULTIPLY

Hex Coding: 92 with sr = 1
12 with sr = 0

Execution Time: 146 to 168 clock cycles

Description:

32-bit floating-point operand A at the TOS is multiplied by the 32-bit floating-point operand B at the NOS. The normalized result R replaces B and the stack is moved up so that R occupies the TOS. Operands A and B are lost. Operands C and D are unchanged.

Exponent overflow or underflow is reported in the status register, in which case the mantissa portion of the result is correct and the exponent portion is offset by 128.

Status Affected: Sign, Zero, Error Field

FSUB

32-BIT FLOATING-POINT SUBTRACTION

Hex Coding: 91 with sr = 1
11 with sr = 0

Execution Time: 70 to 370 clock cycles for A ≠ 0
26 clock cycles for A = 0

Description:
32-bit floating-point operand A at the TOS is subtracted from 32-bit floating-point operand B at the NOS. The normalized difference R replaces B and the stack is moved up so that R occupies the TOS. Operands A and B are lost. Operands C and D are unchanged.

Exponent alignment before the subtraction and normalization of the result account for the variation in execution time. Exponent overflow or underflow is reported in the status register in which case the mantissa portion of the result is correct and the exponent portion is offset by 128.

Status Affected: Sign, Zero, Error Field (overflow)

LOG

32-BIT FLOATING-POINT COMMON LOGARITHM

Hex Coding: 88 with sr = 1
08 with sr = 0

Execution Time: 4474 to 7132 clock cycles for A > 0
20 clock cycles for A ≤ 0

Description:
The 32-bit floating-point operand A at the TOS is replaced by R, the 32-bit floating-point common logarithm (base 10) of A. Operands A, C and D are lost. Operand B is unchanged. The LOG function accepts any positive input data value that can be represented by the data format. If LOG of a non-positive value is attempted an error status of 0100 is returned.

Accuracy: LOG exhibits a maximum absolute error of 2.0×10^{-7} for the input range from 0.1 to 10, and a maximum relative error of 2.0×10^{-7} for positive values less than 0.1 or greater than 10.

Status Affected: Sign, Zero, Error Field

LN

32-BIT FLOATING-POINT NATURAL LOGARITHM

Hex Coding: 89 with sr = 1
09 with sr = 0

Execution Time: 4298 to 6956 clock cycles for A > 0
20 clock cycles for A ≤ 0

Description:
The 32-bit floating-point operand A at the TOS is replaced by R, the 32-bit floating-point natural logarithm (base e) of A. Operands A, C and D are lost. Operand B is unchanged. The LN function accepts all positive input data values that can be represented by the data format. If LN of a non-positive number is attempted an error status of 0100 is returned.

Accuracy: LN exhibits a maximum absolute error of 2×10^{-7} for the input range from e^{-1} to e, and a maximum relative error of 2.0×10^{-7} for positive values less than e^{-1} or greater than e.

Status Affected: Sign, Zero, Error Field

NOP

NO OPERATION

Hex Coding: 80 with sr = 1
00 with sr = 0

Execution Time: 4 clock cycles

Description:
The NOP command performs no internal data manipulations. It may be used to set or clear the service request interface line without changing the contents of the stack.

Status Affected: The status byte is cleared to all zeroes.

POPD

32-BIT STACK POP

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	1	1	0	0	0

Hex Coding: B8 with sr = 1
38 with sr = 0

Execution Time: 12 clock cycles

Description:

The 32-bit stack is moved up so that the old NOS becomes the new TOS. The previous TOS rotates to the bottom of the stack. All operand values are unchanged. POPD and POPF execute the same operation.

Status Affected: Sign, Zero

STACK CONTENTS

POPS

16-BIT STACK POP

Binary Coding:

7	6	5	4	3	2	1	0
sr	1	1	1	1	0	0	0

Hex Coding: F8 with sr = 1
78 with sr = 0

Execution Time: 10 clock cycles

Description:

The 16-bit stack is moved up so that the old NOS becomes the new TOS. The previous TOS rotates to the bottom of the stack. All operand values are unchanged.

Status Affected: Sign, Zero

STACK CONTENTS

4

POPF

32-BIT STACK POP

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	0	1	1	0	0	0

Hex Coding: 98 with sr = 1
18 with sr = 0

Execution Time: 12 clock cycles

Description:

The 32-bit stack is moved up so that the old NOS becomes the new TOS. The old TOS rotates to the bottom of the stack. All operand values are unchanged. POPF and POPD execute the same operation.

Status Affected: Sign, Zero

STACK CONTENTS

PTOD

PUSH 32-BIT TOS ONTO STACK

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	1	1	0	1	1	1

Hex Coding: B7 with sr = 1
37 with sr = 0

Execution Time: 20 clock cycles

Description:

The 32-bit stack is moved down and the previous TOS is copied into the new TOS location. Operand D is lost. All other operand values are unchanged. PTOD and PTOF execute the same operation.

Status Affected: Sign, Zero

STACK CONTENTS

PTOF

PUSH 32-BIT
TOS ONTO STACK

7 6 5 4 3 2 1 0

Binary Coding:

sr	0	0	1	0	1	1	1
----	---	---	---	---	---	---	---

Hex Coding: 97 with sr = 1
17 with sr = 0

Execution Time: 20 clock cycles

Description:

The 32-bit stack is moved down and the previous TOS is copied into the new TOS location. Operand D is lost. All other operand values are unchanged. PTOF and PTOD execute the same operation.

Status Affected: Sign, Zero

STACK CONTENTS

PUPI

PUSH 32-BIT

Hex Coding: F7 with sr = 1
77 with sr = 0

Execution Time: 16 clock cycles

Description:

The 16-bit stack is moved down and the previous TOS is copied into the new TOS location. Operand H is lost and all other operand values are unchanged.

Status Affected: Sign, Zero

STACK CONTENTS

PWR

32-BIT
FLOATING-POINT X^Y

7 6 5 4 3 2 1 0

Binary Coding:

sr	0	0	0	1	0	1	1
----	---	---	---	---	---	---	---

Hex Coding: 8B with sr = 1
0B with sr = 0

Execution Time: 8290 to 12032 clock cycles

Description:

32-bit floating-point operand B at the NOS is raised to the power specified by the 32-bit floating-point operand A at the TOS. The result R of B^A replaces B and the stack is moved up so that R occupies the TOS. Operands A, B, and D are lost. Operand C is unchanged.

The PWR function accepts all input data values that can be represented in the data format for operand A and all positive values for operand B. If operand B is non-positive an error status of 0100 will be returned. The EXP and LN functions are used to implement PWR using the relationship B^A = EXP [A(LN B)]. Thus if the term [A(LN B)] is outside the range of -1.0 x 2⁺⁵ to +1.0 x 2⁺⁵ an error status of 1100 will be returned. Underflow and overflow conditions can occur.

Accuracy: The error performance for PWR is a function of the LN and EXP performance as expressed by:

$$|(Relative\ Error)_{PWR}| = |(Relative\ Error)_{EXP} + |A(Absolute\ Error)_{LN}|$$

The maximum relative error for PWR occurs when A is at its maximum value while [A(LN B)] is near 1.0 x 2⁵ and the EXP error is also at its maximum. For most practical applications the relative error for PWR will be less than 7.0 x 10⁻⁷

Status Affected: Sign, Zero, Error Field

SADD

16-BIT
FIXED-POINT ADD

7 6 5 4 3 2 1 0

Binary Coding:

sr	1	1	0	1	1	0	0
----	---	---	---	---	---	---	---

Hex Coding: EC with sr = 1
6C with sr = 0

Execution Time: 16 to 18 clock cycles

Description:

16-bit fixed-point two's complement integer operand A at the TOS is added to 16-bit fixed-point two's complement integer operand D at the NOS. The result R replaces B and the stack is moved up so that R occupies the TOS. Operand B is lost. All other operands are unchanged.

If the addition generates a carry bit it is reported in the status register. If an overflow occurs it is reported in the status register and the 16 least significant bits of the result are returned.

Status Affected: Sign, Zero, Carry, Error Field

SDIV

16-BIT
FIXED-POINT DIVIDE

Binary Coding:

7	6	5	4	3	2	1	0
sr	1	1	0	1	1	1	1

Hex Coding: EF with sr = 1
6F with sr = 0

Execution Time: 84 to 94 clock cycles for A ≠ 0
14 clock cycles for A = 0

Description:

16-bit fixed-point two's complement integer operand B at the NOS is divided by 16-bit fixed-point two's complement integer operand A at the TOS. The 16-bit integer quotient R replaces B and the stack is moved up so that R occupies the TOS. No remainder is generated. Operands A and B are lost. All other operands are unchanged.

If A is zero, R will be set equal to B and the divide-by-zero error status will be reported.

Status Affected: Sign, Zero, Error Field

SIN

32-BIT
FLOATING-POINT SINE

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	0	0	0	0	1	0

Hex Coding: 82 with sr = 1
02 with sr = 0

Execution Time: 3796 to 4808 clock cycles for |A| > 2⁻¹² radians
30 clock cycles for |A| ≤ 2⁻¹² radians

Description:

The 32-bit floating-point operand A at the TOS is replaced by R, the 32-bit floating-point sine of A. A is assumed to be in radians. Operands A, C and D are lost. Operand B is unchanged.

The SIN function will accept any input data value that can be represented by the data format. All input values are range reduced to fall within the interval -π/2 to +π/2 radians.

Accuracy: SIN exhibits a maximum relative error of 5.0 x 10⁻⁷ for input values in the range of -2π to +2π radians.

Status Affected: Sign, Zero

SMUL

16-BIT FIXED-POINT
MULTIPLY, LOWER

7	6	5	4	3	2	1	0
sr	1	1	0	1	1	1	0

Binary Coding:

Hex Coding: EE with sr = 1

6E with sr = 0

Execution Time: 84 to 94 clock cycles

Description:

16-bit fixed-point two's complement integer operand A at the TOS is multiplied by the 16-bit fixed-point two's complement integer operand B at the NOS. The 16-bit least significant half of the product R replaces B and the stack is moved up so that R occupies the TOS. The most significant half of the product is lost. Operands A and B are lost. All other operands are unchanged. The overflow status bit is set if the discarded upper half was non-zero. If either A or B is the most negative value that can be represented in the format, that value is returned as R and the overflow status is set.

Status Affected: Sign, Zero, Error Field

SMUU

16-BIT FIXED-POINT
MULTIPLY, UPPER

7	6	5	4	3	2	1	0
sr	1	1	1	0	1	1	0

Binary Coding:

Hex Coding: F6 with sr = 1

76 with sr = 0

Execution Time: 80 to 98 clock cycles

Description:

16-bit fixed-point two's complement integer operand A at the TOS is multiplied by the 16-bit fixed-point two's complement integer operand B at the NOS. The 16-bit most significant half of the product R replaces B and the stack is moved up so that R occupies the TOS. The least significant half of the product is lost. Operands A and B are lost. All other operands are unchanged.

If either A or B is the most negative value that can be represented in the format, that value is returned as R and the overflow status is set.

Status Affected: Sign, Zero, Error Field

SQRT

32-BIT FLOATING-POINT SQUARE ROOT

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	0	0	0	0	0	1

Hex Coding: 81 with sr = 1
01 with sr = 0

Execution Time: 782 to 870 clock cycles

Description:

32-bit floating-point operand A at the TOS is replaced by R, the 32-bit floating-point square root of A. Operands A and D are lost. Operands B and C are not changed.

SQRT will accept any non-negative input data value that can be represented by the data format. If A is negative an error code of 0100 will be returned in the status register.

Status Affected: Sign, Zero, Error Field

SSUB

16-BIT FIXED-POINT SUBTRACT

	7	6	5	4	3	2	1	0
Binary Coding:	sr	1	1	0	1	1	0	1

Hex Coding: ED with sr = 1
6D with sr = 0

Execution Time: 30 to 32 clock cycles

Description:

16-bit fixed-point two's complement integer operand A at the TOS is subtracted from 16-bit fixed-point two's complement integer operand B at the NOS. The result R replaces B and the stack is moved up so that R occupies the TOS. Operand B is lost. All other operands are unchanged.

If the subtraction generates a borrow it is reported in the carry status bit. If A is the most negative value that can be represented in the format the overflow status is set. If the result cannot be represented in the format range, the overflow status is set and the 16 least significant bits of the result are returned as R.

Status Affected: Sign, Zero, Carry, Error Field

TAN

32-BIT FLOATING-POINT TANGENT

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	0	0	0	1	0	0

Hex Coding: 84 with sr = 1
04 with sr = 0

Execution Time: 4894 to 5886 clock cycles for $|A| \geq 2^{-12}$ radians
30 clock cycles for $|A| \leq 2^{-12}$ radians

Description:

The 32-bit floating-point operand A at the TOS is replaced by the 32-bit floating-point tangent of A. Operand A is assumed to be in radians. A, C and D are lost. B is unchanged.

The TAN function will accept any input data value that can be represented in the data format. All input data values are range-reduced to fall within $-\pi/4$ to $+\pi/4$ radians. TAN is unbounded for input values near odd multiples of $\pi/2$ and in such cases the overflow bit is set in the status register. For angles smaller than 2^{-12} radians, TAN returns A as the tangent of A.

Accuracy: TAN exhibits a maximum relative error of 5.0×10^{-7} for input data values in the range of -2π to $+2\pi$ radians except for data values near odd multiples of $\pi/2$.

Status Affected: Sign, Zero, Error Field (overflow)

XCHD

EXCHANGE 32-BIT STACK OPERANDS

	7	6	5	4	3	2	1	0
Binary Coding:	sr	0	1	1	1	0	0	1

Hex Coding: B9 with sr = 1
39 with sr = 0

Execution Time: 26 clock cycles

Description:

32-bit operand A at the TOS and 32-bit operand B at the NOS are exchanged. After execution, B is at the TOS and A is at the NOS. All operands are unchanged. XCHD and XCHF execute the same operation.

Status Affected: Sign, Zero

XCHF

EXCHANGE 32-BIT
STACK OPERANDS

Binary Coding:

7	6	5	4	3	2	1	0
sr	0	0	1	1	0	0	1

Hex Coding: 99 with sr = 1
19 with sr = 0

Execution Time: 26 clock cycles

Description:

32-bit operand A at the TOS and 32-bit operand B at the NOS are exchanged. After execution, B is at the TOS and A is at the NOS. All operands are unchanged. XCHD and XCHF execute the same operation.

Status Affected: Sign, Zero

XCHS

EXCHANGE 16-BIT
STACK OPERANDS

Binary Coding:

7	6	5	4	3	2	1	0
sr	1	1	1	1	0	0	1

Hex Coding: F9 with sr = 1
79 with sr = 0

Execution Time: 18 clock cycles

Description:

16-bit operand A at the TOS and 16-bit operand B at the NOS are exchanged. After execution, B is at the TOS and A is at the NOS. All operand values are unchanged.

Status Affected: Sign, Zero

Am9511A

MAXIMUM RATINGS beyond which useful life may be impaired

Storage Temperature	-65°C to +150°C
Ambient Temperature Under Bias	-55°C to +125°C
VDD with Respect to VSS	-0.5V to +15.0V
VCC with Respect to VSS	-0.5V to +7.0V
All Signal Voltages with Respect to VSS	-0.5V to +7.0V
Power Dissipation (Package Limitation)	2.0W

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulations of static charge. It is suggested, nevertheless, that conventional precautions be observed during storage, handling and use in order to avoid exposure to excessive voltages.

OPERATING RANGE

Part Number	Ambient Temperature	VSS	VCC	VDD

NOTES

- Typical values are for $T_A = 25^\circ\text{C}$, nominal supply voltages and nominal processing parameters.
- Switching parameters are listed in alphabetical order.
- Test conditions assume transition times of 20ns or less, output loading of one TTL gate plus 100pF and timing reference levels of 0.8V and 2.0V.
- \overline{END} low pulse width is specified for \overline{EACK} tied to VSS. Otherwise TEAE applies.
- Minimum values shown assume no previously entered command is being executed for the data access. If a previously entered command is being executed, \overline{PAUSE} LOW Pulse Width is the time to complete execution plus the time shown.
- \overline{PAUSE} is pulled low for both command and data operations.
- TEX is the execution time of the current command (see the Command Execution Times table).
- \overline{PAUSE} low pulse width is less than 50ns when writing into the data port or the control port as long as the duty cycle requirement (TWI) is observed and no previous command is being executed. TWI may be safely violated as long as the extended TPPWW that results is observed. If a previously entered command is being executed, \overline{PAUSE} LOW Pulse Width is the time to complete execution plus the time shown.
- 150ns for Am9511A-1DM.

APPLICATION INFORMATION

The diagram in Figure 2 shows the interface connections for the Am9511A APU with operand transfers handled by an Am9517 DMA controller, and CPU coordination handled by an Am9519 Interrupt Controller. The APU interrupts the CPU to indicate that a command has been completed. When the performance enhancements provided by the DMA and Interrupt

operations are not required, the APU interface can be simplified as shown in Figure 1. The Am9511A APU is designed with a general purpose 8-bit data bus and interface control so that it can be conveniently used with any general 8-bit processor.

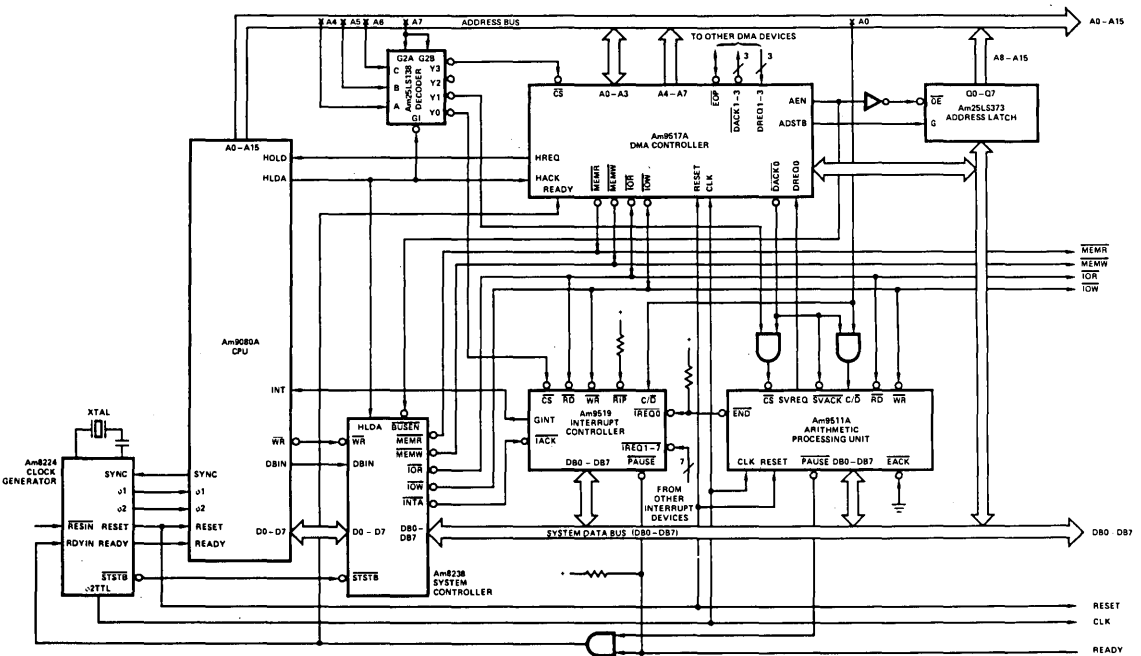

Figure 2. Am9511A High Performance Configuration Example.

MOS-051

Am9512

Floating Point Processor

DISTINCTIVE CHARACTERISTICS

- Single (32-bit) and double (64-bit) precision capability
- Add, subtract, multiply and divide functions
- Compatible with proposed IEEE format
- Easy interfacing to most microprocessors
- 8-bit data bus
- Standard 24-pin package
- 12V and 5V power supplies
- Stack oriented operand storage
- Direct memory access or programmed I/O Data Transfers
- End of execution signal
- Error interrupt

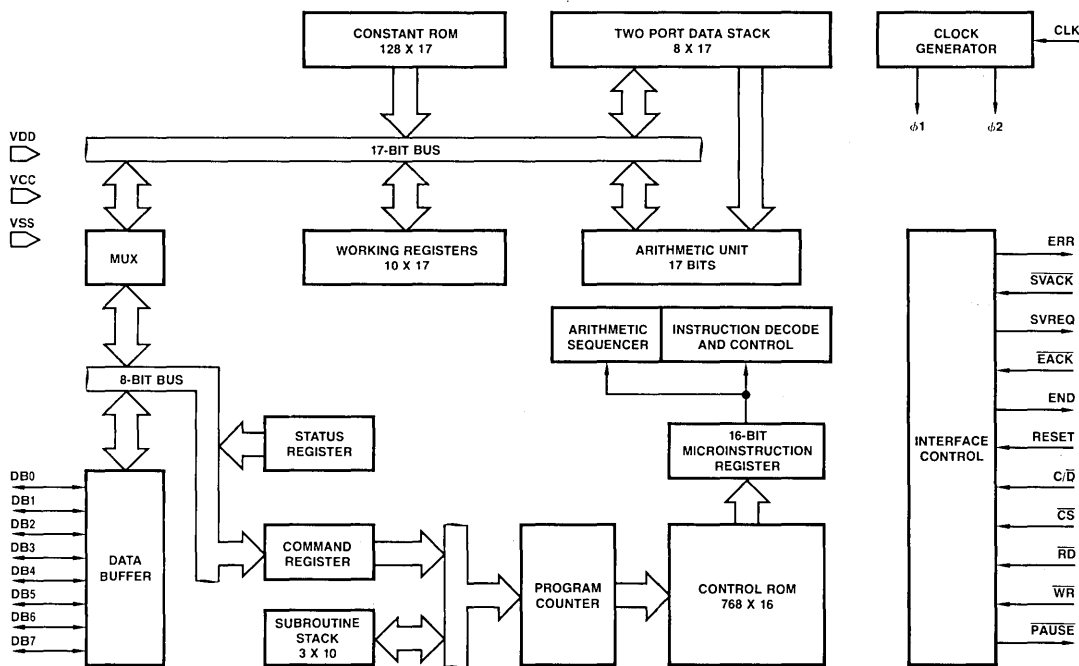

GENERAL DESCRIPTION

The Am9512 is a high performance floating-point processor unit (FPU). It provides single precision (32-bit) and double precision (64-bit) add, subtract, multiply and divide operations. It can be easily interfaced to enhance the computational capabilities of the host microprocessor.

The operand, result, status and command information transfers take place over an 8-bit bidirectional data bus. Operands are pushed onto an internal stack by the host processor and a command is issued to perform an operation on the data stack. The results of this operation are available to the host processor by popping the stack.

Information transfers between the Am9512 and the host processor can be handled by using programmed I/O or direct memory access techniques. After completing an operation, the Am9512 activates an "end of execution" signal that can be used to interrupt the host processor.

MOS-204

INTERFACE SIGNAL DESCRIPTION

VCC: +5V Power Supply

VDD: +12V Power Supply

VSS: Ground

CLK (Clock, Input)

An external timing source connected to the CLK input provides the necessary clocking.

RESET (Reset, Input)

A HIGH on this input causes initialization. Reset terminates any operation in progress, and clears the status register to zero. The internal stack pointer is initialized and the contents of the stack may be affected. After a reset the END output, the ERR output and the SVREQ output will be LOW. For proper initialization, RESET must be HIGH for at least five CLK periods following stable power supply voltages and stable clock.

C/D (Command/Data Select, Input)

The C/D input together with the RD and WR inputs determines the type of transfer to be performed on the data bus as follows:

C/D	RD	WR	Function
L	H	L	Push data byte into the stack
L	L	H	Pop data byte from the stack
H	H	L	Enter command
H	L	H	Read Status
X	L	L	Undefined

L = LOW

H = HIGH

X = DONT CARE

END (End of Execution, Output)

A HIGH on this output indicates that execution of the current command is complete. This output will be cleared LOW by activating the EACK input LOW or performing any read or write operation or device initialization using the RESET. If EACK is tied LOW, the END output will be a pulse (see EACK description).

Reading the status register while a command execution is in progress is allowed. However any read or write operation clears

the flip-flop that generates the END output. Thus such continuous reading could conflict with internal logic setting of the END flip-flop at the end of command execution.

EACK (End Acknowledge, Input)

This input when LOW makes the END output go LOW. As mentioned earlier HIGH on the END output signals completion of a command execution. The END signal is derived from an internal flip-flop which is clocked at the completion of a command. This flip-flop is clocked to the reset state when EACK is LOW. Consequently, if EACK is tied LOW, the END output will be a pulse that is approximately one CLK period wide.

SVREQ (Service Request, Output)

A HIGH on this output indicates completion of a command. In this sense this output is the same as the END output. However, the SVREQ output will go HIGH at the completion of a command. This bit must be 1 for SVREQ to go HIGH. The SVREQ can be cleared (i.e., go LOW) by activating the SVACK input LOW or initializing the device using the RESET. Also, the SVREQ will be automatically cleared after completion of any command that has the service request bit as 0.

SVACK (Service Acknowledge, Input)

A LOW on this input clears SVREQ. If the SVACK input is permanently tied LOW, it will conflict with the internal setting of the SVREQ output. Thus the SVREQ indication cannot be relied upon if the SVACK is tied LOW.

DB0-DB7 (Data Bus, Input/Output)

These eight bidirectional lines are used to transfer command, status and operand information between the device and the host processor. DB0 is the least significant and DB7 is the most significant bit position. HIGH on a data bus line corresponds to 1 and LOW corresponds to 0.

When pushing operands on the stack using the data bus, the least significant byte must be pushed first and most significant byte last. When popping the stack to read the result of an operation, the most significant byte will be available on the data bus first and the least significant byte will be the last. Moreover, for pushing operands and popping results, the number of transactions must be equal to the proper number of bytes appropriate for the chosen format. Otherwise, the internal byte pointer will not be aligned properly. The Am9512 single precision format requires 4 bytes and double precision format requires 8 bytes.

ERR (Error, Output)

This output goes HIGH to indicate that the current command execution resulted in an error condition. The error conditions are: attempt to divide by zero, exponent overflow and exponent underflow. The ERR output is cleared LOW on read status register operation or upon RESET.

The ERR output is derived from the error bits in the status register. These error bits will be updated internally at an appropriate time during a command execution. Thus ERR output going HIGH may not correspond with the completion of a command. Reading of the status register can be performed while a command execution is in progress. However it should be noted that reading the status register clears the ERR output. Thus reading the status register while a command execution in progress may result in an internal conflict with the ERR output.

\overline{CS} (Chip Select, Input)

This input must be LOW to accomplish any read or write operation to the Am9512.

To perform a write operation, appropriate data is presented on DB0 through DB7 lines, appropriate logic level on the C/\overline{D} input and the \overline{CS} input is made LOW. Whenever \overline{WR} and \overline{RD} inputs are both HIGH and \overline{CS} is LOW, \overline{PAUSE} goes LOW. However actual writing into the Am9512 cannot start until \overline{WR} is made LOW. After initiating the write operation by the HIGH to LOW transition on the \overline{WR} input, the \overline{PAUSE} output will go HIGH indicating the write operation has been acknowledged. The \overline{WR} input can go HIGH after \overline{PAUSE} goes HIGH. The data lines, C/\overline{D} input and the \overline{CS} input can change when appropriate hold time requirements are satisfied. See write timing diagram for details.

To perform a read operation an appropriate logic level is established on the C/\overline{D} input and \overline{CS} is made LOW. The \overline{PAUSE} output goes LOW because \overline{WR} and \overline{RD} inputs are HIGH. The read operation does not start until the \overline{RD} input goes LOW. \overline{PAUSE} will go HIGH indicating that read operation is complete and the required information is available on the DB0 through DB7 lines. This information will remain on the data lines as long as \overline{RD} is LOW. The \overline{RD} input can return HIGH anytime after \overline{PAUSE} goes HIGH. The \overline{CS} input and C/\overline{D} input can change anytime after \overline{RD} returns HIGH. See read timing diagram for details. If the \overline{CS} is tied LOW permanently, \overline{PAUSE} will remain LOW until the next Am9512 read or write access.

 \overline{RD} (Read, Input)

A LOW on this input is used to read information from an internal location and gate that information onto the data bus. The \overline{CS} input must be LOW to accomplish the read operation. The C/\overline{D} input determines what internal location is of interest. See C/\overline{D} , \overline{CS} input descriptions and read timing diagram for details. If the END

output was HIGH, performing any read operation will make the END output go LOW after the HIGH to LOW transition of the \overline{RD} input (assuming \overline{CS} is LOW). If the ERR output was HIGH performing a status register read operation will make the ERR output LOW. This will happen after the HIGH to LOW transition of the \overline{RD} input (assuming \overline{CS} is LOW).

 \overline{WR} (Write, Input)

A LOW on this input is used to transfer information from the data bus into an internal location. The \overline{CS} must be LOW to accomplish the write operation. The C/\overline{D} determines which internal location is to be written. See C/\overline{D} , \overline{CS} input descriptions and write timing diagram for details.

If the END output was HIGH, performing any write operation will make the END output go LOW after the LOW to HIGH transition of the \overline{WR} input (assuming \overline{CS} is LOW).

 \overline{PAUSE} (Pause, Output)

This output is a handshake signal used while performing read or write transactions with the Am9512. If the \overline{WR} and \overline{RD} inputs are both HIGH, the \overline{PAUSE} output goes LOW with the \overline{CS} input in anticipation of a transaction. If \overline{WR} goes LOW to initiate a write transaction with proper signals established on the DB0-DB7, C/\overline{D} inputs, the \overline{PAUSE} will return HIGH indicating that the write operation has been accomplished. The \overline{WR} can be made HIGH after this event. On the other hand, if a read operation is desired, the \overline{RD} input is made LOW after activating \overline{CS} LOW and establishing proper C/\overline{D} input. (The \overline{PAUSE} will go LOW in response to \overline{CS} going LOW.) The \overline{PAUSE} will return HIGH indicating completion of read. The \overline{RD} can return HIGH after this event. It should be noted that a read or write operation can be initiated without any regard to whether a command execution is in progress or not. Proper device operation is assured by obeying the \overline{PAUSE} output indication as described.

FUNCTIONAL DESCRIPTION

Major functional units of the Am9512 are shown in the block diagram. The Am9512 employs a microprogram controlled stack oriented architecture with 17-bit wide data paths.

The Arithmetic Unit receives one of its operands from the Operand Stack. This stack is an eight word by 17-bit two port memory with last in – first out (LIFO) attributes. The second operand to the Arithmetic Unit is supplied by the internal 17-bit bus. In addition to supplying the second operand, this bidirectional bus also carries the results from the output of the Arithmetic Unit when required. Writing into the Operand Stack takes place from this internal 17-bit bus when required. Also connected to this bus are the Constant ROM and Working Registers. The ROM provides the required constants to perform the mathematical operations while the Working Registers provide storage for the intermediate values during command execution.

Communication between the external world and the Am9512 takes place on eight bidirectional input/output lines, DB0 through

DB7 (Data Bus). These signals are gated to the internal 8-bit bus through appropriate interface and buffer circuitry. Multiplexing facilities exist for bidirectional communication between the internal eight and 17-bit buses. The Status Register and Command Register are also located on the 8-bit bus.

The Am9512 operations are controlled by the microprogram contained in the Control ROM. The Program Counter supplies the microprogram addresses and can be partially loaded from the Command Register. Associated with the Program Counter is the Subroutine Stack where return addresses are held during subroutine calls in the microprogram. The Microinstruction Register holds the current microinstruction being executed. The register facilitates pipelined microprogram execution. The Instruction Decode logic generates various internal control signals needed for the Am9512 operation.

The Interface Control logic receives several external inputs and provides handshake related outputs to facilitate interfacing the Am9512 to microprocessors.

COMMAND FORMAT

The Operation of the Am9512 is controlled from the host processor by issuing instructions called commands. The command format is shown below:

The command consists of 8 bits; the least significant 7 bits specify the operation to be performed as detailed in the accompanying table. The most significant bit is the Service Request Enable bit. This bit must be a 1 if SVREQ is to go high at end of executing a command.

The Am9512 commands fall into three categories: Single precision arithmetic, double precision arithmetic and data manipulation. There are four arithmetic operations that can be performed with single precision (32-bit), or double precision (64-bit)

floating-point numbers: add, subtract, multiply and divide. These operations require two operands. The Am9512 assumes that these operands are located in the internal stack as Top of Stack (TOS) and Next on Stack (NOS). The result will always be returned to the previous NOS which becomes the new TOS. Results from an operation are of the same precision and format as the operands. The results will be rounded to preserve the accuracy. The actual data formats and rounding procedures are described in a later section. In addition to the arithmetic operations, the Am9512 implements eight data manipulating operations. These include changing the sign of a double or single precision operand located in TOS, exchanging single precision operands located at TOS and NOS, as well as copying and popping single or double precision operands. See also the sections on status register and operand formats.

The Execution times of the Am9512 commands are all data dependent. Table 2 shows one example of each command execution time:

Table 1. Command Decoding Table.

Command Bits								Mnemonic	Description
7	6	5	4	3	2	1	0		
X	0	0	0	0	0	0	1	SADD	Add TOS to NOS Single Precision and result to NOS. Pop stack.
X	0	0	0	0	0	0	0	SSUB	Subtract TOS from NOS Single Precision and result to NOS. Pop stack.
X	0	0	0	0	0	0	1	SMUL	Multiply NOS by TOS Single Precision and result to NOS. Pop stack.
X	0	0	0	0	1	0	0	SDIV	Divide NOS by TOS Single Precision and result to NOS. Pop stack.
X	0	0	0	0	1	0	1	CHSS	Change sign of TOS Single Precision operand.
X	0	0	0	0	1	1	0	PTOS	Push Single Precision operand on TOS to NOS.
X	0	0	0	0	1	1	1	POPS	Pop Single Precision operand from TOS. NOS becomes TOS.
X	0	0	0	1	0	0	0	XCHS	Exchange TOS with NOS Single Precision.
X	0	1	0	1	1	0	1	CHSD	Change sign of TOS Double Precision operand.
X	0	1	0	1	1	1	0	PTOD	Push Double Precision operand on TOS to NOS.
X	0	1	0	1	1	1	1	POPD	Pop Double Precision operand from TOS. NOS becomes TOS.
X	0	0	0	0	0	0	0	CLR	CLR status.
X	0	1	0	1	0	0	1	DADD	Add TOS to NOS Double Precision and result to NOS. Pop stack.
X	0	1	0	1	0	1	0	DSUB	Subtract TOS from NOS Double Precision and result to NOS. Pop stack.
X	0	1	0	1	0	1	1	DMUL	Multiply NOS by TOS Double Precision and result to NOS. Pop stack.
X	0	1	0	1	1	0	0	DDIV	Divide NOS by TOS Double Precision and result to NOS. Pop Stack.

Notes: X = Don't Care

Operation for bit combinations not listed above is undefined.

Table 2. Execution Times.

Command	TOS	NOS	Result	Clock periods
SADD	3F800000	3F800000	40000000	58
SSUB	3F800000	3F800000	00000000	56
SMUL	40400000	3FC00000	40900000	198
SDIV	3F800000	40000000	3F000000	228
CHSS	3F800000	-	BF800000	10
PTOS	3F800000	-	-	16
POPS	3F800000	-	-	14
XCHS	3F800000	40000000	-	26
CHSD	3FF0000000000000	-	BFF0000000000000	24
PTOD	3FF0000000000000	-	-	40
POPD	3FF0000000000000	-	-	26
CLR	3FF0000000000000	-	-	4
DADD	3FF00000A0000000	8000000000000000	3FF00000A0000000	578
DSUB	3FF00000A0000000	8000000000000000	3FF00000A0000000	578
DMUL	BFF8000000000000	3FF8000000000000	C002000000000000	1748
DDIV	BFF8000000000000	3FF8000000000000	BFF0000000000000	4560

Note: TOS, NOS and Result are in hexadecimal; Clock period is in decimal.

COMMAND INITIATION

After properly positioning the required operands in the stack, a command may be issued. The procedure for initiating a command execution is as follows:

1. Establish appropriate command on the DB0-DB7 lines.
2. Establish HIGH on the C/D input.
3. Establish LOW on the CS input. Whenever WR and RD inputs are HIGH the PAUSE output follows the CS input. Hence PAUSE will become LOW.
4. Establish LOW on the WR input after an appropriate set up time (see timing diagrams).
5. Sometime after the HIGH to LOW level transition of WR input, the PAUSE output will become HIGH to acknowledge the write operation. The WR input can return to HIGH anytime after PAUSE goes HIGH. The DB0-DB7, C/D and CS inputs are allowed to change after the hold time requirements are satisfied (see timing diagram).

An attempt to issue a new command while the current command execution is in progress is allowed. Under these circumstances, the PAUSE output will not go HIGH until the current command execution is completed.

OPERAND ENTRY

The Am9512 commands operate on the operands located at the TOS and NOS and results are returned to the stack at NOS and then popped to TOS. The operands required for the Am9512 are one of two formats – single precision floating-point (4 bytes) or double precision floating-point (8 bytes). The result of an operation has the same format as the operands. In other words, operations using single precision quantities always result in a single precision result while operations involving double precision quantities will result in double precision result.

Operands are always entered into the stack least significant byte first and most significant byte last. The following procedure must be followed to enter operands into the stack:

1. The lower significant operand byte is established on the DB0-DB7 lines.
2. A LOW is established on the C/D input to specify that data is to be entered into the stack.
3. The CS input is made LOW. Whenever the WR and RD inputs are HIGH, the PAUSE output will follow the CS input. Thus PAUSE output will become LOW.
4. After appropriate set up time (see timing diagrams), the WR input is made LOW.
5. Sometime after this event, PAUSE will return HIGH to indicate that the write operation has been acknowledged.
6. Anytime after the PAUSE output goes HIGH the WR input can be made HIGH. The DB0-DB7, C/D and CS inputs can change after appropriate hold time requirements are satisfied (see timing diagrams).

The above procedure must be repeated until all bytes of the operand are pushed into the stack. It should be noted that for single precision operands 4 bytes should be pushed and 8 bytes must be pushed for double precision. Not pushing all the bytes of a quantity will result in byte pointer misalignment.

The Am9512 stack can accommodate 4 single precision quantities or 2 double precision quantities. Pushing more quantities than the capacity of the stack will result in loss of data which is usual with any LIFO stack.

REMOVING THE RESULTS

Result from an operation will be available at the TOS. Results can be transferred from the stack to the data bus by reading the stack.

When the stack is popped for results, the most significant byte is available first and the least significant byte last. A result is always of the same precision as the operands that produced it. Thus when the result is taken from the stack, the total number of bytes popped out should be appropriate with the precision – single precision results are 4 bytes and double precision results are 8 bytes. The following procedure must be used for reading the result from the stack:

1. A LOW is established on the C/D input.
2. The CS input is made LOW. When WR and RD inputs are both HIGH, the PAUSE output follows the CS input, thus PAUSE will be LOW.
3. After appropriate set up time (see timing diagrams), the RD input is made LOW.
4. Sometime after this, PAUSE will return HIGH indicating that the data is available on the DB0-DB7 lines. This data will remain on the DB0-DB7 lines as long as the RD input remains LOW.
5. Anytime after PAUSE goes HIGH, the RD input can return HIGH to complete transaction.
6. The CS and C/D inputs can change after appropriate hold time requirements are satisfied (see timing diagram).
7. Repeat this procedure until all bytes appropriate for the precision of the result are popped out.

Reading of the stack does not alter its data; it only adjusts the byte pointer. If more data is popped than the capacity of the stack, the internal byte pointer will wrap around and older data will be read again, consistent with the LIFO stack.

READING STATUS REGISTER

The Am9512 status register can be read without any regard to whether a command is in progress or not. The only implication that has to be considered is the effect this might have on the END and ERR outputs discussed in the signal descriptions.

The following procedure must be followed to accomplish status register reading.

1. Establish HIGH on the C/D input.
2. Establish LOW on the CS input. Whenever WR and RD inputs are HIGH, PAUSE will follow the CS input. Thus, PAUSE will go LOW.
3. After appropriate set up time (see timing diagram) RD is made LOW.
4. Sometime after the HIGH to LOW transition of RD, PAUSE will become HIGH indicating that status register contents are available on the DB0-DB7 lines. These lines will contain this information as long as RD is LOW.
5. The RD input can be returned HIGH anytime after PAUSE goes HIGH.
6. The C/D input and CS input can change after satisfying appropriate hold time requirements (see timing diagram).

DATA FORMATS

The Am9512 handles floating-point quantities in two different formats – single precision and double precision. The single precision quantities are 32-bits long as shown below.

Bit 31:

S = Sign of the mantissa. 1 represents negative and 0 represents positive.

Bits 23-30

E = These 8-bits represent a biased exponent. The bias is $2^7 - 1 = 127$

Bits 0-22

M = 23-bit mantissa. Together with the sign bit, the mantissa represents a signed fraction in sign-magnitude notation. There is an implied 1 beyond the most significant bit (bit 22) of the mantissa. In other words, the mantissa is assumed to be a 24-bit normalized quantity and the most significant bit which will always be 1 due to normalization is implied. The Am9512 restores this implied bit internally before performing arithmetic; normalizes the result and strips the implied bit before returning the results to the external data bus. The binary point is between the implied bit and bit 22 of the mantissa.

The quantity N represented by the above notation is

$$N = (-1)^S 2^{E-(2^7-1)} (1.M)$$

Provided $E \neq 0$ or all 1's.

A double precision quantity consists of the mantissa sign bit(s), an 11 bit biased exponent (E), and a 52-bit mantissa (M). The bias for double precision quantities is $2^{10} - 1$. The double precision format is illustrated below.

**Bit 63:**

S = Sign of the mantissa. 1 represents negative and 0 represents positive.

Bits 52-62

E = These 11 bits represent a biased exponent. The bias is $2^{10} - 1 = 1023$.

Bit 0-51

M = 52-bit mantissa. Together with the sign bit, the mantissa represents a signed fraction in sign-magnitude notation. There is an implied 1 beyond the most significant bit (bit 51) of the mantissa. In other words, the mantissa is assumed to be a 53-bit normalized quantity and the most significant bit, which will always be 1 due to normalization, is implied. The Am9512 restores this implied bit internally before performing arithmetic; normalizes the result and strips the implied bit before returning the result to the external data bus. The binary point is between the implied bit and bit 51 of the mantissa.

The quantity N represented by the above notation is

$$N = (-1)^S 2^{E-(2^{10}-1)} (1.M)$$

Provided $E \neq 0$ or all 1's.

STATUS REGISTER

The Am9512 contains an 8-bit status register with the following format.

BUSY	SIGN S	ZERO Z	RESERVED	DIVIDE EXCEPTION D	EXPONENT UNDERFLOW U	EXPONENT OVERFLOW V	RESERVED
7	6	5	4	3	2	1	0

Bit 0 and bit 4 are reserved. Occurrence of exponent overflow (V), exponent underflow (U) and divide exception (D) are indicated by bits 1, 2 and 3 respectively. An attempt to divide by zero is the only divide exception. Bits 5 and 6 represent a zero result and the sign of a result respectively. Bit 7 (Busy) of the status register indicates if the Am9512 is currently busy executing a command. All the bits are initialized to zero upon reset. Also, executing a CLR (Clear Status) command will result in all zero status register bits. A zero in Bit 7 indicates that the Am9512 is not busy and a new command may be initiated. As soon as a new command is issued, Bit 7 becomes 1 to indicate the device is busy and remains 1 until the command execution is complete, at which time it will become 0. As soon as a new command is issued, status register bits 0, 1, 2, 3, 4, 5 and 6 are cleared to zero. The status bits will be set as required during the command execution. Hence, as long as bit 7 is 1, the remainder of the status register bit indications should not be relied upon unless the ERR occurs. The following is a detailed status bit description.

- Bit 0 Reserved
- Bit 1 Exponent overflow (V): When 1, this bit indicates that exponent overflow has occurred. Cleared to zero otherwise.
- Bit 2 Exponent Underflow (U): When 1, this bit indicates that exponent underflow has occurred. Cleared to zero otherwise.
- Bit 3 Divide Exception (D): When 1, this bit indicates that an attempt to divide by zero is made. Cleared to zero otherwise.
- Bit 4 Reserved
- Bit 5 Zero (Z): When 1, this bit indicates that the result returned to TOS after a command is all zeros. Cleared to zero otherwise.
- Bit 6 Sign (S): When 1, this bit indicates that the result returned to TOS is negative. Cleared to zero otherwise.
- Bit 7 Busy: When 1, this bit indicates the Am9512 is in the process of executing a command. It will become zero after the command execution is complete.

All other status register bits are valid when the Busy bit is zero.

ALGORITHMS OF FLOATING-POINT ARITHMETIC**1. Floating Point to Decimal Conversion**

As an introduction to floating-point arithmetic, a brief description of the Decimal equivalent of the Am9512 floating-point format should help the reader to understand and verify the validity of the arithmetic operations. The Am9512 single precision format is used for the following discussions. With a minor modification of the field lengths, the discussion would also apply to the double precision format:

There are three parts in a floating point number:

- a. The sign – the sign applies to the sign of the number. Zero means the number is positive or zero. One means the number is negative.

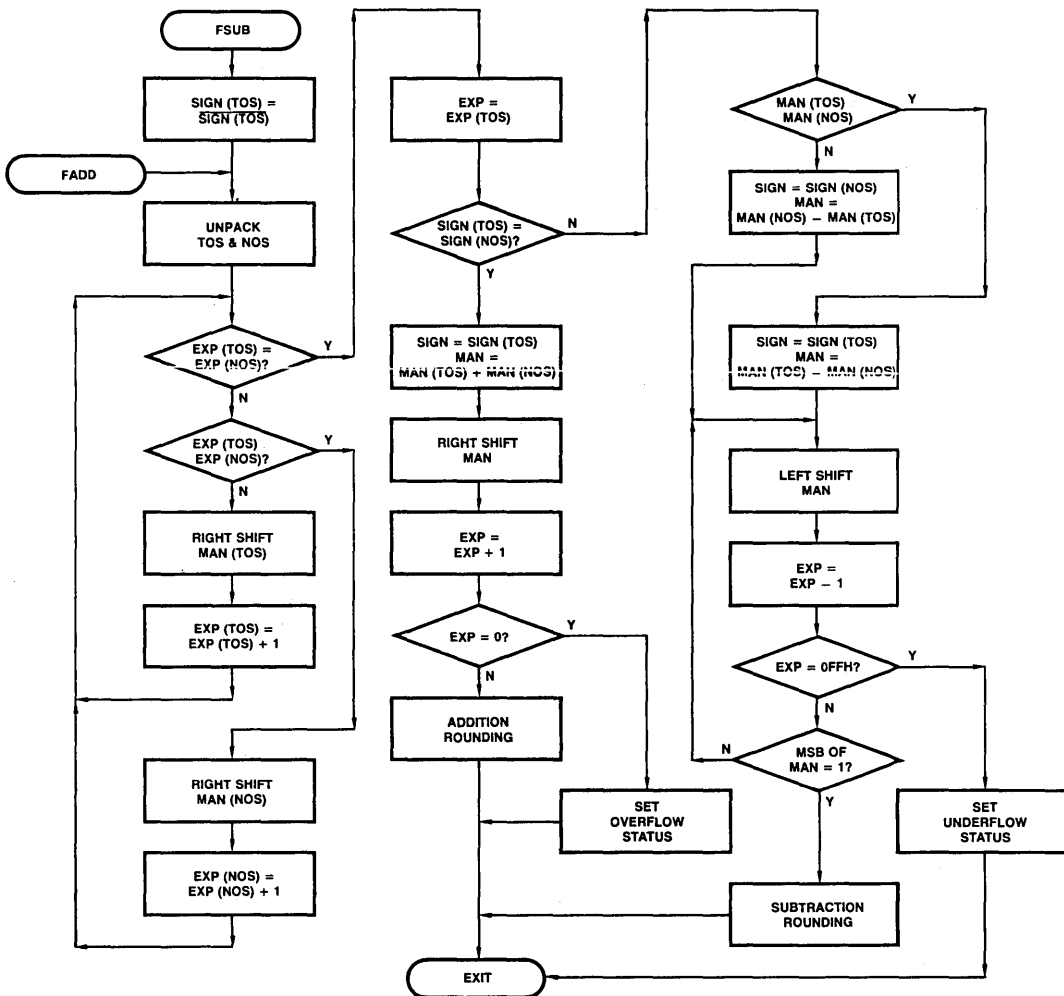

Figure 1. Conceptual Floating-Point Addition/Subtraction.

MOS-205

- h. Add bias to exponent of result.
 $EXP = EXP + 127_{10}$
- i. If sign of TOS = sign of NOS, set sign of result to 0, else set sign of result to 1.
- j. Divide mantissa of NOS by mantissa of TOS.
- k. If MSB = 0, left shift mantissa and decrement exponent of resultant, else go to n.
- l. If MSB of exponent changes from 0 to 1 as a result of the decrement, set underflow status.
- m. Go to k.
- n. Round if necessary and exit.

The algorithms described above provide the user a means of verifying the validity of the result. They do not necessarily reflect the exact internal sequence of the Am9512.

6. Rounding

The Am9512 adopts a rounding algorithm that is consistent with the Intel® standard for floating-point arithmetic. The following description is an excerpt from the paper published in proceedings of Compsac 77, November 1977, pp. 107-112 by Dr. John F. Palmer of Intel Corporation.

The method used for doing the rounding during floating-point arithmetic is known as "Round to Even", i.e., if the resultant number is exactly halfway between two floating point numbers, the number is rounded to the nearest floating-point number whose LSB of the mantissa is 0. In order to simplify the explanation, the algorithms will be illustrated with 4-bit arithmetic. The existence of an accumulator will be assumed as shown:

The bit labels denote:

- OF – The overflow bit
- B1-B4 – The 4 mantissa bits
- G – The Guard bit
- R – The Rounding bit
- ST – The "Sticky" bit

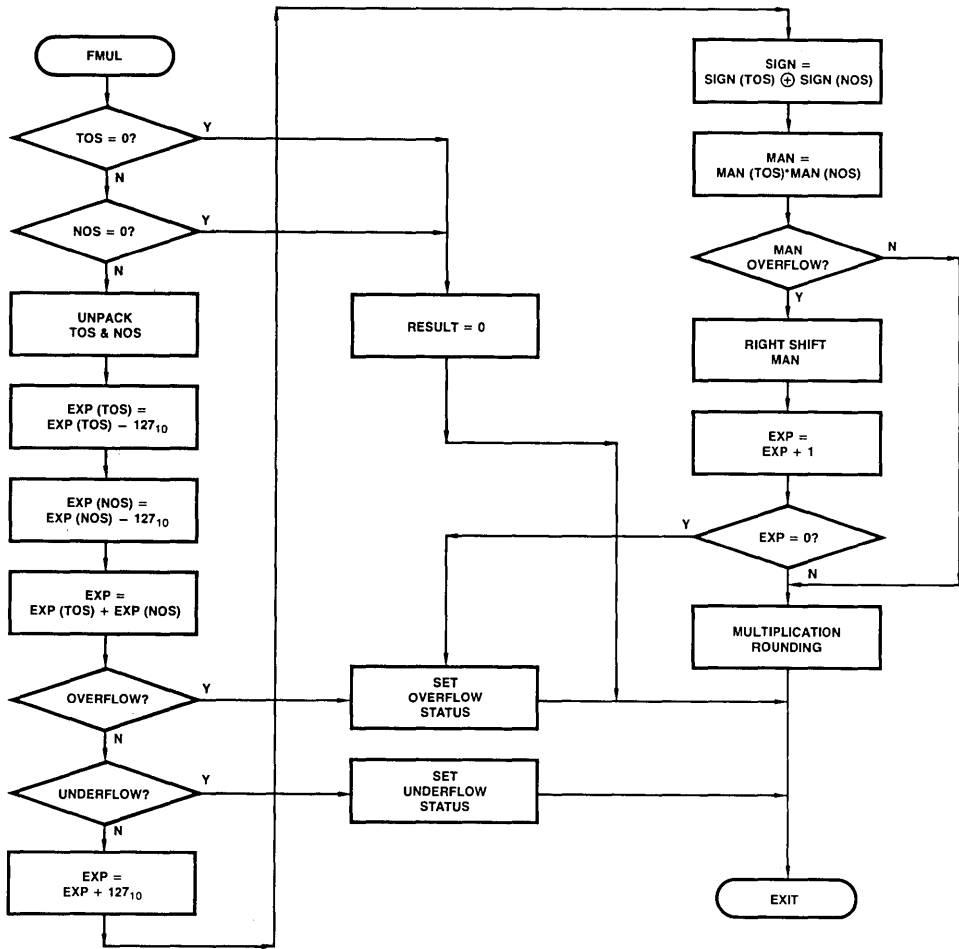

Figure 2. Conceptual Floating-Point Multiplication.

MOS-206

The Sticky bit is set to one if any ones are shifted right of the rounding bit in the process of denormalization. If the Sticky bit becomes set, it remains set throughout the operation. All shifting in the Accumulator involves the OF, G, R and ST bits. The ST bit is not affected by left shifts but, zeros are introduced into OF by right shifts.

Rounding during addition of magnitudes – add 1 to the G position, then if G=R=ST=0, set B4 to 0 (“Rounding to Even”).

Rounding during subtraction of magnitudes – if more than one left shift was performed, no rounding is needed, otherwise round the same way as addition of magnitudes.

Rounding during multiplication – let the normalized double length product be:

Then G=B5, R=B6, ST=B7 V B8. The rounding is then performed as in addition of magnitudes.

Rounding during division – let the first six bits of the normalized quotient be

Then G=B5, R=B6, ST=0 if and only if remainder = 0. The rounding is then performed as in addition of magnitudes.

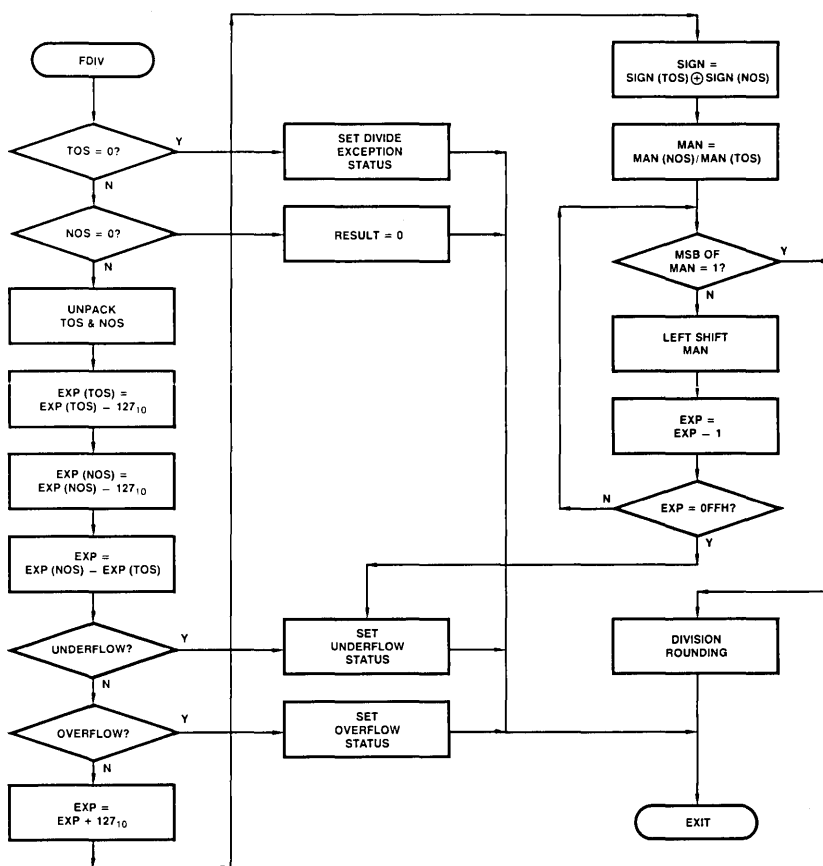

Figure 3. Conceptual Floating-Point Division.

-----	---	---	---	---	---	---	---

Hex Coding: AE IF SRE = 1
2E IF SRE = 0

Execution Time: See Table 2

Description:

The double precision operand A from the TOS is pushed back on to the stack. This is effectively a duplication of A into two consecutive stack locations. The status S and Z are affected to report sign of the new TOS and if the new TOS is zero respectively. The status bits U, V and D will be cleared to zero.

Status Affected: S, Z. (U, V, D always zero.)

STACK CONTENTS

PTOS

PUSH STACK SINGLE PRECISION

7 6 5 4 3 2 1 0

Binary Coding:

SRE	0	0	0	0	1	1	0
-----	---	---	---	---	---	---	---

Hex Coding: 86 IF SRE = 1
06 IF SRE = 0

Execution Time: See Table 2

Description:

This instruction effectively pushes the single precision operand from TOS on to the stack. This amounts to duplicating the operand at two locations in the stack. However, if the operand at TOS prior to the PTOS command has only its exponent field as zero, the new content of the TOS will all be zeroes. The contents of NOS will be an exact copy of the old TOS. The status bits S and Z are affected to report the sign of the new TOS and if the content of TOS is zero, respectively. The status bits U, V and D will be cleared to zero.

Status Affected: S, Z. (U, V, D always zero.)

STACK CONTENTS

Note: A* = A if Exponent field of A is not zero.
A* = 0 if Exponent field of A is zero.

MAXIMUM RATINGS beyond which useful life may be impaired

Storage Temperature	-65°C to +150°C
Ambient Temperature Under Bias	-55°C to +125°C
VDD with Respect to VSS	-0.5V to +15.0V
VCC with Respect to VSS	-0.5V to +7.0V
All Signal Voltages with Respect to VSS	-0.5V to +7.0V
Power Dissipation (Package Limitation)	2.0W

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulations of static charge. It is suggested, nevertheless, that conventional precautions be observed during storage, handling and use in order to avoid exposure to excessive voltages.

NOTES:

- Typical values are for $T_A = 25^\circ\text{C}$, nominal supply voltages and nominal processing parameters.
- Switching parameters are listed in alphabetical order.
- Test conditions assume transition times of 20ns or less, output loading of one TTL gate plus 100pF and timing reference levels of 0.8V and 2.0V.
- END HIGH pulse width is specified for \overline{EACK} tied to VSS. Otherwise TEAE applies.
- \overline{PAUSE} is pulled low for both command and data operations.
- TEX is the execution time of the current command (see the Command Execution Times table).

Am9517A

Multimode DMA Controller

DISTINCTIVE CHARACTERISTICS

- Four independent DMA channels, each with separate registers for Mode Control, Current Address, Base Address, Current Word Count and Base Word Count.
- Transfer modes: Block, Demand, Single Word, Cascade
- Independent autoinitialization of all channels
- Memory-to-memory transfers
- Memory block initialization
- Address increment or decrement
- Master system disable
- Enable/disable control of individual DMA requests
- Directly expandable to any number of channels
- End of Process input for terminating transfers
- Software DMA requests
- Independent polarity control for DREQ and DACK signals
- Compressed timing option speeds transfers – up to 2M words/second
- +5 volt power supply
- Advanced N-channel silicon gate MOS technology
- 40 pin Hermetic DIP package
- 100% MIL-STD-883 reliability assurance testing

GENERAL DESCRIPTION

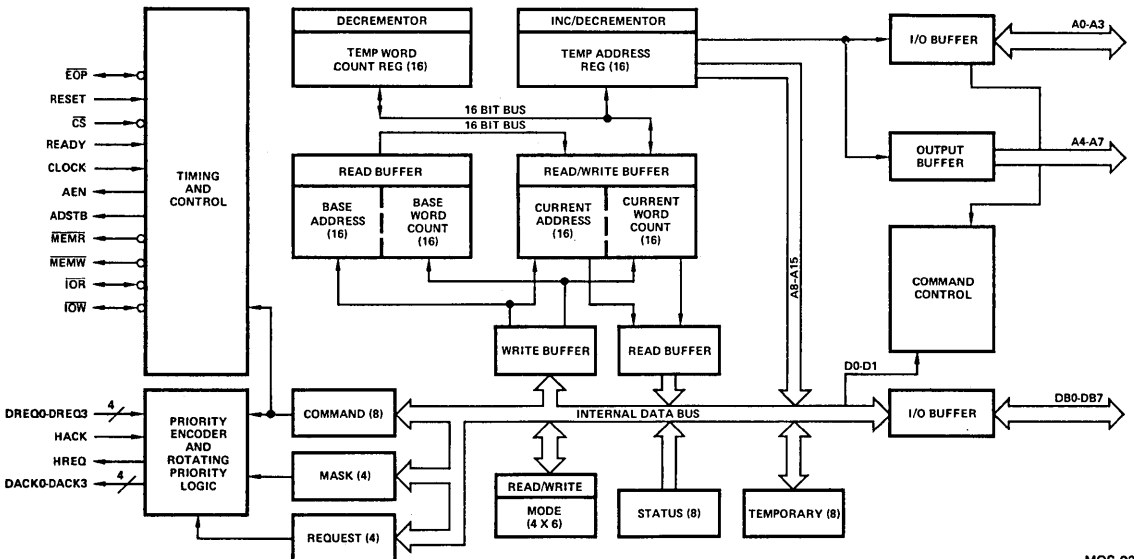

The Am9517A Multimode Direct Memory Access (DMA) Controller is a peripheral interface circuit for microprocessor systems. It is designed to improve system performance by allowing external devices to directly transfer information to or from the system memory. Memory-to-memory transfer capability is also provided. The Am9517A offers a wide variety of programmable control features to enhance data throughput and system optimization and to allow dynamic reconfiguration under program control.

The Am9517A is designed to be used in conjunction with an external 8-bit address register such as the Am74LS373. It contains four independent channels and may be expanded to any number of channels by cascading additional controller chips.

The three basic transfer modes allow programmability of the types of DMA service by the user. Each channel can be individually programmed to Autoinitialize to its original condition following an End of Process (EOP).

Each channel has a full 64K address and word count capability. An external EOP signal can terminate a DMA or memory-to-memory transfer. This is useful for block search or compare operations using external comparators or for intelligent peripherals to abort erroneous services.

MOS-034

INTERFACE SIGNAL DESCRIPTION

VCC: +5 Volt Supply

VSS: Ground

CLK (Clock, Input)

This input controls the internal operations of the Am9517A and its rate of data transfers. The input may be driven at up to 3MHz for the standard Am9517A and up to 4MHz for the Am9517A-4.

CS (Chip Select, Input)

Chip Select is an active low input used to select the Am9517A as an I/O device during an I/O Read or I/O Write by the host CPU. This allows CPU communication on the data bus. During multiple transfers to or from the Am9517A by the host CPU, CS may be held low providing IOR or IOW is toggled following each transfer.

RESET (Reset, Input)

Reset is an asynchronous active high input which clears the Command, Status, Request and Temporary registers. It also clears the first/last flip/flop and sets the Mask register. Following a Reset the device is in the Idle cycle.

READY (Ready, Input)

Ready is an input used to extend the memory read and write pulses from the Am9517A to accommodate slow memories or I/O peripheral devices.

HACK (Hold Acknowledge, Input)

The active high Hold Acknowledge from the CPU indicates that control of the system buses has been relinquished.

DREQ0-DREQ3 (DMA Request, Input)

The DMA Request lines are individual asynchronous channel request inputs used by peripheral circuits to obtain DMA service. In Fixed Priority, DREQ0 has the highest priority and DREQ3 has the lowest priority. Polarity of DREQ is programmable. Reset initializes these lines to active high.

DB0-DB7 (Data Bus, Input/Output)

The Data Bus lines are bidirectional three-state signals connected to the system data bus. The outputs are enabled during the I/O Read by the host CPU, permitting the CPU to examine

the contents of an Address register, the Status register, the Temporary register or a Word Count register. The Data Bus is enabled to input data during a host CPU I/O write, allowing the CPU to program the Am9517A control registers. During DMA cycles the most significant eight bits of the address are output onto the data bus to be strobed into an external latch by ADSTB. In memory-to-memory operations data from the source memory location comes into the Am9517A's Temporary register on the read-from-memory half of the operation. On the write-to-memory half of the operation, the data bus outputs the Temporary register data into the destination memory location.

IOR (I/O Read, Input/Output)

I/O Read is a bidirectional active low three-state line. In the Idle cycle, it is an input control signal used by the CPU to read the control registers. In the Active cycle, it is an output control signal used by the Am9517A to access data from a peripheral during a DMA Write transfer.

IOW (I/O Write, Input/Output)

I/O Write is a bidirectional active low three-state line. In the Idle cycle it is an input control signal used by the CPU to load information into the Am9517A. In the Active cycle it is an output control signal used by the Am9517A to load data to the peripheral during a DMA Read transfer.

Write operations by the CPU to the Am9517A require a rising WR edge following each data byte transfer. It is not sufficient to hold the IOW pin low and toggle CS.

EOP (End of Process, Input/Output)

EOP is an active low bidirectional open-drain signal providing information concerning the completion of DMA service. When a channel's Word Count goes to zero, the Am9517A pulses EOP low to provide the peripheral with a completion signal. EOP may also be pulled low by the peripheral to cause premature completion. The reception of EOP, either internal or external, causes the currently active channel to terminate the service, to set its TC bit in the Status register and to reset its request bit. If Autoinitialization is selected for the channel, the current registers will be updated from the base registers. Otherwise the channel's mask bit will be set and the register contents will remain unaltered.

4

During memory-to-memory transfers, \overline{EOP} will be output when the TC for channel 1 occurs. \overline{EOP} always applies to the channel with an active DACK; external \overline{EOP} s are disregarded in DACK0-DACK3 are all inactive.

Because \overline{EOP} is an open-drain signal, an external pullup resistor is required. Values of 3.3K or 4.7K are recommended; the \overline{EOP} pin can not sink the current passed by a 1K pullup.

A0-A3 (Address, Input/Output)

The four least significant address lines are bidirectional 3-state signals. During DMA Idle cycles they are inputs and allow the host CPU to load or read control registers. When the DMA is active, they are outputs and provide the lower 4-bits of the output address.

A4-A7 (Address, Output)

The four most significant address lines are three-state outputs and provide four bits of address. These lines are enabled only during DMA service.

HREQ (Hold Request, Output)

The Hold Request to the CPU is used by the DMA to request control of the system bus. Software requests or unmasked DREQs cause the Am9517A to issue HREQ.

DACK0-DACK3 (DMA Acknowledge, Output)

The DMA Acknowledge lines indicate that a channel is active. In many systems they will be used to select a peripheral. Only one DACK will be active at a time and none will be active unless the DMA is in control of the bus. The polarity of these lines is programmable. Reset initializes them to active-low.

AEN (Address Enable, Output)

Address Enable is an active high signal used to disable the system bus during DMA cycles to enable the output of the external latch which holds the upper byte of the address. Note that during DMA transfers HACK and AEN should be used to deselect all other I/O peripherals which may erroneously be accessed as programmed I/O during the DMA operation. The Am9517A automatically deselects itself by disabling the \overline{CS} input during DMA transfers.

ADSTB (Address Strobe, Output)

The active high Address Strobe is used to strobe the upper address byte from DB0-DB7 into an external latch.

MEMR (Memory Read, Output)

The Memory Read signal is an active low three-state output used to access data from the selected memory location during a memory-to-peripheral or a memory-to-memory transfer.

Name	Size	Number
Base Address Registers	16 bits	4
Base Word Count Registers	16 bits	4
Current Address Registers	16 bits	4
Current Word Count Registers	16 bits	4
Temporary Address Register	16 bits	1
Temporary Word Count Register	16 bits	1
Status Register	8 bits	1
Command Register	8 bits	1
Temporary Register	8 bits	1
Mode Registers	6 bits	4
Mask Register	4 bits	1
Request Register	4 bits	1

Figure 2. Am9517A Internal Registers.

MEMW (Memory Write, Output)

The Memory Write signal is an active low three-state output used to write data to the selected memory location during a peripheral-to-memory or a memory-to-memory transfer.

FUNCTIONAL DESCRIPTION

The Am9517A block diagram includes the major logic blocks and all of the internal registers. The data interconnection paths are also shown. Not shown are the various control signals between the blocks. The Am9517A contains 344 bits of internal memory in the form of registers. Figure 2 lists these registers by name and shows the size of each. A detailed description of the registers and their functions can be found under Register Description.

The Am9517A contains three basic blocks of control logic. The Timing Control block generates internal timing and external control signals for the Am9517A. The Program Command Control block decodes the various commands given to the Am9517A by the microprocessor prior to servicing a DMA Request. It also decodes each channel's Mode Control word. The Priority Encoder block resolves priority contention among DMA channels requesting service simultaneously.

The Timing Control block derives internal timing from the clock input. In Am9080A systems this input will usually be the $\phi 2$ TTL clock from an Am8224. However, any appropriate system clock will suffice.

DMA Operation

The Am9517A is designed to operate in two major cycles. These are called Idle and Active cycles. Each device cycle is made up of a number of states. The Am9517A can assume seven separate states, each composed of one full clock period. State 1 (S1) is the inactive state. It is entered when the Am9517A has no valid DMA requests pending. While in S1, the DMA controller is inactive but may be in the Program Condition, being programmed by the processor. State 0 (S0) is the first state of a DMA service. The Am9517A has requested a hold but the processor has not yet returned an acknowledge. An acknowledge from the CPU will signal that transfers may begin. S1, S2, S3 and S4 are the working states of the DMA service. If more time is needed to complete a transfer than is available with normal timing, wait states (SW) can be inserted before S4 by the use of the Ready line on the Am9517A.

Memory-to-memory transfers require a read-from and a write-to-memory to complete each transfer. The states, which resemble the normal working states, use two digit numbers for identification. Eight states are required for each complete transfer. The first four states (S11, S12, S13, S14) are used for the read-from-memory half and the last four states (S21, S22, S23 and S24) for the write-to-memory half of the transfer. The Temporary Data register is used for intermediate storage of the memory byte.

IDLE Cycle

When no channel is requesting service, the Am9517A will enter the Idle cycle and perform "S1" states. In this cycle the Am9517A will sample the DREQ lines every clock cycle to determine if any channel is requesting a DMA service. The device will also sample \overline{CS} , looking for an attempt by the microprocessor to write or read the internal registers of the Am9517A. When \overline{CS} is low and HACK is low the Am9517A enters the Program Condition. The CPU can now establish, change or inspect the internal definition of the part by reading from or writing to the internal registers. Address lines A0-A3 are inputs to the device and select which registers will be read or written. The \overline{IOR} and \overline{IOW} lines are used to select and time reads or writes. Due to the

number and size of the internal registers, an internal flip/flop is used to generate an additional bit of address. This bit is used to determine the upper or lower byte of the 16-bit Address and Word Count registers. The flip/flop is reset by Master Clear or Reset. A separate software command can also reset this flip/flop.

Special software commands can be executed by the Am9517A in the Program Condition. These commands are decoded as sets of addresses when both \overline{CS} and \overline{IOW} are active and do not make use of the data bus. Functions include Clear First/Last Flip/Flop and Master Clear.

ACTIVE CYCLE

When the Am9517A is in the Idle cycle and a channel requests a DMA service, the device will output a HREQ to the microprocessor and enter the Active cycle. It is in this cycle that the DMA service will take place, in one of four modes:

Single Transfer Mode: In Single Transfer mode, the Am9517A will make a one-byte transfer during each HREQ/HACK handshake. When DREQ goes active, HREQ will go active. After the CPU responds by driving HACK active, a one-byte transfer will take place. Following the transfer, HREQ will go inactive, the word count will be decremented and the address will be either incremented or decremented. When the word count goes to zero a Terminal Count (TC) will cause an Autoinitialize if the channel has been programmed to do so.

To perform a single transfer, DREQ must be held active only until the corresponding DACK goes active. If DREQ is held continuously active, HREQ will go inactive following each transfer and then will go active again and a new one-byte transfer will be made following each rising edge of HACK. In 8080A/9080A systems this will ensure one full machine cycle of execution between DMA transfers. Details of timing between the Am9517A and other bus control protocols will depend upon the characteristics of the microprocessor involved.

Block Transfer Mode: In Block Transfer mode, the Am9517A will continue making transfers until a TC (caused by the word count going to zero) or an external End of Process (EOP) is encountered. DREQ need be held active only until DACK becomes active. An autoinitialize will occur at the end of the service if the channel has been programmed for it.

Demand Transfer Mode: In Demand Transfer mode the device will continue making transfers until a TC or external EOP is encountered or until DREQ goes inactive. Thus, the device requesting service may discontinue transfers by bringing DREQ inactive. Service may be resumed by asserting an active DREQ once again. During the time between services when the microprocessor is allowed to operate, the intermediate values of address and word count may be read from the Am9517A Current Address and Current Word Count registers. Autoinitialization will only occur following a TC or EOP at the end of service. Following Autoinitialization, an active-going DREQ edge is required to initiate a new DMA service.

Cascade Mode: This mode is used to cascade more than one Am9517A together for simple system expansion. The HREQ and HACK signals from the additional Am9517A are connected to the DREQ and DACK signals of a channel of the initial Am9517A. This allows the DMA requests of the additional device to propagate through the priority network circuitry of the preceding device. The priority chain is preserved and the new device must wait for its turn to acknowledge requests. Since the cascade channel in the initial device is used only for prioritizing the additional device, it does not output any address or control

signals of its own. These would conflict with the outputs of the active channel in the added device. The Am9517A will respond to DREQ with DACK but all other outputs except HREQ will be disabled.

Figure 3 shows two additional devices cascaded into an initial device using two of the previous channels. This forms a two level DMA system. More Am9517As could be added at the second level by using the remaining channels of the first level. Additional devices can also be added by cascading into the channels of the second level devices forming a third level.

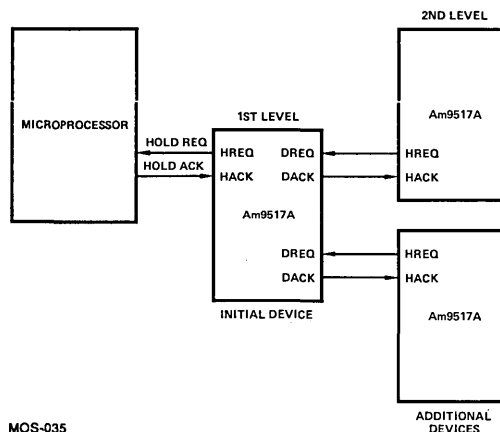

Figure 3. Cascaded Am9517As.

TRANSFER TYPES

Each of the three active transfer modes can perform three different types of transfers. These are Read, Write and Verify. Write transfers move data from an I/O device to the memory by activating \overline{IOR} and \overline{MEMW} . Read transfers move data from memory to an I/O device by activating \overline{MEMR} and \overline{IOW} . Verify transfers are pseudo transfers; the Am9517A operates as in Read or Write transfers generating addresses, responding to EOP, etc., however, the memory and I/O control lines remain inactive.

Memory-to-Memory: The Am9517A includes a block move capability that allows blocks of data to be moved from one memory address space to another. When Bit C0 in the Command register is set to a logical 1, channels 0 and 1 will operate as memory-to-memory transfer channels. Channel 0 forms the source address and channel 1 forms the destination address. The channel 1 word count is used. A memory-to-memory transfer is initiated by setting a software DMA request for channel 0. Block Transfer Mode should be used for memory-to-memory. When channel 0 is programmed for a fixed source address, a single source word may be written into a block of memory.

When setting up the Am9517A for memory-to-memory operation, it is suggested that both channels 0 and 1 be masked out. Further, the channel 0 word count should be initialized to the same value used in channel 1. No DACK outputs will be active during memory-to-memory transfers.

The Am9517A will respond to external \overline{EOP} signals during memory-to-memory transfers. Data comparators in block search schemes may use this input to terminate the service when a match is found. The timing of memory-to-memory transfers may be found in Timing Diagram 4.

Autoinitialize: By programming a bit in the Mode register a channel may be set up for an Autoinitialize operation. During Autoinitialization, the original values of the Current Address and Current Word Count registers are automatically restored from the Base Address and Base Word Count registers of that channel following EOP. The base registers are loaded simultaneously with the current registers by the microprocessor and remain unchanged throughout the DMA service. The mask bit is not set by $\overline{\text{EOP}}$ when the channel is in Autoinitialize. Following Autoinitialize the channel is ready to repeat its service without CPU intervention.

Priority: The Am9517A has two types of priority encoding available as software selectable options. The first is Fixed Priority which fixes the channels in priority order based upon the descending value of their number. The channel with the lowest priority is 3 followed by 2, 1 and the highest priority channel, 0.

The second scheme is Rotating Priority. The last channel to get service becomes the lowest priority channel with the others rotating accordingly. With Rotating Priority in a single chip DMA system, any device requesting service is guaranteed to be recognized after no more than three higher priority services have occurred. This prevents any one channel from monopolizing the system.

The priority encoder selects the highest priority channel requesting service on each active-going HACK edge. Once a channel is started, its operation will not be suspended if a request is received by a higher priority channel. The high priority channel will only gain control after the lower priority channel releases HREQ. When control is passed from one channel to another, the CPU will always gain bus control. This ensures generation of rising HACK edge to be used to initiate selection of the new highest-priority requesting channel.

Compressed Timing: In order to achieve even greater throughput where system characteristics permit, the Am9517A can compress the transfer time to two clock cycles. From Timing Diagram 3 it can be seen that state S3 is used to extend the access time of the read pulse. By removing state S3 the read pulse width is made equal to the write pulse width and a transfer consists only of state S2 to change the address and state S4 to perform the read/write. S1 states will still occur when A8-A15 need updating (see Address Generation). Timing for compressed transfers is found in Timing Diagram 6.

Address Generation: In order to reduce pin count, the Am9517A multiplexes the eight higher order address bits on the data lines. State S1 is used to output the higher order address

bits to an external latch from which they may be placed on the address bus. The falling edge of Address Strobe (ADSTB) is used to load these bits from the data lines to the latch. Address Enable (AEN) is used to enable the bits onto the address bus through a 3-state enable. The lower order address bits are output by the Am9517A directly. Lines A0-A7 should be connected to the address bus. Timing Diagram 3 shows the time relationships between CLK, AEN, ADSTB, DB0-DB7 and A0-A7.

During Block and Demand Transfer mode services which include multiple transfers, the addresses generated will be sequential. For many transfers the data held in the external address latch will remain the same. This data need only change when a carry or borrow from A7 to A8 takes place in the normal sequence of addresses. To save time and speed transfers, the Am9517A executes S1 states only when updating of A8-A15 in the latch is necessary. This means for long services, S1 states may occur only once every 256 transfers, a savings of 255 clock cycles for each 256 transfers.

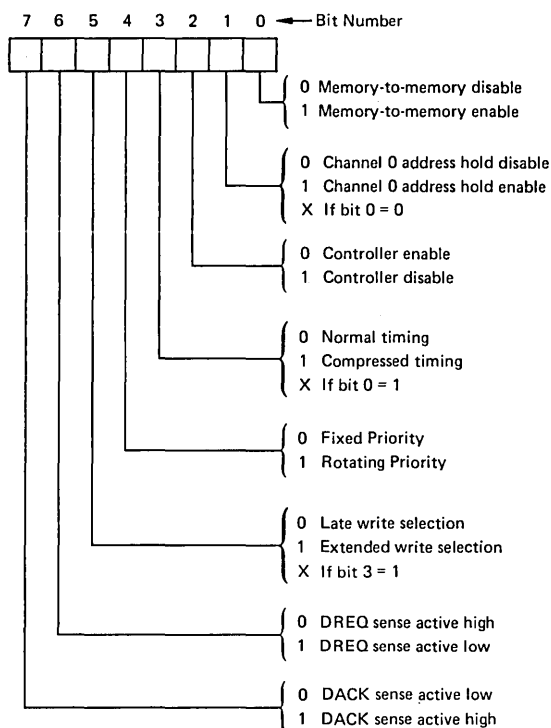

REGISTER DESCRIPTION

Current Address Register: Each channel has a 16-bit Current Address register. This register holds the value of the address used during DMA transfers. The address is automatically incremented or decremented after each transfer and the intermediate values of the address are stored in the Current Address register during the transfer. This register is written or read by the microprocessor in successive 8-bit bytes. It may also be reinitialized by an Autoinitialize back to its original value. Autoinitialization takes place only after an $\overline{\text{EOP}}$.

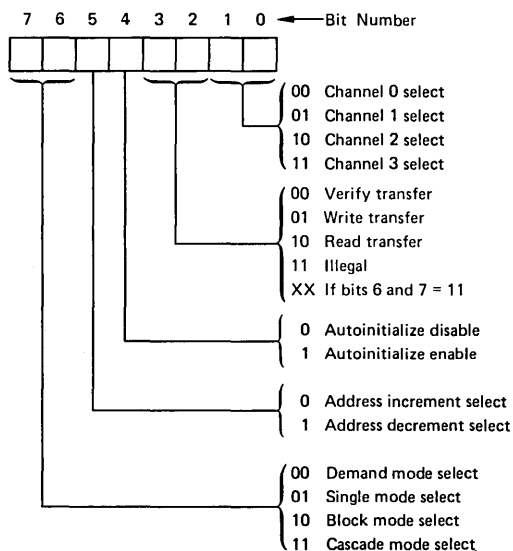

Current Word Count Register: Each channel has a 16-bit Current Word Count register. This register should be programmed with, and will return on a CPU read, a value one less than the number of words to be transferred. The word count is decremented after each transfer. The intermediate value of the word count is stored in the register during the transfer. When the value in the register goes to zero, a TC will be generated. This register is loaded or read in successive 8-bit bytes by the microprocessor in the Program Condition. Following the end of a DMA service it may also be reinitialized by an Autoinitialize back to its original value. Autoinitialize can occur only when an $\overline{\text{EOP}}$ occurs. Note that the contents of the Word Count register will be FFFF (hex) following an internally generated $\overline{\text{EOP}}$.

Base Address and Base Word Count Registers: Each channel has a pair of Base Address and Base Word Count registers. These 16-bit registers store the original values of their associated current registers. During Autoinitialize these values are used to restore the current registers to their original values. The base registers are written simultaneously with their corresponding current register in 8-bit bytes during DMA programming by the microprocessor. Accordingly, writing to these registers when intermediate values are in the Current registers will overwrite the intermediate values. The Base registers cannot be read by the microprocessor.

Command Register: This 8-bit register controls the operation of the Am9517A. It is programmed by the microprocessor in the Program Condition and is cleared by Reset. The following table lists the function of the command bits. See Figure 4 for address coding.

Mode Register: Each channel has a 6-bit Mode register associated with it. When the register is being written to by the microprocessor in the Program Condition, bits 0 and 1 determine which channel Mode register it to be written.

Request Register: The Am9517A can respond to requests for DMA service which are initiated by software as well as by a DREQ. Each channel has a request bit associated with it in the 4-bit Request register. These are nonmaskable and subject to prioritization by the Priority Encoder network. Each register bit is set or reset separately under software control or is cleared upon generation of a TC or external EOP. The entire register is cleared by a Reset. To set or reset a bit, the software loads the proper form of the data word. See Figure 4 for address coding.

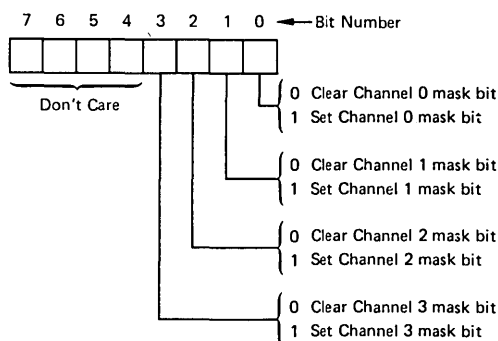

Software requests will be serviced only if the channel is in Block mode. When initiating a memory-to-memory transfer, the software request for channel 0 should be set.

Mask Register: Each channel has associated with it a mask bit which can be set to disable the incoming DREQ. Each mask bit is set when its associated channel produces an EOP if the channel is not programmed for Autoinitialize. Each bit of the 4-bit Mask register may also be set or cleared separately under software control. The entire register is also set by a Reset. This disables all DMA requests until a clear Mask register instruction allows them to occur. The instruction to separately set or clear the mask bits is similar in form to that used with the Request register. See Figure 4 for instruction addressing.

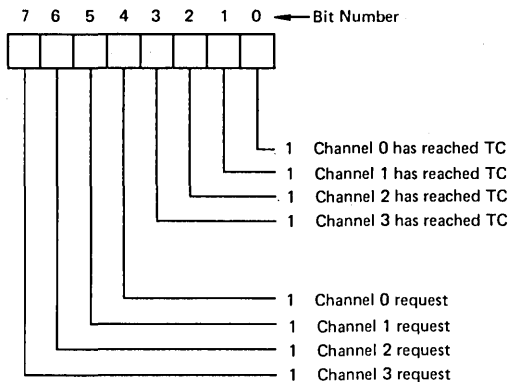

All four bits of the Mask Register may also be written with a single command.

4

Status Register: The Status registers may be read out of the Am9517A by the microprocessor. It indicates which channels have reached a terminal count and which channels have pending DMA requests. Bits 0-3 are set each time a TC is reached by that channel, including after each Autoinitialization. These bits are cleared by Reset and each Status Read. Bits 4-7 are set whenever their corresponding channel is requesting service.

Temporary Register: The Temporary register is used to hold data during memory-to-memory transfers. Following the completion of the transfers, the last word moved can be read by the microprocessor in the Program Condition. The Temporary register always contains the last byte transferred in the previous memory-to-memory operation, unless cleared by a Reset.

Software Commands: There are two special software commands which can be executed in the Program Condition. They do not depend on any specific bit pattern on the data bus. The two software commands are:

Clear First/Last Flip/Flop: This command may be issued prior to writing or reading Am9517A address or word count information. This initializes the flip/flop to a known state so that subsequent accesses to register contents by the microprocessor will address lower and upper bytes in the correct sequence.

Master Clear: This software instruction has the same effect as the hardware Reset. The Command, Status, Request, Temporary and Internal First/Last Flip/Flop registers are cleared and the Mask register is set. The Am9517A will enter the Idle cycle.

Figure 4 lists the address codes for the software commands.

Interface Signals						Operation
A3	A2	A1	A0	$\overline{\text{IOR}}$	$\overline{\text{IOW}}$	
1	0	0	0	0	1	Read Status Register

Am9517A

MAXIMUM RATINGS above which useful life may be impaired

Storage Temperature	-65°C to +150°C
Ambient Temperature Under Bias	-55°C to +125°C
VCC with Respect to VSS	-0.5V to +7.0V
All Signal Voltages with Respect to VSS	-0.5V to +7.0V
Power Dissipation (Package Limitation)	1.5W

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulations of static charge. It is suggested, nevertheless, that conventional precautions be observed during storage, handling and use in order to avoid exposure to excessive voltages.

OPERATING RANGE

Part Number	T _A	VCC
Am9517ADC/PC	0°C to +70°C	5.0V ±5%
Am9517A-1DC/PC	0°C to +70°C	5.0V ±5%
Am9517A-4DC/PC	0°C to +70°C	5.0V ±5%
Am9517ADM	-55°C to +125°C	5.0V ±10%

ELECTRICAL CHARACTERISTICS over operating range (Note 1)

Parameter	Description	Test Conditions	Min	Typ	Max	Unit
VOH	Output HIGH Voltage	I _{OH} = -200μA	2.4			Volts
		I _{OH} = -100μA, (HREQ Only)	3.3			
VOL	Output LOW Voltage	I _{OL} = 3.2mA			0.4	Volts
VIH	Input HIGH Voltage		2.0		VCC+0.5	Volts
VIL	Input LOW Voltage		-0.5		0.8	Volts
IIX	Input Load Current	VSS ≤ VI ≤ VCC	-10		+10	μA
IOZ	Output Leakage Current	VCC ≤ VO ≤ VSS+4.0	-10		+10	μA
ICC	VCC Supply Current	T _A = +25°C		65	130	mA
		T _A = 0°C		75	150	
		T _A = -55°C			175	
CO	Output Capacitance	fc = 1.0MHz, Inputs = 0V		4	8	pF
CI	Input Capacitance			8	15	pF
CIO	I/O Capacitance			10	18	pF

NOTES:

- Typical values are for T_A = 25°C, nominal supply voltage and nominal processing parameters.
- Input timing parameters assume transition times of 20ns or less. Waveform measurement points for both input and output signals are 2.0V for High and 0.8V for Low, unless otherwise noted.
- Output loading is 1 Standard TTL gate plus 50pF capacitance unless noted otherwise.
- The new \overline{IOW} or \overline{MEMW} pulse width for normal write will be TCY-100ns and for extended write will be 2TCY-100ns. The net \overline{IOR} or \overline{MEMR} pulse width for normal read will be 2TCY-50ns and for compressed read will be TCY-50ns.
- TDQ is specified for two different output HIGH levels. TDQ1 is measured at 2.0V. TDQ2 is measured at 3.3V. The value for TDQ2 assumes an external 3.3kΩ pull-up resistor connected from HREQ to VCC.
- DREQ should be held active until DACK is returned.
- DREQ and DACK signals may be active high or active low. Timing diagrams assume the active high mode.
- Output loading on the data bus is 1 Standard TTL gate plus 15pF for the minimum value and 1 Standard TTL gate plus 100pF for the maximum value.
- Successive read and/or write operations by the external processor to program or examine the controller must be timed to allow at least 600ns for the Am9517A or Am9517A-1 and at least 450ns for the Am9517A-4 as recovery time between active read or write pulses.
- Parameters are listed in alphabetical order.
- Pin 5 is an input that should always be at a logic high level. An internal pull-up resistor will establish a logic high when the pin is left floating. Alternatively, pin 5 may be tied to VCC.
- Signals \overline{READ} and \overline{WRITE} refer to \overline{IOR} and \overline{MEMW} respectively for peripheral-to-memory DMA operations and to \overline{MEMR} and \overline{IOW} respectively for memory-to-peripheral DMA operations.
- If N wait states are added during the write-to-memory half of a memory-to-memory transfer, this parameter will increase by N (TCY).

SWITCHING CHARACTERISTICS

ACTIVE CYCLE (Notes 2, 3, 10, 11 and 12)

Parameter	Description	Am9517A		Am9517A-1		Am9517A-4		Unit
		Min	Max	Min	Max	Min	Max	
T AEL	AEN HIGH from CLK LOW (S1) Delay Time		300		300		225	ns
T AET	AEN LOW from CLK HIGH (S1) Delay Time		200		200		150	ns

APPLICATION INFORMATION

Figure 6 shows a convenient method for configuring a DMA system with the Am9517A Controller and a microprocessor system. The Multimode DMA Controller issues a Hold Request to the processor whenever there is at least one valid DMA Request from a peripheral device. When the processor replies with a Hold Acknowledge signal, the Am9517A takes control of the Address Bus, the Data Bus and the Control Bus. The address for the first transfer operation comes out in two bytes – the least significant eight bits on the eight Address outputs and the most

significant eight bits on the Data Bus. The contents of the Data Bus are then latched into the Am74LS373 register to complete the full 16 bits of the Address Bus. The Am74LS373 is a high speed, low power, 8-bit, 3-state register in a 20-pin package. After the initial transfer takes place, the register is updated only after a carry or borrow is generated in the least significant address byte. Four DMA channels are provided when one Am9517A is used.

Universal Interrupt Controller

DISTINCTIVE CHARACTERISTICS

- Eight individually maskable interrupt inputs
- Software interrupt request capability
- Fully programmable 1, 2, 3 or 4 byte responses
- Unlimited daisy-chain expansion capability
- Fixed or rotating priority resolution
- Common vector option
- Polled mode option
- Optional automatic clearing of acknowledged interrupts
- Bit set/reset capability for Mask register
- Master Mask bit disables all interrupts
- Pulse-catching interrupt input circuitry
- Polarity control of interrupt inputs and output
- Various timing options including 8085A compatible Am9519-1
- Single +5V supply
- 100% MIL-STD-883 reliability assurance testing

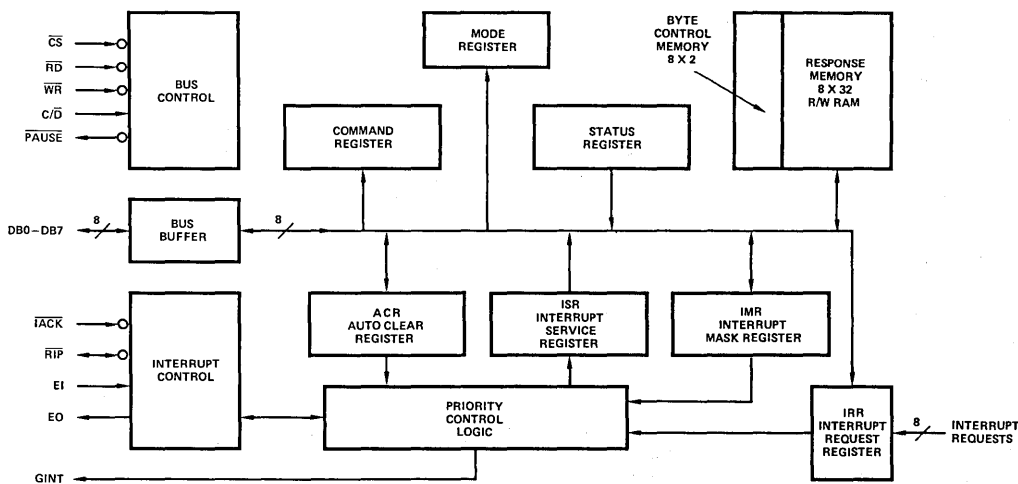

GENERAL DESCRIPTION

The Am9519 Universal Interrupt Controller is a processor support circuit that provides a powerful interrupt structure to increase the efficiency and versatility of microcomputer-based systems. A single Am9519 manages up to eight maskable interrupt request inputs, resolves priorities and supplies up to four bytes of fully programmable response for each interrupt. It uses a simple expansion structure that allows many units to be cascaded for control of large numbers of interrupts. Several programmable control features are provided to enhance system flexibility and optimization.

The Universal Interrupt Controller is designed with a general purpose interface to facilitate its use with a wide range of digital systems, including most popular 8-bit microprocessors. Since the response bytes are fully programmable, any instruction or vectoring protocol appropriate for the host processor may be used.

When the Am9519 controller receives an unmasked Interrupt Request, it issues a Group Interrupt output to the CPU. When the interrupt is acknowledged, the controller outputs the one-to-four byte response associated with the highest priority unmasked interrupt request. The ability of the CPU to set interrupt requests under software control permits hardware prioritization of software tasks and aids system diagnostic and maintenance procedures.

MOS-019

INTERFACE SIGNAL DESCRIPTION

VCC: +5 Volt Power Supply**VSS:** Ground**DB0 – DB7 (Data Bus, Input/Output)**

The eight bidirectional data bus signals are used to transfer information between the Am9519 and the system data bus. The direction of transfer is controlled by the $\overline{\text{IACK}}$, $\overline{\text{WR}}$ and $\overline{\text{RD}}$ input signals. Programming and control information are written into the device; status and response data are output by it.

 $\overline{\text{CS}}$ (Chip Select, Input)

The active low Chip Select input enables read and write operations on the data bus. Interrupt acknowledge responses are not conditioned by $\overline{\text{CS}}$.

 $\overline{\text{RD}}$ (Read, Input)

The active low Read signal is conditioned by $\overline{\text{CS}}$ and indicates that information is to be transferred from the Am9519 to the data bus.

 $\overline{\text{WR}}$ (Write, Input)

The active low Write signal is conditioned by $\overline{\text{CS}}$ and indicates that data bus information is to be transferred from the data bus to a location within the Am9519.

 $\text{C}/\overline{\text{D}}$ (Control/Data, Input)

The $\text{C}/\overline{\text{D}}$ control signal selects source and destination locations for data bus read and write operations. Data read or write transfers are made to or from preselected internal registers or memory locations. Control write operations load the command register and control read operations output the status register.

IREQ0 – IREQ7 (Interrupt Request, Input)

The Interrupt Request signals are used by external devices to indicate that service by the host CPU is desired. IREQ inputs are accepted asynchronously and they may be programmed for either a high-to-low or low-to-high

edge transition. Active inputs are latched internally in the Interrupt Request Register. After the IRR bit is cleared, an IREQ transition of the programmed polarity must occur to initiate another request.

 $\overline{\text{RIP}}$ (Response In Process, Input/Output)

Response In Process is a bidirectional signal used when two or more Am9519 circuits are cascaded. It permits multibyte response transfers to be completed without interference from higher priority interrupts. An Am9519 that is responding to an acknowledged interrupt will treat $\overline{\text{RIP}}$ as an output and hold it low until the acknowledge response is finished. An Am9519 without an acknowledged interrupt will treat $\overline{\text{RIP}}$ as an input and will ignore $\overline{\text{IACK}}$ pulses as long as $\overline{\text{RIP}}$ is low. The $\overline{\text{RIP}}$ output is open drain and requires an external pullup resistor to VCC.

 $\overline{\text{IACK}}$ (Interrupt Acknowledge, Input)

The active low Interrupt Acknowledge line indicates that the external system is asking for interrupt response information. Depending on the programmed state of the Am9519, it will accept 1, 2, 3 or 4 $\overline{\text{IACK}}$ pulses; one response byte is transferred per pulse. The first $\overline{\text{IACK}}$ pulse causes selection of the highest priority unmasked pending interrupt request and generates a $\overline{\text{RIP}}$ output signal.

 $\overline{\text{PAUSE}}$ (Pause, Output)

The active-low Pause signal is used to coordinate interrupt responses with data bus and control timing. Pause goes low when the first $\overline{\text{IACK}}$ is received and remains low until $\overline{\text{RIP}}$ goes low. The external system can use Pause to stretch the acknowledge cycle and allow the control timing to automatically adjust to the actual priority resolution delays in the interrupt system. Second, third and fourth response bytes do not cause Pause to go low. Pause is an open drain output and requires an external pullup resistor to VCC.

EO (Enable Out, Output)

The active high EO signal is used to implement daisy-chained cascading of several Am9519 circuits. EO is connected to the EI input of the next lower priority chip. On receipt of an interrupt acknowledge, each EO will go inactive until it has been determined that no valid interrupt request is pending on that chip. If an active request is present, EO remains low. EO is also held low when the master mask bit is active, thus disabling all lower priority chips.

EI (Enable In, Input)

The active high EI signal is used to implement daisy-chained cascading of several Am9519 circuits. EI is connected to EO of the next higher priority chip. It may also be used as a hardware disable input for the interrupt system. When EI is low $\overline{\text{IACK}}$ inputs are ignored. EI is internally pulled up to VCC so that no external pullup is needed when EI is not used.

GINT (Group Interrupt, Output)

The Group Interrupt output signal indicates that at least one unmasked interrupt request is pending. It may be programmed for active high or active low polarity. When active low, the output is open drain and requires an external pull up resistor to VCC.

REGISTER DESCRIPTION

Interrupt Request Register (IRR): The 8-bit IRR is used to store pending interrupt requests. A bit in the IRR is set whenever the corresponding IREQ input goes active. Bits may also be set under program control from the CPU, thus permitting software generated interrupts. IRR bits may be cleared under program control. An IRR bit is automatically cleared when its interrupt is acknowledged. All IRR bits are cleared by a reset function.

Interrupt Service Register (ISR): The 8-bit ISR contains one bit for each IREQ input. It is used to indicate that a pending interrupt has been acknowledged and to mask all lower priority interrupts. When a bit is set by the acknowledge logic in the ISR, the corresponding IRR bit is cleared. If an acknowledged interrupt is not programmed to be automatically cleared, its ISR bit must be cleared by the CPU under program control when it is desired to permit interrupts from lower priority devices. When the interrupt is programmed for automatic clearing, the ISR bit is automatically reset during the acknowledge sequence. All ISR bits are cleared by a reset function.

Interrupt Mask Register (IMR): The 8-bit IMR is used to enable or disable the individual interrupt inputs. The IMR bits correspond to the IREQ inputs and all eight may be loaded, set or cleared in parallel under program control. In addition, individual IMR bits may be set or cleared by the CPU. A reset function will set all eight mask bits, disabling all requests. A mask bit that is set does not disable the IRR, and an IREQ that arrives while a corresponding mask bit is set will cause an interrupt later when the mask bit is cleared. Only unmasked interrupt inputs can generate a Group Interrupt output.

Response Memory: An 8 x 32 read/write response memory is included in the Am9519. It is used to store up to four bytes of response information for each of the eight interrupt request inputs. All bits in the memory are programmable, allowing any desired vector, opcode, instruction or other data to be entered. The Am9519 transfers the interrupt response information for the highest priority unmasked interrupt from the memory to the data bus when the $\overline{\text{IACK}}$ input is active.

Auto Clear Register: The 8-bit Auto Clear register contains one bit for each IREQ input and specifies the operating mode for each of the ISR bits. When an auto clear bit is off, the corresponding ISR bit is set when that interrupt is acknowledged and is cleared by software command. When an auto clear bit is on, the corresponding ISR bit is cleared by the hardware before the end of the acknowledge sequence. A reset function clears all auto clear bits.

Status Register: The 8-bit Status register contains information concerning the internal state of the chip. It is especially useful when operating in the polled mode in order to identify interrupting devices. Figure 1 shows the status register bit assignments. The polarity of the GINT bit 7 is not affected by the GINT polarity control (Mode bit 3). The Status register is read by executing a read operation ($\overline{\text{CS}} = 0, \overline{\text{RD}} = 0$) with the control location selected ($\text{C}/\overline{\text{D}} = 1$).

Mode Register: The 8-bit Mode register controls the operating options of the Am9519. Figure 2 shows the bit assignments for the Mode register. The five low order mode bits (0 through 4) are loaded in parallel by command. Bits 5, 6 and 7 are controlled by separate commands. (See Figure 4.) The Mode register cannot be read out directly to the data bus, but Mode bits 0, 2 and 7 are available as part of the Status register.

Command Register: The 8-bit Command register stores the last command entered. Depending upon the command opcode, it may initiate internal actions or precondition the part for subsequent data bus transfers. The Command register is loaded by executing a write operation ($\overline{\text{WR}} = 0$) with the control location selected ($\text{C}/\overline{\text{D}} = 1$), as shown in Figure 3.

Byte Count Register: The length in bytes of the response associated with each interrupt is independently programmed so that different interrupts may have different length responses. The byte count for each response is stored in eight 2-bit Byte Count registers. For a given interrupt the Am9519 will expect to receive a number of $\overline{\text{IACK}}$ pulses that equals the corresponding byte count, and will hold RIP low until the count is satisfied.

MOS-026

FUNCTIONAL DESCRIPTION

Interrupts are used to improve system throughput and response time by eliminating heavy dependence on software polling procedures. Interrupts allow external devices to asynchronously modify the instruction sequence of a program being executed. In systems with multiple interrupts, vectoring can further improve performance by allowing direct identification of the interrupting device and its associated service routine. The Am9519 Universal Interrupt Controller contains, on one chip, all of the circuitry necessary to detect, prioritize and manage eight vectored interrupts. It includes many options and operating modes that permit the design of sophisticated interrupt systems.

Reset

The reset function is accomplished by software command or automatically during power-up. The reset command may be issued by the CPU at any time. Internal power up circuitry is triggered when VCC reaches a predetermined threshold, causing a brief internal reset pulse. In both cases, the resulting internal state of the machine is that all registers are cleared except the Mask register which is set. Thus no Group Interrupt will be generated and no interrupt requests will be recognized. The response memory and Byte Count registers are not affected by reset. Their contents after power-up are unpredictable and must be established by the host CPU during initialization.

Operating Sequence

A brief description of a typical sequence of events in an operating interrupt system will illustrate the general interactions among the host CPU, the interrupt controller and the interrupting peripheral.

1. The Am9519 controller is initialized by the CPU in order to customize its configuration and operation for the application at hand. Both the controller and the CPU are then enabled to accept interrupts.

2. One (or more) of the interrupt request inputs to the controller becomes active indicating that peripheral equipment is asking for service. The controller asynchronously accepts and latches the request(s).
3. If the request is masked, no further action takes place. If the request is not masked, a Group Interrupt output is generated by the controller.
4. The GINT signal is recognized by the CPU which normally will complete the execution of the current instruction, insert an interrupt acknowledge sequence into its instruction execution stream, and disable its internal interrupt structure. The controller expects to receive one or more \overline{IACK} signals from the CPU during the acknowledge sequence.
5. When the controller receives the \overline{IACK} signal, it brings \overline{PAUSE} low and selects the highest priority unmasked pending request. When selection is complete, the \overline{RIP} output is brought low and the first byte in the response memory associated with the selected request is output on the data bus. \overline{PAUSE} stays low until \overline{RIP} goes low. \overline{RIP} stays low until the last byte of the response has been transferred.
6. During the acknowledge sequence, the IRR bit corresponding to the selected request is automatically cleared, and the corresponding ISR bit is set. When the ISR bit is set, the Group Interrupt output is disabled until a higher priority request arrives or the ISR bit is cleared. The ISR bit will be cleared by either hardware or software.
7. If a higher priority request arrives while the current request is being serviced, GINT will be output by the controller, but will be recognized and acknowledged only if the CPU has its interrupt input enabled. If acknowledged, the corresponding higher priority ISR bit will be set and the requests nested.

4

Information Transfers

Figure 3 shows the control signal configurations for all information transfer operations between the Am9519 and the data bus. The following conventions are assumed: \overline{RD} and \overline{WR} active are mutually exclusive; \overline{RD} , \overline{WR} and C/\overline{D} have no meaning unless \overline{CS} is low; active \overline{IACK} pulses occur only when \overline{CS} is high.

For reading, the Status register is selected directly by the C/\overline{D} control input. Other internal registers are read by preselecting the desired register with mode bits 5 and 6, and then executing a data read. The response memory can be read only with \overline{IACK} pulses. For writing, the Command register is selected directly by the C/\overline{D} control input. The Mask and Auto Clear registers are loaded following specific commands to that effect. To load each level of the response memory, the response preselect command is issued to select the desired level. An appropriate number of data write operations are then executed to load that level.

CONTROL INPUT					DATA BUS OPERATION
\overline{CS}	C/\overline{D}	\overline{RD}	\overline{WR}	\overline{IACK}	
0	0	0	1	1	Transfer contents of preselected data register to data bus
0	0	1	0	1	Transfer contents of data bus to preselected data register
0	1	0	1	1	Transfer contents of status register to data bus
0	1	1	0	1	Transfer contents of data bus to command register
1	X	X	X	0	Transfer contents of selected response memory location to data bus
1	X	X	X	1	No information transferred

Figure 3. Summary of Data Bus Transfers.

The Pause output may be used by the host CPU to ensure that proper timing relationships are maintained with the Am9519 when \overline{IACK} is active. The \overline{IACK} pulse width required depends on several variables, including: operating temperature, internal logic delays, number of interrupt controllers chained together, and the priority level of the interrupt being acknowledged. When delays in these variables combine to delay selection of a request following the falling edge of the first \overline{IACK} , the Pause output may be used to extend the \overline{IACK} pulse, if necessary. Pause will remain low until a request has been selected, as indicated by the falling edge of \overline{RIP} . Typically, the internal interrupt selection process is quite fast, especially for systems with a single Am9519, and Pause will consequently remain low for only a very brief interval and will not cause extension of the \overline{IACK} timing.

Operating Options

The Mode register specifies the various combinations of operating options that may be selected by the CPU. It is cleared by power-up or by a reset command.

Mode bit 0 specifies the rotating/fixed priority mode (see Figure 2). In the fixed mode, priority is assigned to the request inputs based upon their physical location at the

chip interface, with $\overline{IREQ0}$ the highest and $\overline{IREQ7}$ the lowest. In the rotating mode, relative priority is the same as for the fixed mode and the most recently serviced request is assigned the lowest priority. In the fixed mode, a lower priority request might never receive service if enough higher priority requests are active. In the rotating mode, any request will receive service within a maximum of seven other service cycles no matter what pattern the request inputs follow.

Mode bit 1 selects the individual/common vector option. Individual vectoring provides a unique location in the response memory for each interrupt request. The common vector option always supplies the response associated with $\overline{IREQ0}$ no matter which request is being acknowledged.

Mode bit 2 specifies interrupt or polled operation. In the polled mode the Group Interrupt output is disabled. The CPU may read the Status register to determine if a request is pending. Since \overline{IACK} pulses are not normally supplied in polled mode, the \overline{IRR} bit is not automatically cleared, but may be cleared by command. With no \overline{IACK} input the ISR and the response memory are not used. An Am9519 in the polled mode has EI connected to EO so that in multichip interrupt systems the polled chip is functionally removed from the priority hierarchy.

Mode bit 3 specifies the sense of the GINT output. When active high polarity is selected the output is a two-state configuration. For active low polarity, the output is open drain and requires an external pull-up resistor to provide the high logic level. The open drain output allows wired-or configurations with other similar output signals.

Mode bit 4 specifies the sense of the \overline{IREQ} inputs. When active low polarity is selected, the \overline{IRR} responds to falling edges on the request inputs. When active high is selected, the \overline{IRR} responds to rising edges.

Mode bits 5 and 6 specify the register that will be read on subsequent data read operations ($C/\overline{D} = 0$, $\overline{RD} = 0$). This preselection remains valid until changed by a reset or a command.

Mode bit 7 is the master mask bit that disables all request inputs. It is used to disable all interrupts without modifying the IMR so that the previous IMR contents are valid when interrupts are re-enabled. When the master mask bit is low, it causes the EO line to remain disabled (low). Thus, for multiple-chip interrupt systems, one master mask bit can disable the whole interrupt structure. Alternatively, portions of the structure may be disabled. The state of the master mask bit is available as bit S3 of the Status register.

Programming

After reset, the Am9519 must be initialized by the CPU in order to perform useful work. At a minimum, the master mask bit and at least one of the IMR bits should be enabled. If vectoring is to be used, the response memory must be loaded; if not, the mode must be changed to a non-vectoring configuration. Normally, the first step will be to modify the Mode register and the Auto clear register in order to establish the configuration desired for the application. Then the response memory and byte count will be loaded for those request levels that will be in use. Finally, the master mask bit and at least portions of the IMR will be enabled to allow interrupt processing to proceed.

Commands

The host CPU configures, changes and inspects the internal condition of the Am9519 using the set of commands shown in Figure 4. An "X" entry in the table indicates a "don't care" state. All commands are entered by directly loading the Command register as shown in Figure 3 ($C/D = 1, \overline{WR} = 0$). Figure 5 shows the coding assignments for the Byte Count registers. A detailed description of each command is contained in the Am9519 Application Note AMPUB071.

NOTES:

- Typical values are for $T_A = 25^\circ\text{C}$, nominal supply voltage and nominal processing parameters.
- Test conditions assume transition times of 20ns or less, timing reference levels of 0.8V and 2.0V and output loading of one TTL gate plus 100pF, unless otherwise noted.
- Transition abbreviations used for the switching parameter symbols include: H = High, L = Low, V = Valid, X = unknown or don't care, Z = high impedance.
- Signal abbreviations used for the switching parameter symbols include: R = Read, W = Write, Q = Data Out, D = Data In, A = Address (CS and C/D), K = Interrupt Acknowledge, N = Enable Out, E = Enable In, P = Pause, C = RIP.
- Switching parameters are listed in alphabetical order.
- During the first IACK pulse, PAUSE will be low long enough to allow for priority resolution and will not go high until after RIP goes low (TCLPH).
- TKLQV applies only to second, third and fourth IACK pulses while RIP is low. During the first IACK pulse, Data Out will be valid following the falling edge of RIP (TCLQV).
- RIP is pulled low to indicate that an interrupt request has been selected. RIP cannot be pulled low until EI is high following an internal delay. TKLCL will govern the falling edge of RIP when EI is always high or is high early in the acknowledge cycle. TEHCL will govern when EI goes high later in the cycle. The rising edge of EI will be determined by the length of the preceding priority resolution chain. RIP remains low until after the rising edge of the IACK pulse that transfers the last response byte for the selected IREQ.
- Test conditions for the EI line assume timing reference levels of 0.8V and 2.0V with transition times of 10ns or less.
- Test conditions for the EO line assume output loading of two LS TTL gates plus 30pF and timing reference levels of 0.8V and 2.0V. Since EO normally only drives EI of another Am9519, higher speed operation can be specified with this more realistic test condition.
- The arrival of IACK will cause EO to go low, disabling additional circuits that may be connected to EO. If no valid interrupt is pending, EO will return high when EI is high. If a pending request is selected, EO will stay low until after the last IACK pulse for that interrupt is complete and RIP goes high.
- VOH specifications do not apply to RIP or GINT when active-low. These outputs are open-drain and VOH levels will be determined by external circuitry.

Am6012

12-Bit High-Speed Multiplying D/A Converter

Distinctive Characteristics

- All grades 12-bit monotonic over temperature
- Differential nonlinearity to $\pm .012\%$ (13 bits) max. over temperature
- Trimless design is inherently monotonic
- Fast settling output current: 250nsec
- Full scale current 4mA
- High output impedance and compliance: -5 to +10V
- Differential current outputs
- Low cost
- High-speed multiplying capability
- Direct interface to TTL, CMOS, ECL, HTL, NMOS
- Performance unchanged over supply range
- Low power consumption: 230mW
- R_{OUT} , C_{OUT} independent of logic code

GENERAL DESCRIPTION

The Am6012 series of 12-bit monolithic multiplying Digital to Analog Converters represent a new level of high speed and accuracy coupled with low cost. The Am6012 is the first 12-bit D/A Converter ever built using standard processing without the requirements of thin film resistors and/or active trimming of individual devices. The Am6012 uses sophisticated new circuit design concepts that give inherent monotonicity without requiring ultra precision internal components.

The Am6012 design guarantees a more uniform step size than is possible with standard binarily weighted DAC's. This $\pm 1/2$ LSB differential nonlinearity is desirable in many applications where local linearity is critical. The uniform step size allows finer resolution of levels and in most applications is more useful than conformance to an ideal straight line from zero to full scale.

The Am6012 has high voltage compliance, high impedance dual complementary outputs which increase its versatility and enable differential operation to effectively double the peak to peak output swing. These outputs can be used directly without op amps in many applications. The dual complementary outputs can also be connected in A/D converter applications to present a constant load current and significantly reduce switching transients and increase system throughput. Output full scale current is specified at 4mA, allowing use of smaller load resistors to minimize the output RC delay which usually dominates settling time at the 12-bit level.

The Am6012 series guarantees full 12-bit monotonicity for all grades and differential nonlinearity as tight as $\pm .012\%$ (13 bits) over the entire temperature range. Device performance is essentially independent of power supply voltage. The devices work over a wide operating range of +5, -12 volts to ± 18 volts.

ACCURACY SPECIFICATIONS

The design of the Am6012 emphasizes differential linearity which is a measure of the uniformity of each step in the transfer characteristic. The circuit design, described in greater detail on page 6, requires resistor matching and tracking tolerances of 8 times lower than that of previous designs to achieve and maintain monotonicity over temperature. This advantage has been used in the Am6012A to provide 13-bit differential nonlinearity over temperature, a level of performance not generally available in previous designs, even when using thin film resistors.

The figures illustrate that $\pm 1/2$ LSB (13-bit) differential nonlinearity guarantees a converter with 4096 distinct output levels. ± 1 LSB D.N.L. guarantees monotonicity, so that when the input code is increased the output will not decrease. Note that nonlinearity, or deviation from an ideal straight line through zero and full scale, cannot be visually determined from the figures. In most applications, 12-bit resolution and differential linearity are more important than linearity. This is especially true in video and graphics, where the human eye has difficulty discerning nonlinearity of less than 5%.

APPLICATION HINTS:

1. Reference current and reference resistor.

There is a 1 to 4 scale factor between the reference current (I_{REF}) and the full scale output current (I_{FS}). If $V_{REF} = +10V$ and $I_{FS} = 4mA$, the value of the R_{14} is:

$$R_{14} = \frac{4 \times 10 \text{ Vdft}}{4mA} = 10k\Omega \quad R_{14} = R_{15}$$

LIC-849

2. Reference amplifier compensation.

For AC reference applications, a minimum value compensation capacitor (C_C) is normally used. The value of this capacitor depends on the equivalent resistance at pin 14. The values to maximize bandwidth without oscillation are as follows:

**MINIMUM SIZE
COMPENSATION CAPACITOR
($I_{FS} = 4mA$, $I_{REF} = 1.0mA$)**

Reference Configuration	R_{14}	R_{15}	R_{IN}	C_C	I_{REF}
Positive Reference	V_{R+}	0V	N/C	.01 μ F	V_{R+}/R_{14}
Negative Reference	0V	V_{R-}	N/C	.01 μ F	$-V_{R-}/R_{14}$
Lo Impedance Bipolar Reference	V_{R+}	0V	V_{IN}	(Note 1)	$(V_{R+}/R_{14}) + (V_{IN}/R_{IN})$ (Note 2)
Hi Impedance Bipolar Reference	V_{R+}	V_{IN}	N/C	(Note 1)	$(V_{R+} - V_{IN})/R_{14}$ (Note 3)
Pulsed Reference (Note 4)	V_{R+}	0V	V_{IN}	No Cap	$(V_{R+}/R_{14}) + (V_{IN}/R_{IN})$

- Notes: 1. The compensation capacitor is a function of the impedance seen at the + V_{REF} input and must be at least $C = 5pF \times R_{14(eq)}$ in k Ω . For $R_{14} < 800\Omega$ no capacitor is necessary.
 2. For negative values of V_{IN} , V_{R+}/R_{14} must be greater than $-V_{IN} \text{ Max}/R_{IN}$ so that the amplifier is not turned off.
 3. For positive values of V_{IN} , V_{R+} must be greater than $V_{IN} \text{ Max}$ so the amplifier is not turned off.
 4. For pulsed operation, V_{R+} provides a DC offset and may be set to zero in some cases. The impedance at pin 14 should be 800 Ω or less.
 5. For optimum settling time, decouple $V-$ with 20 Ω and bypass with 22 μ F tantalum capacitor.

SEGMENTED DAC DESIGN INFORMATION

The design of a 12-bit D/A converter has traditionally required precision thin film resistors, a trimming method, and a binarily weighted ladder network. The Am6012 is a 12-bit DAC which uses diffused resistors and requires no trimming, cutting, blowing, or zapping to guarantee monotonicity for all grades over the temperature range. A proprietary design technique, departing from the traditional R-2R approach used in virtually all high speed high resolution converters, provides inherent monotonicity and differential linearity as high as 13 bits. This guarantees a more uniform step size over the temperature range than available trimmed 12-bit converters. The converter's performance is immune to variations in temperature, time, process, and mechanical stress. The circuit also features differential high compliance current outputs, wide supply range, and a multiplying reference input.

In most converter applications, uniform step size is more important than conformance to an ideal straight line. Most 12-bit converters are used for high resolution rather than high linearity, since few transducers are more linear than $\pm 0.1\%$. All classic binarily weighted converters require $\pm 1/2$ LSB ($\pm 0.12\%$) linearity in order to guarantee monotonicity, which requires very tight resistor matching and tracking. This new circuit uses conventional bipolar processing to achieve high differential linearity and monotonicity without requiring correspondingly high linearity, or conformance to an ideal straight line.

One design approach which provides monotonicity without requiring high linearity is the MOS switch-resistor string. This circuit is actually a full complement to a current switched R-2R DAC since it is slower, has a voltage output, and if implemented at the 12-bit level would use 4096 low tolerance resistors rather than a minimum number of high tolerance resistors as in the R-2R network. Its lack of speed and density for 12 bits are its drawbacks.

The technique used in the Am6012 combines the advantages of both the R-2R and 2^n R approaches. It is inherently monotonic, fast, and uses untrimmed resistors which are actually fewer in number than the classic R-2R ladder.

In order to properly describe the new design technique, the standard R-2R ladder approach used in previous 12-bit DAC's will first be discussed. Figure 1 shows the twelve-bit currents which are used in all possible binary combinations to generate 4096 analog output levels. The resistor ladder tolerance is most critical for the major carry, where the 11 least significant bits turn off and the most significant bit turns on. If the MSB is more than $1\mu\text{A}$ low, or -0.05% , the converter will be nonmonotonic. Table 1 shows the maximum tracking error which can be allowed over a 100°C range to maintain monotonicity, which is ± 1 LSB D.N.L. Achieving $\pm 1/2$ LSB differential nonlinearity is especially difficult since it requires a tracking temperature coefficient of ± 1.25 ppm/ $^\circ\text{C}$.

Figure 2 shows the transfer characteristic for the new technique, called the segmented DAC. The 4096 output levels are composed of 8 groups of 512 steps each. Each step group is gener-

ated by a 9-bit DAC, and each of the segment slopes is determined by one of 8 equal current sources, as shown in Figure 3. The resistors which determine monotonicity are in the 9-bit DAC. The major carry of the 9-bit DAC is repeated in each of the 8 segments, and requires eight times lower initial resistor accuracy and tracking to maintain a given differential nonlinearity over temperature.

The operation of the segmented DAC may be visualized by assuming an input code of all zeroes. The first segment current I_0 is divided into 512 levels by the 9-bit multiplying DAC and fed to the output, I_{OUT} . As the input code increases, a new segment current is selected for each 512 counts. The previous segment is fed to output I_{OUT} where the new step group is added to it, thus ensuring monotonicity independent of segment resistor values. All higher order segments feed I_{OUT} .

At each segment endpoint, monotonicity is assured because no critical resistor tolerances are involved. For example, at the midpoint of the transfer characteristic, as shown in Figure 2, $I_{4,0}$ is actually generated by the same segment resistor as $I_{3,511}$ and has been incremented by the remainder current of the 9-bit DAC.

In the segmented DAC, the precision of the 8 main resistors determines linearity only. The influence of each of these resistors on linearity is four times lower than that of the MSB resistor in an R-2R DAC. Hence, assuming the same resistor tolerances for both, the linearity of the segmented approach would actually be higher than that of an R-2R design.

The step generator or 9-bit DAC is composed of a master and a slave ladder. The slave ladder generates the four least significant bits from the remainder of the master ladder by active current splitting utilizing scaled emitters. This saves ladder resistors and greatly reduces the range of emitter scaling required in the 9-bit DAC. All current switches in the step generator are high speed fully differential switches which are capable of switching low currents at high speed. This allows the use of a binary scaled network all the way to the least significant bit which saves power and simplifies the circuitry.

Diffused resistors have advantages over thin film resistors beyond simple economy and bipolar process compatibility. The resistors are fabricated in single crystal rather than amorphous material which gives them better long term stability and tracking and much higher moisture resistance. They are diffused at 1000°C and so are resistant to changes in value due to thermal and chemical causes. Also, no burn-in is required for stability. The contact resistance between aluminum and silicon is more predictable than between aluminum and an amorphous thin film, and no sandwich metals are required to enhance or protect the contact or limit alloying. The initial match between two diffused resistors is similar to that of thin film since both are defined by photomasks and chemical etching. Since the resistors are not trimmed or altered after fabrication, their tracking and long term characteristics are not degraded.

Am6080

Microprocessor System Compatible 8-Bit High Speed Multiplying D/A Converter

DISTINCTIVE CHARACTERISTICS

- 8-Bit D/A with 8-Bit input data latch
- Compatible with most popular microprocessors including the AmZ8000 and the Am2900 Families
- Write, Chip Select and Data Enable logic on chip
- DAC appears as memory location to microprocessor
- MSB inversion under logic control
- Differential current output
- Choice of 6 coding formats
- Fast settling current output – 160ns
- Nonlinearity to $\pm 0.1\%$ max over temperature range
- Full scale current pre-matched to ± 1 LSB
- High output impedance and voltage compliance
- Low full scale current drift – $\pm 5\text{ppm}/^\circ\text{C}$
- Wide range multiplying capability – 2.0MHz bandwidth
- Direct interface to TTL, CMOS, NMOS
- High speed data latch – 80ns min write time

GENERAL DESCRIPTION

The Am6080 is a monolithic 8-bit multiplying Digital-to-Analog converter with an 8-bit data latch, chip select and other control signal lines which allow direct interface with microprocessor buses.

The converter allows a choice of 6 different coding formats. The most significant bit (D_7) can be inverted or non-inverted under the control of the code select input. The code control also provides a zero differential current output for 2's complement coding. A high voltage compliance, complementary current output pair is provided. The data latch is very high speed which makes the Am6080 capable of interfacing with high speed microprocessors.

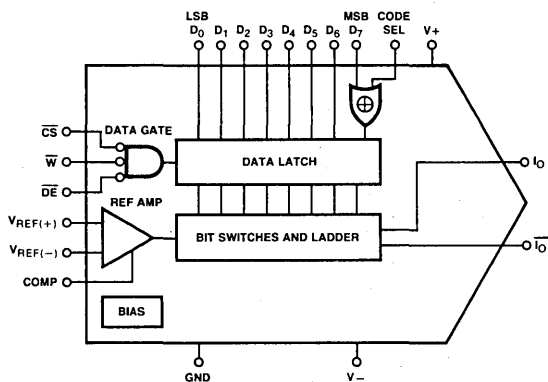

Monotonic multiplying performance is maintained over a more than 40 to 1 reference current range. Matching within ± 1 LSB

between reference and full scale current eliminates the need for full scale trimming in most applications.

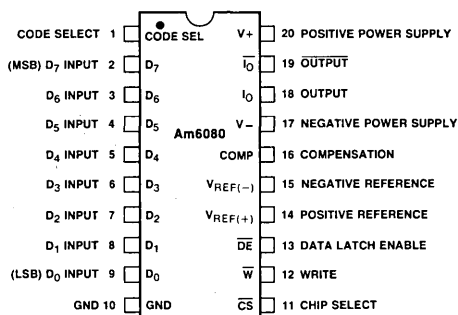

The Am6080 guarantees full 8-bit monotonicity. Nonlinearities as tight as 0.1% over the entire operating temperature range are available. Device performance is essentially unchanged over the full power supply voltage and temperature range.

Applications for the Am6080 include microprocessor compatible data acquisition systems and data distribution systems, 8-bit A/D converters, servo-motor and pen drivers, waveform generators, programmable attenuators, analog meter drivers, programmable power supplies, CRT display drivers and high speed modems.

- Output range selection with on chip multiplexer
- High speed data latch – 80ns min write time

GENERAL DESCRIPTION

The Am6081 is a monolithic 8-bit multiplying Digital-to-Analog converter with an 8-bit data latch, a 2-bit status latch, chip select and other control signal lines which allow direct interface with microprocessor buses.

The converter allows a choice of 8 different coding formats. The most significant bit (D_7) can be inverted or non-inverted under the control of the code select input. The code control also provides a zero differential current output for 2's complement coding. A pair of high voltage compliance, dual complementary current output channels is provided and is selected by the output status command. The output multiplexer also allows analog bus connection of several converters, range or output load selection, and time-shared operation between D/A and A/D functions. The data and status latches are high speed which makes the Am6081 capable of interfacing with high speed microprocessors. The DE and SE control signals allow the data and status latches to be updated

individually or simultaneously.

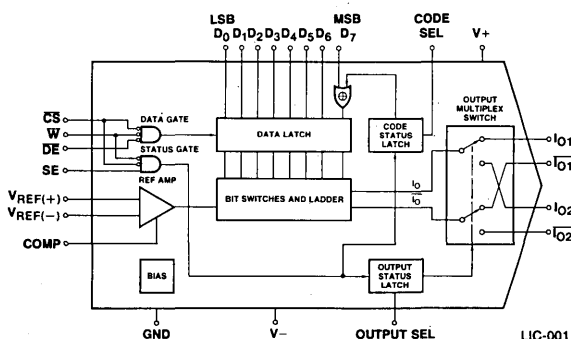

Monotonic multiplying performance is maintained over a more than 40 to 1 reference current range. Matching within ± 1 LSB between reference and full scale current eliminates the need for full scale trimming in most applications.

The Am6081 guarantees full 8-bit monotonicity. Nonlinearities as tight as 0.1% over the entire operating temperature range are available. Device performance is essentially unchanged over the full power supply voltage and temperature range.

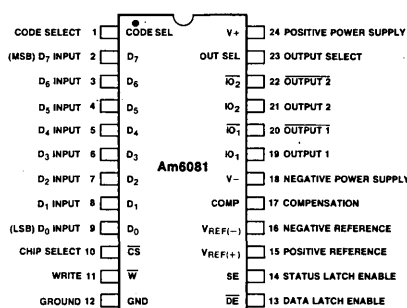

Applications for the Am6081 include microprocessor compatible data acquisition systems and data distribution systems, 8-bit A/D converters, servo-motor and pen drivers, waveform generators, programmable attenuators, analog meter drivers, programmable power supplies, CRT display drivers and high speed modems.

LIC-002

Am6081 FUNCTIONAL PIN DESCRIPTION

Symbol Function

- \overline{CS}** Chip Select – This active low input signal enables the Am6081. Writing into the data or status latches occurs only when the device is selected.
- \overline{DE}** Data Latch Enable – This active low input is used to enable the data latch. The \overline{CS} , \overline{DE} , and \overline{W} must be active in order to write into the data latch.
- SE** Status Latch Enable – This active high input is used to enable the status latches. The \overline{CS} , SE, and \overline{W} must be active in order to write into the status latches.
- \overline{W}** Write – This active low control signal enables the data and status latches when the \overline{CS} , \overline{DE} , and SE inputs are active.
- D₀-D₇** D₀-D₇ are the input bits 1-8 to the input data latch. Data is transferred to the data latch when \overline{CS} , \overline{DE} , and \overline{W} are active and is latched when any of the enable signals go inactive.

- CODE SEL** Code Select – Input to the CODE SEL latch. The latch is transparent when \overline{CS} , SE and \overline{W} are active and is latched when any of the above signals go inactive. When CODE SEL latch = 0, the MSB (D₇) is inverted and 1 LSB balance current is added to the $\overline{I_0}$ output.
- OUT SEL** Output Select – Input to the OUT SEL latch. The latch is transparent when \overline{CS} , SE and \overline{W} are active and is latched when any of the above signals go inactive. When the OUT SEL latch is low, the channel 1 output pair (I_{O1} , $\overline{I_{O1}}$) is selected. When the OUT SEL latch is high, the channel 2 output pair (I_{O2} , $\overline{I_{O2}}$) is selected.
- V_{REF(+)}** Positive and negative reference voltage to the reference bias amplifier. These differential inputs allow the use of positive, negative and bipolar references.
- V_{REF(-)}**
- COMP** Compensation – Frequency compensating terminal for the reference amplifier.
- I_{O1}, $\overline{I_{O1}}$** These high impedance current output pairs are selected by the output select latch. I_{O1} and I_{O2} are true outputs and $\overline{I_{O1}}$ and $\overline{I_{O2}}$ are complementary outputs.
- I_{O2}, $\overline{I_{O2}}$**

Am6108

Microprocessor System Compatible 8-Bit A/D Converter

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

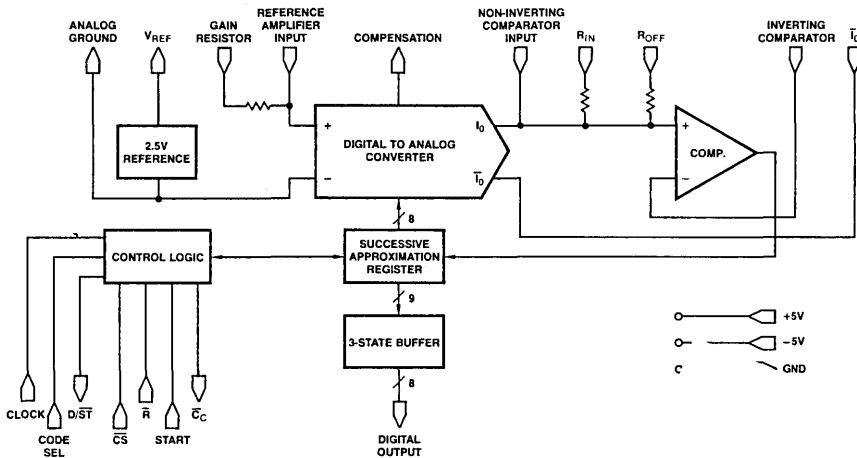

- 1 μ s conversion time
- Trimmed internal voltage reference
- 0.1% nonlinearity
- Ratiometric operation
- Low operating voltages
- Internal matched gain reference and offset resistors
- Microprocessor compatible
- 3-state outputs
- Pin-programmable unipolar or bipolar two's complement conversion
- Conversion complete available as interrupt or as multiplexed output on data bus

GENERAL DESCRIPTION

The Am6108 is a microprocessor compatible 8-bit high-speed analog-to-digital converter. The Am6108 is the first fully monolithic high-speed A/D to include a precision reference, DAC, comparator, SAR, scale resistors, output 3-state buffers and control logic. The Am6108 is capable of completing an 8-bit conversion in under one microsecond and can handle input voltage ranges of 0 to 10V, 0 to 5V, and ± 5 V without external components. With appropriate external resistors, the user can program the device to operate on other input signal ranges (2 or 3 precision resistors are required). Full 8-bit performance is guaranteed over temperature. The device has 3-state outputs for bus compatibility and two status outputs – one a standard TTL signal and the other available as a status output on the data bus.

The Am6108 is useful in microprocessor-based systems, or can be used in a stand-alone mode. The conversion time is short enough to allow most microprocessors to accept data immediately after requesting a conversion. Applications include Analog I/O subsystems and servomechanism control.

AMD ROM Flow

Key Points

1. Be sure to specify all Chip Selects.
2. Be sure to specify device marking.
3. Be sure that the format for the input data is included with the data.
4. Delivery times for both prototypes and production units are dependent on the turnaround time required by the customer for verification.

1 Week after receipt of customer data, a printout in Hexadecimal and/or AMD Hexadecimal IBM cards will be sent for customer verification.

4 Weeks after verification of the printouts, 10 prototypes per code are shipped to the customer for verification.

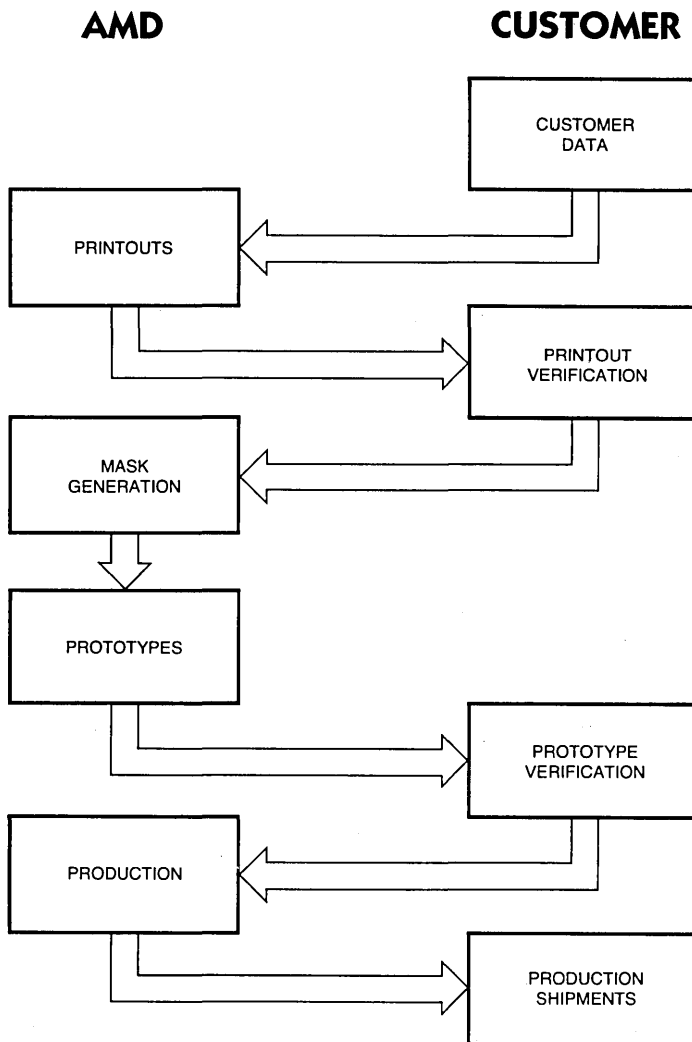

6 Weeks after verification of prototypes, production quantities (up to 1000 pcs. per code) can be shipped.

Preferred Data Format:

AMD HEXADECIMAL

Acceptable Formats:

- E-PROMs (2708/2716)
- Intel Hexadecimal
- Intel BPNF
- E-A Octal
- G.I. Binary
- Motorola Hexadecimal
- T.I. Octal

AMD Preferred Format

PROGRAMMING INSTRUCTIONS

Custom Pattern Ordering Information

The Am9208/Am9216/Am9217/C8316A/
Am9218/C8316E/Am9232/Am9233 are programmed from
punched cards, card coding forms or from paper tape in card

image form in the format as shown below.
Logic "1" = a more positive voltage (normally +5.0V)
Logic "0" = a more negative voltage (normally 0V)

FIRST CARD

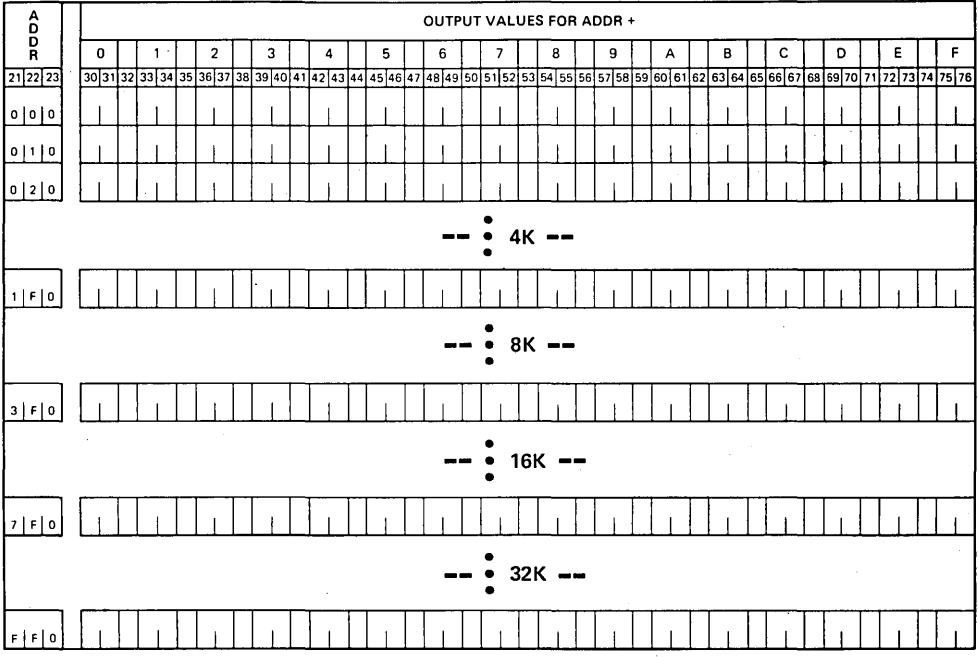

Column Number	Description
10 through 29	Customer Name
32 through 37	Total number of "1"s contained in the data. This is optional and should be left blank if not used.
50 through 62	9208B, 9208C, 9208D, 9216B, 9216C, 8316A, 9217A, 9217B, 8316E, 9218B 9218C, 9232B, 9232C, 9233B or 9233C
65 through 72	Data.

SECOND CARD

Column Number	Description
29	CS ₃ input required to select chip (0 or 1) only for 9217, 8316A, 9218, 8316E
31	CS ₂ input required to select chip (0 or 1)
33	CS ₁ input required to select chip (0 or 1)
35	CS ₀ input required to select chip (0 or 1) only for 9214

The Hexadecimal Option is a compact way of presenting the data. This format requires only 32/64/128/256 data cards. Each data card contains the 8-bit output information for 16 storage locations in the memory. The address indicated in columns 21, 22 and 23 is the address of the data presented in columns 30 and 31. Addresses for successive data are assumed to be in incremental ascending order from the initial address. Since

the address in columns 21, 22 and 23 indexes the first data on the card, column 23 is always a zero. Columns 21 and 22 take all hex values from 00 through 1F/3F/7F/FF cards in all. Data is entered in hex values and may be any combination of 8 bits, that is, hex values from 00 through FF.

Am9016

16,384 x 1 Dynamic R/W Random Access Memory

DISTINCTIVE CHARACTERISTICS

- High density 16k x 1 organization
- Direct replacement for MK4116
- Low maximum power dissipation – 462mW active, 20mW standby
- High speed operation – 150ns access, 320ns cycle
- $\pm 10\%$ tolerance on standard +12, +5, -5 voltages
- TTL compatible interface signals
- Three-state output
- RAS only, RMW and Page mode clocking options
- 128 cycle refreshing
- Unlatched data output
- Standard 16-pin, .3 inch wide dual in-line package
- Double poly N-channel silicon gate MOS technology
- 100% MIL-STD-883 reliability assurance testing

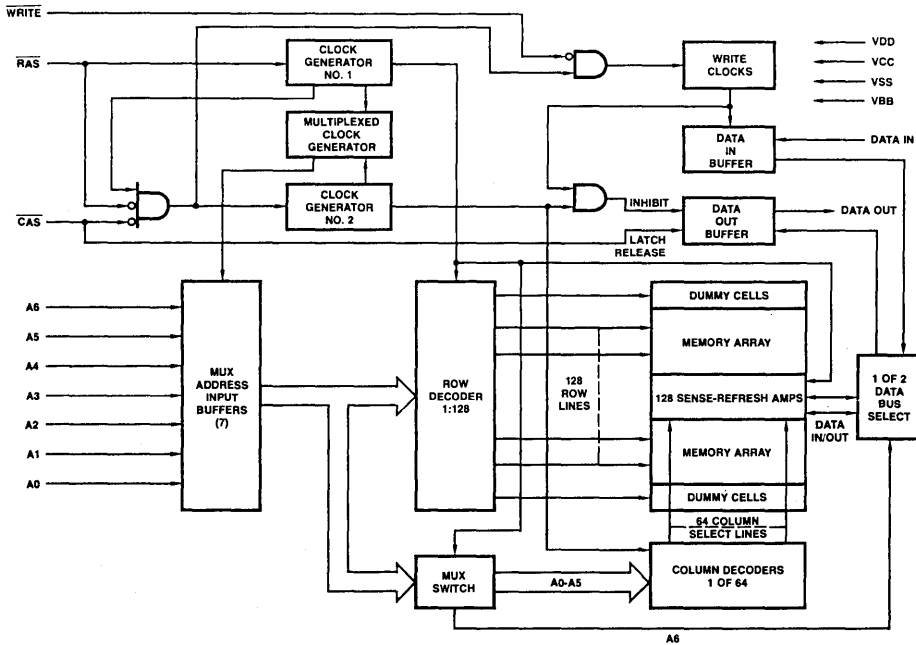

GENERAL DESCRIPTION

The Am9016 is a high speed, 16k-bit, dynamic, read/write random access memory. It is organized as 16,384 words by 1 bit per word and is packaged in a standard 16-pin DIP. The basic memory element is a single transistor cell that stores charge on a small capacitor. This mechanism requires periodic refreshing of the memory cells to maintain stored information.

All input signals, including the two clocks, are TTL compatible. The Row Address Stroba (RAS) loads the row address and the Column Address Stroba (CAS) loads the column address. The row and column address signals share 7 input lines. Active cycles are initiated when $\overline{\text{RAS}}$ goes low, and standby mode is entered when $\overline{\text{RAS}}$ goes high. In addition to normal read and write cycles, other types of operations are available to improve versatility, performance, and power dissipation.

The three-state output buffer turns on when the column access time has elapsed and turns off after CAS goes high. Input and output data are the same polarity.

MOS-191

MAXIMUM RATINGS beyond which useful life may be impaired

Storage Temperature	-65°C to +150°C
Ambient Temperature Under Bias	0°C to +70°C
Voltage on Any Pin Relative to VBB	-0.5V to +20V
VDD and VCC Supply Voltages with Respect to VSS	-1.0V to +15.0V
VBB – VSS (VDD – VSS > 0V)	0V
Power Dissipation	1.0W
Short Circuit Output Current	50mA

The products described by this specification include internal circuitry designed to protect input devices from damaging accumulation of static charge. It is suggested nevertheless, that conventional precautions be observed during storage, handling, and use in order to avoid exposure to excessive voltages.

NOTES

- Typical values are for $T_A = 25^\circ\text{C}$, nominal supply voltages and nominal processing parameters.
- Signal transition times are assumed to be 5ns. Transition times are measured between specified high and low logic levels.
- Timing reference levels for both input and output signals are the specified worst-case logic levels.
- VCC is used in the output buffer only. ICC will therefore depend only on leakage current and output loading. When the output is ON and at a logic high level, VCC is connected to the Data Out pin through an equivalent resistance of approximately 135 Ω . In standby mode VCC may be reduced to zero without affecting stored data or refresh operations.
- Output loading is two standard TTL loads plus 100pF capacitance.
- Both RAS and CAS must be low to read data. Access timing will depend on the relative positions of their falling edges. When tRCD is less than the maximum value shown, access time depends on RAS and tRAC governs. When tRCD is more than the maximum value shown access time depends on CAS and tCAC governs. The

maximum value listed for tRCD is shown for reference purposes only and does not restrict operation of the part.

- Timing reference points for data input set-up and hold times will depend on what type of write cycle is being performed and will be the later falling edge of CAS or WE.
- At least eight initialization cycles that exercise RAS should be performed after power-up and before valid operations are begun.
- The tWCS, tRWD and tCWD parameters are shown for reference purposes only and do not restrict the operating flexibility of the part. When the falling edge of WE follows the falling edge of CAS by at most tWCS, the data output buffer will remain off for the whole cycle and an "early write" cycle is defined. When the falling edge of WE follows the falling edges of RAS and CAS by at least tRWD and tCWD respectively, the Data Out from the addressed cell will be valid at the access time and a "read/write" cycle is defined. The falling edge of WE may also occur at intermediate positions, but the condition and validity of the Data Out signal will not be known.
- Switching characteristics are listed in alphabetical order.
- All voltages referenced to VSS.

APPLICATION INFORMATION

The Am9016 electrical connections are such that if power is applied with the device installed upside down it will be permanently damaged. Precautions should be taken to avoid this mishap.

OPERATING CYCLES

Random read operations from any location hold the \overline{WE} line high and follow this sequence of events:

- 1) The row address is applied to the address inputs and \overline{RAS} is switched low.
- 2) After the row address hold time has elapsed, the column address is applied to the address inputs and \overline{CAS} is switched low.
- 3) Following the access time, the output will turn on and valid read data will be present. The data will remain valid as long as \overline{CAS} is low.
- 4) \overline{CAS} and \overline{RAS} are then switched high to end the operation. A new cycle cannot begin until the precharge period has elapsed.

Random write operations follow the same sequence of events, except that the \overline{WE} line is low for some portion of the cycle. If the data to be written is available early in the cycle, it will usually be convenient to simply have \overline{WE} low for the whole write operation.

Sequential Read and Write operations at the same location can be designed to save time because re-addressing is not necessary. A read/write cycle holds \overline{WE} high until a valid read is established and then strobes new data in with the falling edge of \overline{WE} .

After the power is first applied to the device, the internal circuit requires execution of at least eight initialization cycles which exercise \overline{RAS} before valid memory accesses are begun.

ADDRESSING

14 address bits are required to select one location out of the 16,384 cells in the memory. Two groups of 7 bits each are multiplexed onto the 7 address lines and latched into the internal address registers. Two negative-going external clocks are used to control the multiplexing. The Row Address Strobe (\overline{RAS}) enters the row address bits and the Column Address Strobe (\overline{CAS}) enters the column address bits.

When \overline{RAS} is inactive, the memory enters its low power standby mode. Once the row address has been latched, it need not be changed for successive operations within the same row, allowing high-speed page-mode operations.

Page-mode operations first establish the row address and then maintain \overline{RAS} low while \overline{CAS} is repetitively cycled and designated operations are performed. Any column address within the selected row may be accessed in any sequence. The maximum time that \overline{RAS} can remain low is the factor limiting the number of page-mode operations that can be performed.

Multiplexed addressing does not introduce extra delays in the access path. By inserting the row address first and the column address second, the memory takes advantage of the fact that the delay path through the memory is shorter for column addresses. The column address does not propagate through the cell matrix as the row address does and it can therefore arrive somewhat later than the row address without impacting the access time.

REFRESH

The Am9016 is a dynamic memory and each cell must be refreshed at least once every refresh interval in order to maintain the cell contents. Any operation that accesses a row serves to refresh all 128 cells in the row. Thus the refresh requirement is met by accessing all 128 rows at least once every refresh interval. This may be accomplished, in some applications, in the course of performing normal operations. Alternatively, special refresh operations may be initiated. These special operations could be simply additional conventional accesses or they could be " \overline{RAS} -only" cycles. Since only the rows need to be addressed, \overline{CAS} may be held high while \overline{RAS} is cycled and the appropriate row addresses are input. Power required for refreshing is minimized and simplified control circuitry will often be possible.

DATA INPUT/OUTPUT

Data is written into a selected cell by the combination of \overline{WE} and \overline{CAS} while \overline{RAS} is low. The later negative transition of \overline{WE} or \overline{CAS} strobes the data into the internal register. In a write cycle, if the \overline{WE} input is brought low prior to \overline{CAS} , the data is strobed by \overline{CAS} , and the set-up and hold times are referenced to \overline{CAS} . If the cycle is a read/write cycle then the data set-up and hold times are referenced to the negative edge of \overline{WE} .

In the read cycle the data is read by maintaining \overline{WE} in the high state throughout the portion of the memory cycle in which \overline{CAS} is low. The selected valid data will appear at the output within the specified access time.

DATA OUTPUT CONTROL

Any time \overline{CAS} is high the data output will be off. The output contains either one or zero during read cycle after the access time has elapsed. Data remains valid from the access time until \overline{CAS} is returned to the high state. The output data is the same polarity as the input data.

The user can control the output state during write operations by controlling the placement of the \overline{WE} signal. In the "early write" cycle (see note 9) the output is at a high impedance state throughout the entire cycle.

POWER CONSIDERATIONS

\overline{RAS} and/or \overline{CAS} can be decoded and used as a chip select signal for the Am9016 but overall system power is minimized if \overline{RAS} is used for this purpose. The devices which do not receive \overline{RAS} will be in low power standby mode regardless of the state of \overline{CAS} .

At all times the Absolute Maximum Rating Conditions must be observed. During power supply sequencing VBB should never be more positive than VSS when power is applied to VDD.

4096 x 1 Static R/W Random Access Memory

DISTINCTIVE CHARACTERISTICS

- **LOW OPERATING POWER (MAX)**
Am9044/Am9244 385mW (70mA)
Am90L44/Am92L44 275mW (50mA)
- **LOW STANDBY POWER (MAX)**
Am92L44 110mW (20mA)
- Access times down to 200ns (max)
- Military temperature range available to 250ns (max)
- Am9044 is a direct plug-in replacement for 4044
- Am9244 pin and function compatible with Am9044 and 4044 plus \overline{CS} power down feature
- Fully static – no clocking
- Identical access and cycle time
- High output drive –
 4.0mA sink current @ 0.4V
- TTL identical interface logic levels
- 100% MIL-STD-883 reliability assurance testing

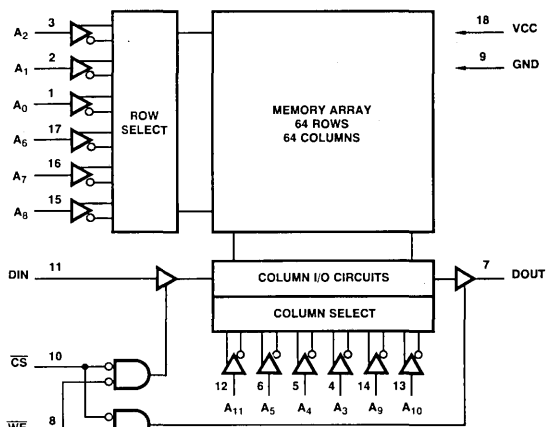

GENERAL DESCRIPTION

The Am9044 and Am9244 are high performance, static, N-Channel, read/write, random access memories organized as 4096 x 1. Operation is from a single 5V supply, and all input/output levels are identical to standard TTL specifications. Low power versions of both devices are available with power savings of about 30%. The Am9044 and Am9244 are the same except that the Am9244 offers an automatic \overline{CS} power down feature.

The Am9244 remains in a low power standby mode as long as \overline{CS} remains high, thus reducing its power requirements. The Am9244 power decreases from 385mW to 165mW in the standby mode, and the Am92L44 from 275mW to 110mW. The \overline{CS} input does not affect the power dissipation of the Am9044.

Data readout is not destructive and the same polarity as data input. \overline{CS} provides for easy selection of an individual package when the outputs are OR-tied. The outputs of 4.0mA for Am9244 and Am9044 provide increased short circuit current for improved capacitive drive.

ELECTRICAL CHARACTERISTICS over operating range

Parameter	Description	Test Conditions	Am92L44		Am9244		Am90L44		Am9044		Units	
			Typ.	Max.	Typ.	Max.	Typ.	Max.	Typ.	Max.		
ICC	VCC Operating Supply Current	Max. VCC $\overline{\text{CS}} \leq$ VIL for Am9244/92L44	TA = 0°C		50		70		50		70	mA
			TA = -55°C		60		80		60		80	
IPD	Automatic $\overline{\text{CS}}$ Power Down Current	Max. VCC (CS \geq VIH)	TA = 0°C		20		30		-		-	mA
			TA = -55°C		22		33		-		-	

Notes:

- Typical values are for TA = 25°C, nominal supply voltage and nominal processing parameters.
- For test purposes, not more than one output at a time should be shorted. Short circuit test duration should not exceed 30 seconds.
- Test conditions assume signal transition times of 10ns or less, timing reference levels of 1.5V and output loading of one standard TTL gate plus 100pF.

- The internal write time of the memory is defined by the overlap of CS low and WE low. Both signals must be low to initiate a write and either signal can terminate a write by going high. The data input setup and hold timing should be referenced to the rising edge of the signal that terminates the write.
- Chip Select access time (tCO) is longer for the Am9244 than for the Am9044. The specified address access time will be valid only when Chip Select is low soon enough for tCO to elapse.

GENERAL DESCRIPTION

The Am9114 and Am9124 are high performance, static, N-Channel, read/write, random access memories organized as 1024 x 4. Operation is from a single 5V supply, and all input/output levels are identical to standard TTL specifications. Low power versions of both devices are available with power savings of over 30%. The Am9114 and Am9124 are the same except that the Am9124 offers an automatic \overline{CS} power down feature.

The Am9124 remains in a low power standby mode as long as \overline{CS} remains high, thus reducing its power requirements. The Am9124 power decreases from 368mW to 158mW in the standby mode, and the Am91L24 from 262mW to 105mW. The \overline{CS} input does not affect the power dissipation of the Am9114. (See Figure 1, page 4).

Data readout is non-destructive and the same polarity as data input. \overline{CS} provides for easy selection of an individual package when the outputs are OR-tied. The outputs of 4.0mA for Am9124 and 3.2mA for Am9114 provides increased short circuit current for improved capacitive drive.

Am2716

2048 x 8-Bit UV Erasable PROM

DISTINCTIVE CHARACTERISTICS

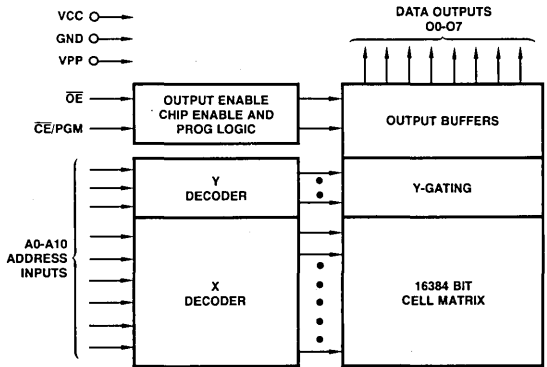

- Direct replacement for Intel 2716
- Interchangeable with Am9218 – 16K ROM
- Single +5V power supply
- Fast access time – 450ns
- Low power dissipation
 - 525mW active
 - 132mW standby
- Fully static operation – no clocks
- Three-state outputs
- TTL compatible inputs/outputs
- 100% MIL-STD-883 reliability assurance testing

GENERAL DESCRIPTION

The Am2716 is a 16384-bit ultraviolet erasable and programmable read-only memory. It is organized as 2048 words by 8 bits per word, operates from a single +5V supply, has a static standby mode, and features fast single address location programming.

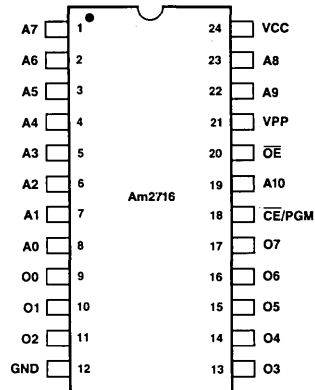

Because the Am2716 operates from a single +5V supply, it is ideal for use in microprocessor systems. All programming signals are TTL levels, requiring a single pulse. For programming outside of the system, existing EPROM programmers may be used. Locations may be programmed singly, in blocks, or at random. Total programming time for all bits is 100 seconds.

CAPACITANCE (Note 3)

T_A = +25°C, f = 1MHz

Parameters	Description	Test Conditions	Typ	Max	Units
CIN	Input Capacitance	V _{IN} = 0V	4	6	pF
COU	Output Capacitance	V _{OUT} = 0V	8	12	pF

- Notes: 1. VCC must be applied simultaneously or before VPP and removed simultaneously or after VPP.
 2. VPP may be connected directly to VCC except during programming. The supply current would then be the sum of ICC and IPP1.
 3. This parameter is only sampled and is not 100% tested.

AC WAVEFORMS (Note 1)

MOS-201

- Notes: 1. V_{CC} must be applied simultaneously or before V_{PP} and removed simultaneously or after V_{PP} .
 2. \overline{OE} may be delayed up to $t_{ACC} - t_{OE}$ after the falling edge of \overline{CE} without impact on t_{ACC} .
 3. t_{DF} is specified from \overline{OE} or \overline{CE} , whichever occurs first.

PROGRAM OPERATION

DC PROGRAMMING CHARACTERISTICS

T_A = +25°C ±5°C, VCC (Note 1) = 5V ±5%, VPP (Notes 1, 2) = 25V ±1V

Parameters	Description	Test Conditions	Min	Max	Units
ILI	Input Current	V _{IN} = 5.25V/0.45V		10	μA
IPP1	VPP Supply Current	$\overline{CE}/PGM = VIL$		5	mA
IPP2	VPP Supply Current During Programming Pulse	$\overline{CE}/PGM = VIH$		30	mA
ICC	VCC Supply Current			100	mA
VIL	Input Low Level		-0.1	0.8	Volts
VIH	Input High Level		2.0	VCC+1	Volts

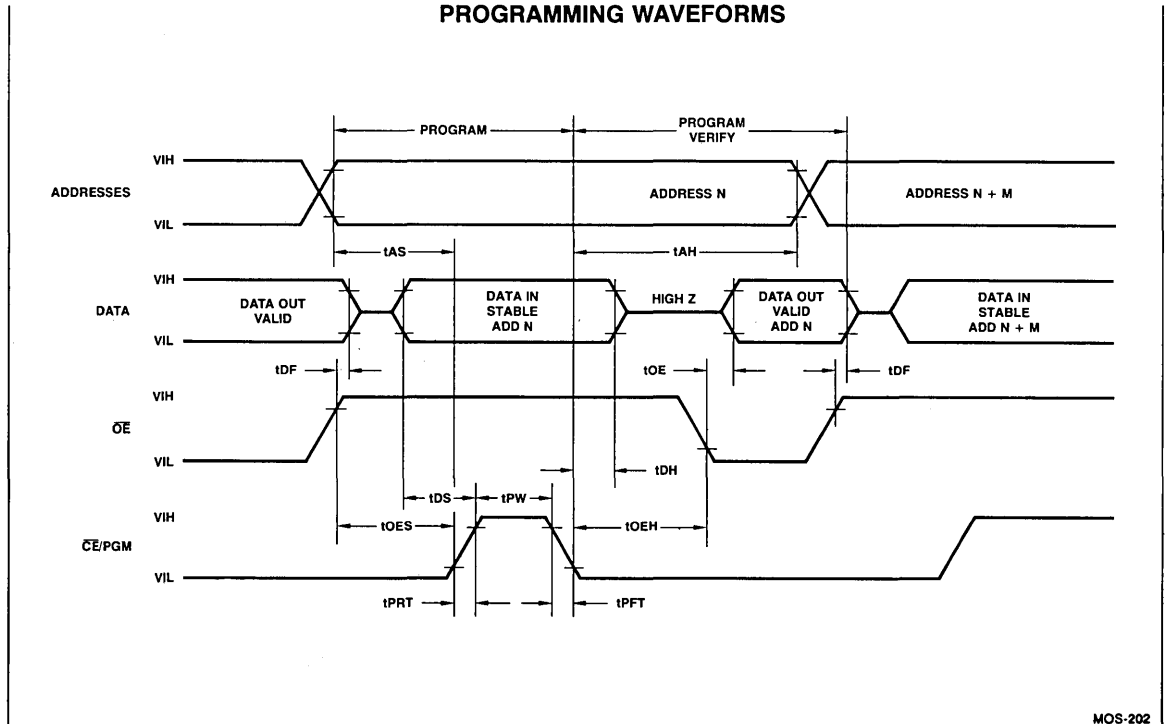

- Notes: 1. VCC must be applied simultaneously or before VPP and removed simultaneously or after VPP.
 2. VPP must not be greater than 26 volts including overshoot. Permanent device damage may occur if the device is taken out of or put into the socket when VPP = 25 volts is applied. Also, during $\overline{OE} = \overline{CE}/PGM = VIH$, VPP must not be switched from 5 volts to 25 volts or vice versa.

AC PROGRAMMING CHARACTERISTICS

T_A = +25°C ±5°C, VCC (Note 1) = 5V ±5%, VPP (Notes 1, 2) = 25V ±1V

Parameters	Description	Test Conditions	Min	Max	Units
tAS	Address Set-up Time	Input tR and tF (10% to 90%) = 20ns Input Signal Levels = 0.8V to 2.2V Input Timing Reference Level = 1V and 2V Output Timing Reference Level = 0.8V and 2V	2		μS
tOES	Output Enable Set-up Time		2		μS
tDS	Data Set-up Time		2		μS
tAH	Address Hold Time		2		μS
tOEH	Output Enable Hold Time		2		μS
tDH	Data Hold Time		2		μS
tDF	Output Disable to Output Float Delay ($\overline{CE}/PGM = VIL$)		0	120	ns
tOE	Output Enable to Output Delay ($\overline{CE}/PGM = VIL$)		-	120	ns
tPW	Program Pulse Width		45	55	ms
tPRT	Program Pulse Rise Time		5	-	ns
tPFT	Program Pulse Fall Time		5	-	ns

PROGRAMMING WAVEFORMS

ERASING THE Am2716

In order to clear all locations of their programmed contents, it is necessary to expose the Am2716 to an ultraviolet light source. A dosage of 15 Wseconds/cm² is required to completely erase an Am2716. This dosage can be obtained by exposure to an ultraviolet lamp [(wavelength of 2537 Angstroms (Å))] with intensity of 12000 μW/cm² for 15 to 20 minutes. The Am2716 should be about one inch from the source and all filters should be removed from the UV light source prior to erasure.

It is important to note that the Am2716, and similar devices, will erase with light sources having wavelengths shorter than 4000 Angstroms. Although erasure times will be much longer than with UV sources at 2537 Å, nevertheless the exposure to fluorescent light and sunlight will eventually erase the Am2716, and exposure to them should be prevented to realize maximum system reliability. If used in such an environment, the package windows should be covered by an opaque label or substance.

PROGRAMMING THE Am2716

Upon delivery, or after each erasure the Am2716 has all 16384 bits in the "1", or high state. "0s" are loaded into the Am2716 through the procedure of programming.

The programming mode is entered when +25V is applied to the VPP pin and when \overline{OE} is at VIH. The address to be programmed is applied to the proper address pins. 8-bit patterns are placed on the respective data output pins. The voltage levels should be standard TTL levels. When both the address and data are stable, a 50msec, TTL high level pulse is applied to the \overline{CE}/PGM input to accomplish the programming.

The procedure can be done manually, address by address, randomly, or automatically via the proper circuitry. All that is required is that one 50msec program pulse be applied at each address to be programmed. It is necessary that this program pulse width not exceed 55msec. Therefore, applying a DC level to the \overline{CE}/PGM input is prohibited when programming.

READ MODE

The Am2716 has two control functions, both of which must be logically satisfied in order to obtain data at the outputs. Chip Enable (\overline{CE}) is the power control and should be used for device

selection. Output Enable (\overline{OE}) is the output control and should be used to gate data to the output pins, independent of device selection. Assuming that addresses are stable, address access time (tACC) is equal to the delay from \overline{CE} to output (tCE). Data is available at the outputs 120ns (tOE) after the falling edge of \overline{OE} , assuming that \overline{CE} has been low and addresses have been stable for at least tACC - tOE.

STANDBY MODE

The Am2716 has a standby mode which reduces the active power dissipation by 75%, from 525mW to 132mW. The Am2716 is placed in the standby mode by applying a TTL high signal to the \overline{CE} input. When in standby mode, the outputs are in a high impedance state, independent of the \overline{OE} input.

OUTPUT OR-TIEING

To accommodate multiple memory connections, a 2-line control function is provided to allow for:

1. Low memory power dissipation
2. Assurance that output bus contention will not occur.

It is recommended that \overline{CE} be decoded and used as the primary device selecting function, while \overline{OE} be made a common connection to all devices in the array and connected to the READ line from the system control bus. This assures that all deselected memory devices are in their low-power standby mode and that the output pins are only active when data is desired from a particular memory device.

PROGRAM INHIBIT

Programming of multiple Am2716s in parallel with different data is also easily accomplished. Except for \overline{CE}/PGM , all like inputs (including \overline{OE}) of the parallel Am2716s may be common. A TTL level program pulse applied to an Am2716's \overline{CE}/PGM input with VPP at 25V will program that Am2716. A low level \overline{CE}/PGM input inhibits the other Am2716 from being programmed.

PROGRAM VERIFY

A verify should be performed on the programmed bits to determine that they were correctly programmed. The verify may be performed with VPP at 25V. Except during programming and program verify, VPP must be at 5V.

Am9218/8316E

2048 x 8 Read Only Memory

DISTINCTIVE CHARACTERISTICS

- 2048 x 8 organization
- Plug-in replacement for 8316E
- Access times as fast as 350 ns
- Fully capacitive inputs — simplified driving
- 3 fully programmable Chip Selects — increased flexibility
- Logic voltage levels compatible with TTL
- Three-state output buffers — simplified expansion
- Drives two full TTL loads
- Single supply voltage — +5.0V
- Low power dissipation
- N-channel silicon gate MOS technology
- 100% MIL-STD-883 reliability assurance testing

FUNCTIONAL DESCRIPTION

The Am9218 devices are high performance, 16384-bit, static, mask programmed, read only memories. Each memory is implemented as 2048 words by 8 bits per word. This organization simplifies the design of small memory systems and permits incremental memory sizes as small as 2048 words. The fast access times provided allow the ROM to service high performance microcomputer applications without stalling the processor.

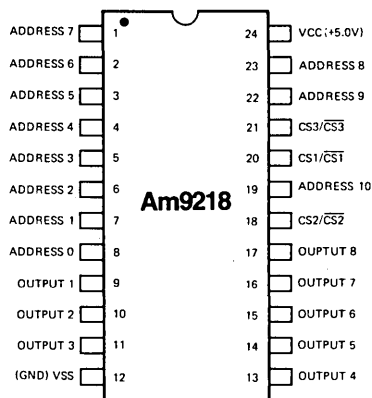

Three programmable Chip Select input signals are provided to control the output buffers. Each Chip Select polarity may be specified by the customer thus allowing the addressing of 8 memory chips without external gating. The outputs of unselected chips are turned off and assume a high impedance state. This permits wire-ORing with additional Am9218 devices and other three-state components.

These memories are fully static and require no clock signals of any kind. A selected chip will output data from a location specified by whatever address is present on the address input lines. Input and output voltage levels are compatible with TTL specifications.

PROGRAMMING INSTRUCTIONS
CUSTOM PATTERN ORDERING INFORMATION

The Am9218 is programmed from punched cards, card coding forms or paper tape in card image format as shown below.
 Logic "1" = a more positive voltage (normally +5.0 V)
 Logic "0" = a more negative voltage (normally 0 V)

FIRST CARD

Column Number	Description
10 thru 29	Customer Name
32 thru 37	Total number of "1's" contained in the data. This is optional and should be left blank if not used.
50 thru 62	8316E or 9218
65 thru 72	Optional information

SECOND CARD

Column Number	Description
29	CS3 input required to select chip (0 or 1)
31	CS2 input required to select chip (0 or 1)
33	CS1 input required to select chip (0 or 1)

Two options are provided for entering the data pattern with the remaining cards.

OPTION 1 is the Binary Option where the address and data are presented in binary form on the basis of one word per card. With this option 2048 data cards are required.

Column Number	Description
10, 12, 14, 16, 18	Address input pattern with the most significant bit (A10) in column 10 and the least significant bit (A0) in column 30.
20, 22, 24, 26, 28, 30	
40, 42, 44, 46, 48, 50, 52, 54	Output pattern with the most significant bit (O8) in column 40 and the least significant bit (O1) in column 54.
73 thru 80	Coding these columns is not essential and may be used for card identification purposes.

OPTION 2 is the Hexadecimal Option and is a much more compact way of presenting the data. This format requires only 128 data cards. Each data card contains the 8-bit output information for 16 storage locations in the memory. The address indicated in columns 21, 22 and 23 is the address of the data presented in columns 30 and 31. Addresses for successive data are assumed to be in incremental ascending order from the initial address. Since the address in columns 21, 22 and 23 always points only to the first data on the card, column 23 is always zero. Columns 21 and 22 take all hex values from 00 through 7F: 128 cards in all. Data is entered in hex values and may be any combination of 8 bits, that is, hex values from 00 through FF.

4096 X 8 Read Only Memory

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

- 4096 X 8 organization
- No clocks or refresh required
- Access time selected to 300ns
- Fully capacitive inputs – simplified driving
- 2 mask programmable chip selects – increased flexibility
- Logic voltage levels compatible with TTL
- Three state output buffers – simplified expansion
- Drives two TTL loads
- Single +5 volt power supply
- Two different pinouts for universal application
- Low power dissipation
- 100% MIL-STD-883 reliability assurance testing
- Non-connect option on chip selects.

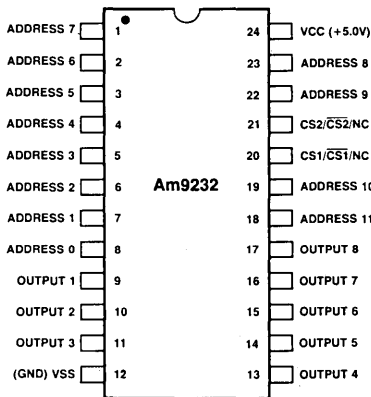

FUNCTIONAL DESCRIPTION

The Am9232/33 devices are high performance, 32,768-bit, static, mask programmed, read only memories. Each memory is implemented as 4096 words by 8 bits per word. This organization simplifies the design of small memory systems and permits incremental memory sizes of 4096 words. The fast access times provided allow the ROM to service high performance microcomputer applications without stalling the processor.

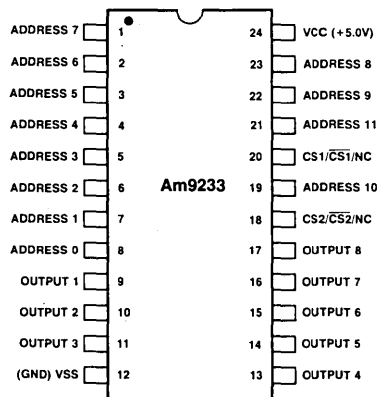

Two programmable Chip Select input signals are provided to control the output buffers. Each Chip Select polarity may be specified by the customer thus allowing the addressing of 4 memory chips without external gating. The outputs of unselected chips are turned off and assume a high impedance state. This permits wire-ORing with additional Am9232/33 devices and other three-state components.

These memories are fully static and require no clock signals of any kind. A selected chip will output data from a location specified by the address present on the address input lines. Input and output voltage levels are compatible with TTL specifications.

Am27S28 • Am27S29

4096-Bit Generic Series Bipolar PROM

DISTINCTIVE CHARACTERISTICS

- High Speed – 55ns max commercial range access time
- Excellent performance over full MIL and commercial ranges
- Highly reliable, ultra-fast programming Platinum-Silicide fuses
- High programming yield
- Low current PNP inputs
- High current open collector and three-state outputs
- Fast chip select
- Access time tested with N^2 patterns
- Pin for pin replacements for industry standard products
- Common Generic PROM series electrical characteristics and simple programming procedures.

GENERIC SERIES CHARACTERISTICS

The Am27S28 and Am27S29 are members of an Advanced PROM series incorporating common electrical characteristics and programming procedures. All parts in this series are produced with a fusible link at each memory location storing a logic LOW and can be selectively programmed to a logic HIGH by applying appropriate voltages to the circuit.

All parts are fabricated with AMD's fast programming highly reliable Platinum-Silicide Fuse technology. Utilizing easily implemented programming (and common programming personality card sets) these products can be rapidly programmed to any customized pattern. Extra test rows are pre-programmed during manufacturing to insure extremely high field programming yields, and produce excellent parametric correlation.

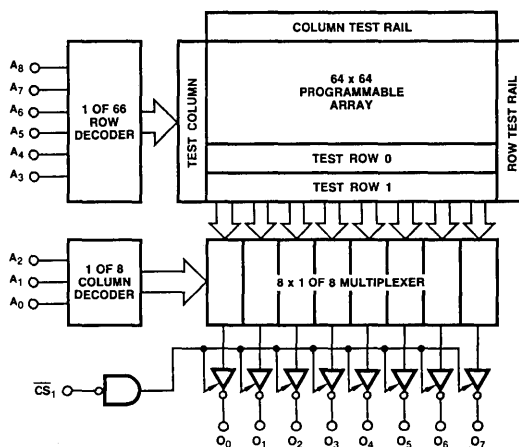

Platinum-Silicide was selected as the fuse link material to achieve a well controlled melt rate resulting in large non-conductive gaps that ensure very stable long term reliability. Extensive operating testing has proven that this low-field, large-gap technology offers the best reliability for fusible link PROMs.

Common design features include active loading of all critical AC paths regulated by a built-in temperature and voltage compensated bias network to provide excellent parametric performance over MIL supply and temperature ranges. Selective feedback techniques have been employed to minimize delays through all critical paths producing the fastest speeds possible from Schottky processed PROMs.

FUNCTIONAL DESCRIPTION

The Am27S28 and Am27S29 are high speed electrically programmable Schottky read only memories. Organized in the industry standard 512 x 8 configuration, they are available in both open collector Am27S28 and three-state Am27S29 output versions. After programming, stored information is read on outputs O_0 - O_7 by applying unique binary addresses to A_0 - A_8 and holding the chip select input, \overline{CS} , at a logic LOW. If the chip select input goes to a logic HIGH, O_0 - O_7 go to the off or high impedance state.

PROGRAMMING

The Am27S28 and Am27S29 are manufactured with a conductive Platinum-Silicide link at each bit location. The output of the memory with the link in place is LOW. The fusible links are opened one at a time by passing current through them from a 20 volt supply which is applied to the memory output after the \overline{CS} input is at a logic HIGH. Current is gated through the addressed fuse by raising the \overline{CS} input from a logic HIGH to 15 volts. After 50 μ sec, the 20 volt supply is removed, the chip is enabled and the output level is sensed to determine if the link has opened. Most links will open within 50 μ sec. Occasionally a link will be stronger and require additional programming cycles. The recommended duration of additional programming periods is 5 msec. If a link has not opened after a total elapsed programming time of 400 msec, further programming of the device should not be attempted. Successive links are programmed in the same manner until all desired bit locations have been programmed to the HIGH level.

Typical current into an output during programming will be approximately 140mA until the fuse link is opened, after which the current drops to approximately 40mA. Current into the \overline{CS} pin when it is raised to 15 volts is typically 1.5mA.

The memories may become hot during programming due to the large currents being passed. Programming cycles should not be continuously applied to one device more than 5 seconds to avoid heat damage. If this programming time is exceeded, all power to the chip including V_{CC} should be removed for a period of 5 seconds after which programming may be resumed.

When all programming has been completed, the data content of the memory should be verified by sequentially reading all words. Occasionally this verification will show that an extra undesired link has been fused. Should this occur, immediately check the programming equipment to make sure that all device pins are firmly contacting the programming socket, that the input signal levels exhibit sufficient noise margins, and that the programming voltages are within the specified limits. All of these conditions must be maintained during programming. AMD PROMs are thoroughly tested to minimize unwanted fusing; fusing extra bits is generally related to programming equipment problems.

PROGRAMMING PARAMETERS

Parameter	Description	Min.	Max.	Units
V_{CCP}	V_{CC} During Programming	5.0	5.5	Volts
V_{IHP}	Input HIGH Level During Programming	2.4	5.5	Volts
V_{ILP}	Input LOW Level During Programming	0.0	0.45	Volts
V_{CSP}	\overline{CS} Voltage During Programming	14.5	15.5	Volts
V_{OP}	Output Voltage During Programming	19.5	20.5	Volts
V_{ONP}	Voltage on Outputs Not to be Programmed	0.0	$V_{CCP}+0.3$	Volts
I_{ONP}	Current into Outputs Not to be Programmed		20	mA
$d(V_{OP})/dt$	Rate of Output Voltage Change	20	250	V/μ sec
$d(V_{EN})/dt$	Rate of \overline{CS} Voltage Change	100	1000	V/μ sec
t_p	Programming Period - First Attempt	50	100	μ sec
	Programming Period - Subsequent Attempts	5.0	15	msec

- Notes:
1. All delays between edges are specified from completion of the first edge to beginning of the second edge; i.e., not to the midpoints.
 2. Delays t_1 through t_4 must be greater than 100ns; maximum delays of 1 μ sec are recommended to minimize heating during programming.
 3. During t_v , a user defined period, the output being programmed is switched to the load R and read to determine if additional pulses are required.
 4. Outputs not being programmed are connected to V_{ONP} through resistor R which provides output current limiting.

SIMPLIFIED PROGRAMMING DIAGRAM

PROGRAMMING EQUIPMENT

Generic programming boards and device adapters are available from the sources listed below. In each case, the programming boards are used in these manufacturer's automatic

programmers to program all AMD generic series bipolar PROMs; individual adapters are required for each basic part type in the series.

SOURCE AND LOCATION	Data I/O Corp. P.O. Box 308 Issaquah, Wash. 98027	Pro-Log Corp. 2411 Garden Road Monterey, Ca. 93940
PROGRAMMER MODEL(S)	Model 5, 7 and 9	M900 and M920
AMD GENERIC BIPOLAR PROM PERSONALITY BOARD	909-1286-1	PM9058
Am27S28 • Am27S29 ADAPTERS AND CONFIGURATOR	715-1413	PA20-4 and 512 x 8 (L)

OBTAINING PROGRAMMED UNITS

Programmed devices may be purchased from your distributor or Advanced Micro Devices. The program data should be submitted in the form of a punched paper tape and must be accompanied by a written truth table. The punched tape can be delivered with your order or may be transmitted over a TWX machine or time-sharing terminal. ASCII BPNF is our preferred paper tape format.

Truth tables are also acceptable, however, much less desirable especially for larger density PROMs. Submission of a truth table requires the generation of a punched paper tape at the distributor or factory resulting in longer lead times, greater possibility of error, and higher cost.

ASCII BPNF

An example of an ASCII tape in the BPNF format is shown below. They can be punched on any Teletype® or on a TWX or Telex machine. The format chosen provides relatively good error detection. Paper tapes must consist of:

1. A leader of at least 25 rubouts.
2. The data patterns for all 512 words, starting with word 0, in the following format:
 - a. Any characters, including carriage return and line feed, except "B".
 - b. The letter "B", indicating the beginning of the data word.
 - c. A sequence of eight Ps or Ns, starting with output O₇.
 - d. The letter "F", indicating the finish of the data word.
 - e. Any text, including carriage return and line feed, except the letter "B".

3. A trailer of at least 25 rubouts.

A P is a HIGH logic level = 2.4 volts.

An N is a LOW logic level = 0.4 volts.

A convenient pattern to use for the data words is to prefix the word (or every few words) with the word number, then type the data word, then a comment, then carriage return and line feed as shown below. There must be no characters between the B and the F except for the eight Ps and Ns. If an error is made in a word, the entire word must be cancelled with rubouts back to the letter B, then the word re-typed beginning with the B.

When TWXing your tape, be sure the tape is in even parity. Parity is not necessary if the tape is mailed.

Am27S30 • Am27S31

4096-Bit Generic Series Bipolar PROM

DISTINCTIVE CHARACTERISTICS

- High Speed – 55 ns max commercial range access time
- Excellent performance over full MIL and commercial ranges
- Highly reliable, ultra-fast programming Platinum-Silicide fuses
- High programming yield
- Low current PNP inputs
- High current open collector and three-state outputs
- Fast chip select
- Access time tested with N^2 patterns
- Pin for pin replacements for industry standard products
- Common Generic PROM series electrical characteristics and simple programming procedures.

GENERIC SERIES CHARACTERISTICS

The Am27S30 and Am27S31 are members of an Advanced PROM series incorporating common electrical characteristics and programming procedures. All parts in this series are produced with a fusible link at each memory location storing a logic LOW and can be selectively programmed to a logic HIGH by applying appropriate voltages to the circuit.

All parts are fabricated with AMD's fast programming highly reliable Platinum-Silicide Fuse technology. Utilizing easily implemented programming (and common programming personal-ity card sets) these products can be rapidly programmed to any customized pattern. Extra test rows are preprogrammed during manufacturing to insure extremely high field programming yields, and produce excellent parametric correlation.

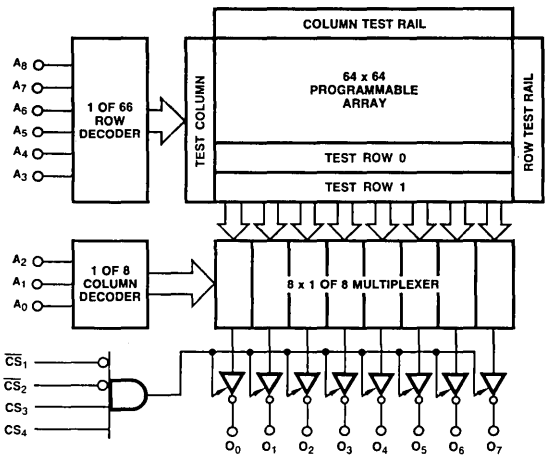

Platinum-Silicide was selected as the fuse link material to achieve a well controlled melt rate resulting in large non-conductive gaps that ensure very stable long term reliability. Extensive operating testing has proven that this low-field, large-gap technology offers the best reliability for fusible link PROMs.

Common design features include active loading of all critical AC paths regulated by a built-in temperature and voltage compensated bias network to provide excellent parametric performance over MIL supply and temperature ranges. Selective feedback techniques have been employed to minimize delays through all critical paths producing the fastest speeds possible from Schottky processed PROMs.

FUNCTIONAL DESCRIPTION

The Am27S30 and Am27S31 are high speed electrically programmable Schottky read only memories. Organized in the industry standard 512 x 8 configuration, they are available in both open collector Am27S30 and three-state Am27S31 output versions. After programming, stored information is read on outputs O_0 - O_7 by applying unique binary addresses to A_0 - A_8 and holding \overline{CS}_1 and \overline{CS}_2 LOW and CS_3 and CS_4 HIGH. All other valid input conditions on \overline{CS}_1 , \overline{CS}_2 , CS_3 and CS_4 place O_0 - O_7 into the OFF or high impedance state.

8192-Bit Generic Series Bipolar PROM

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

- High Speed – 60ns max commercial range access time
- Excellent performance over full MIL and commercial ranges
- Highly reliable, ultra-fast programming Platinum-Silicide fuses
- High programming yield
- Low current PNP inputs
- High current open collector and three-state outputs
- Fast chip select
- Access time tested with N^2 patterns
- Pin for pin replacements for industry standard products
- Common Generic PROM series electrical characteristics and simple programming procedures.

GENERIC SERIES CHARACTERISTICS

The Am27S180 and Am27S181 are members of an Advanced PROM series incorporating common electrical characteristics and programming procedures. All parts in this series are produced with a fusible link at each memory location storing a logic LOW and can be selectively programmed to a logic HIGH by applying appropriate voltages to the circuit.

All parts are fabricated with AMD's fast programming highly reliable Platinum-Silicide Fuse technology. Utilizing easily implemented programming (and common programming personality card sets) these products can be rapidly programmed to any customized pattern. Extra test words are pre-programmed during manufacturing to insure extremely high field programming yields, and produce excellent parametric correlation.

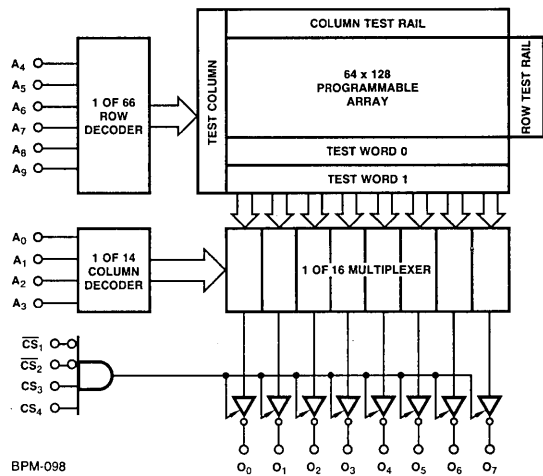

Platinum-Silicide was selected as the fuse link material to achieve a well controlled melt rate resulting in large non-conductive gaps that ensure very stable long term reliability. Extensive operating testing has proven that this low-field, large-gap technology offers the best reliability for fusible link PROMs.

Common design features include active loading of all critical AC paths regulated by a built-in temperature and voltage compensated bias network to provide excellent parametric performance over MIL supply and temperature ranges. Selective feedback techniques have been employed to minimize delays through all critical paths producing the fastest speeds possible from Schottky processed PROMs.

FUNCTIONAL DESCRIPTION

The Am27S180 and Am27S181 are high speed electrically programmable Schottky read only memories. Organized in the industry standard 1024 x 8 configuration, they are available in both open collector Am27S180 and three-state Am27S181 output versions. After programming, stored information is read on outputs O_0-O_7 by applying unique binary addresses to A_0-A_9 and enabling the chip (\overline{CS}_1 , \overline{CS}_2 , low and CS_3 , CS_4 high). Changes of chip select input levels disables the outputs causing them to go to the off or high impedance state.

Notes: 1. Typical limits are at V_{CC} = 5.0V and T_A = 25°C.

2. Not more than one output should be shorted at a time. Duration of the short circuit should not be more than one second.

3. These parameters are not 100% tested, but are periodically sampled.

SWITCHING CHARACTERISTICS OVER OPERATING RANGE
PRELIMINARY DATA

Parameter	Description	Test Conditions	Typ	Max		Units
			5V 25°C	COM'L	MIL	
t_{AA}	Address Access Time	AC Test Load (See Notes 1-3)	40	60	80	ns
t_{EA}	Enable Access Time		20	40	50	ns
t_{ER}	Enable Recovery Time		20	40	50	ns

- Notes: 1. t_{AA} is tested with switch S_1 closed and $C_L = 30\text{pF}$.
 2. For open collector outputs, t_{EA} and t_{ER} are tested with S_1 closed to the 1.5V output level. $C_L = 30\text{pF}$.
 3. For three state outputs, t_{EA} is tested with $C_L = 30\text{pF}$ to the 1.5V level; S_1 is open for high impedance to HIGH tests and closed for high impedance to LOW tests. t_{ER} is tested with $C_L = 5\text{pF}$. HIGH to high impedance tests are made with S_1 open to an output voltage of $V_{OH} - 0.5\text{V}$; LOW to high impedance tests are made with S_1 closed to the $V_{OL} + 0.5\text{V}$ level.

SWITCHING CHARACTERISTICS

Note: Level on output while chip is disabled is determined externally.

PROGRAMMING

The Am27S180 and Am27S181 are manufactured with a conductive Platinum-Silicide link at each bit location. The output of the memory with the link in place is LOW. To program the device, the fusible links are selectively opened.

The fusible links are opened one at a time by passing current through them from a 20 volt supply which is applied to one memory output after the \overline{CS}_1 input is at a logic HIGH. Current is gated through the addressed fuse by raising the \overline{CS}_1 input from a logic HIGH to 15 volts. After 50 μsec , the 20 volt supply is removed, the chip enabled, and the output level sensed to determine if the link has opened. Most links will open within 50 μsec . Occasionally a link will be stronger and require additional programming cycles. The recommended duration of additional programming periods is 5 msec. If a link has not opened after a total elapsed programming time of 400 msec, further programming of the device should not be attempted. Successive links are programmed in the same manner until all desired bit locations have been programmed to the HIGH level.

Typical current into an output during programming will be approximately 140mA until the fuse link is opened, after which

the current drops to approximately 40mA. Current into the \overline{CS}_1 pin when it is raised to 15 volts is typically 1.5mA.

The memories may become hot during programming due to the large currents being passed. Programming cycles should not be applied to one device more than 5 seconds to avoid heat damage. If this programming time is exceeded, all power to the chip including V_{CC} should be removed for a period of 5 seconds after which programming may be resumed.

When all programming has been completed, the data content of the memory should be verified by sequentially reading all words. Occasionally this verification will show that an extra undesired link has been fused. Should this occur, immediately check the programming equipment to make sure that all device pins are firmly contacting the programming socket, that the input signal levels exhibit sufficient noise margins, and that the programming voltages are within the specified limits. All of these conditions must be maintained during programming. AMD PROMs are thoroughly tested to minimize unwanted fusing; fusing extra bits is generally related to programming equipment problems.

PROGRAMMING PARAMETERS

Parameter	Description	Min.	Max.	Units
V_{CCP}	V_{CC} During Programming	5.0	5.5	Volts
V_{IHP}	Input HIGH Level During Programming	2.4	5.5	Volts
V_{ILP}	Input LOW Level During Programming	0.0	0.45	Volts
V_{CSP}	\overline{CS}_1 Voltage During Programming	14.5	15.5	Volts
V_{OP}	Output Voltage During Programming	19.5	20.5	Volts
V_{ONP}	Voltage on Outputs Not to be Programmed	0	$V_{CCP} + 0.3$	Volts
I_{ONP}	Current into Outputs Not to be Programmed		20	mA
$d(V_{OP})/dt$	Rate of Output Voltage Change	20	250	$V/\mu\text{sec}$
$d(V_{CS})/dt$	Rate of \overline{CS}_1 , Voltage Change	100	1000	$V/\mu\text{sec}$
t_p	Programming Period – First Attempt	50	100	μsec
	Programming Period – Subsequent Attempts	5.0	15	msec

- Notes: 1. All delays between edges are specified from completion of the first edge to beginning of the second edge; i.e., not to the midpoints.
 2. Delays t_1 , t_2 , t_3 and t_4 must be greater than 100 ns; maximum delays of 1 μsec are recommended to minimize heating during programming.
 3. During t_v , a user defined period, the output being programmed is switched to the load R and read to determine if additional pulses are required.
 4. Outputs not being programmed are connected to V_{ONP} through resistor R which provides output current limiting.

PROGRAMMING EQUIPMENT

Generic programming boards and device adapters are available from the sources listed below. In each case, the programming boards are used in these manufacturer's automatic

programmers to program all AMD generic series bipolar PROMs; individual adapters are required for each basic part type in the series.

SOURCE AND LOCATION	Data I/O Corp. P.O. Box 308 Issaquah, Wash. 98027	Pro-Log Corp. 2411 Garden Road Monterey, Ca. 93940
PROGRAMMER MODEL(S)	Model 5, 7 and 9	M900 and M920
AMD GENERIC BIPOLAR PROM PERSONALITY BOARD	909-1286-1	PM9058
Am27S180 • Am27S181 ADAPTERS AND CONFIGURATOR	715-1545-2	PA24-13 and 1024 x 8 (L)

OBTAINING PROGRAMMED UNITS

Programmed devices may be purchased from your distributor or Advanced Micro Devices. The program data should be submitted in the form of a punched paper tape and must be accompanied by a written truth table. The punched tape can be delivered with your order or may be transmitted over a TWX machine or time-sharing terminal. ASCII BPNF is our preferred paper tape format.

Truth tables are also acceptable, however, much less desirable especially for larger density PROMs. Submission of a truth table requires the generation of a punched paper tape at the distributor or factory resulting in longer lead times, greater possibility of error, and higher cost.

ASCII BPNF

An example of an ASCII tape in the BPNF format is shown below. They can be punched on any Teletype® or on a TWX or Telex machine. The format chosen provides relatively good error detection. Paper tapes must consist of:

1. A leader of at least 25 rubouts.
2. The data patterns for all 1024 words, starting with word 0, in the following format:
 - a. Any characters, including carriage return and line feed, except "B".
 - b. The letter "B", indicating the beginning of the data word.
 - c. A sequence of eight Ps or Ns, starting with output O₇.
 - d. The letter "F", indicating the finish of the data word.
 - e. Any text, including carriage return and line feed, except the letter "B".
3. A trailer of at least 25 rubouts.

A P is a HIGH logic level = 2.4 volts.
An N is a LOW logic level = 0.4 volts.

A convenient pattern to use for the data words is to prefix the word (or every few words) with the word number, then type the data word, then a comment, then carriage return and line feed as shown below. There must be no characters between the B and the F except for the eight Ps and Ns. If an error is made in a word, the entire word must be cancelled with rubouts back to the letter B, then the word re-typed beginning with the B.

When TWXing your tape, be sure the tape is in even parity. Parity is not necessary if the tape is mailed.

Am27S184 • Am27S185

8192-Bit Generic Series Bipolar PROM

PRELIMINARY DATA

DISTINCTIVE CHARACTERISTICS

- Excellent performance over full MIL and commercial ranges
- Highly reliable, ultra-fast programming Platinum-Silicide fuses
- High programming yield
- Low current PNP inputs
- High current open collector and three-state outputs
- Fast chip select
- Access time tested with N^2 patterns
- Pin for pin replacements for industry standard products
- Common Generic PROM series electrical characteristics and simple programming procedures.

GENERIC SERIES CHARACTERISTICS

The Am27S184 and Am27S185 are members of an Advanced PROM series incorporating common electrical characteristics and programming procedures. All parts in this series are produced with a fusible link at each memory location storing a logic LOW and can be selectively programmed to a logic HIGH by applying appropriate voltages to the circuit.

All parts are fabricated with AMD's fast programming highly reliable Platinum-Silicide Fuse technology. Utilizing easily implemented programming (and common programming personality card sets) these products can be rapidly programmed to any customized pattern. Extra test words are pre-programmed during manufacturing to insure extremely high field programming yields, and produce excellent parametric correlation.

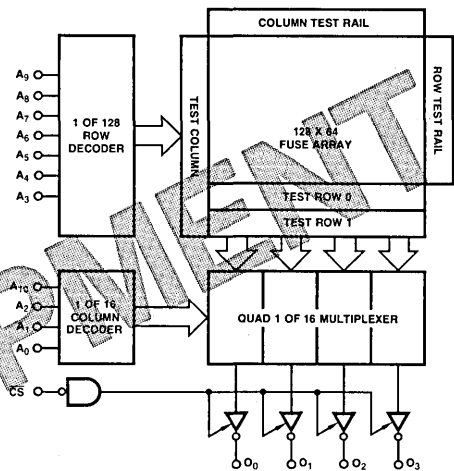

Platinum-Silicide was selected as the fuse link material to achieve a well controlled melt rate resulting in large non-conductive gaps that ensure very stable long term reliability. Extensive operating testing has proven that this low-field, large-gap technology offers the best reliability for fusible link PROMs.

Common design features include active loading of all critical AC paths regulated by a built-in temperature and voltage compensated bias network to provide excellent parametric performance over MIL supply and temperature ranges. Selective feedback techniques have been employed to minimize delays through all critical paths producing the fastest speeds possible from Schottky processed PROMs.

FUNCTIONAL DESCRIPTION

The Am27S184 and Am27S185 are high speed electrically programmable Schottky read only memories. Organized in the industry standard 2048 x 4 configuration, they are available in both open collector Am27S184 and three-state Am27S185 output versions. After programming, stored information is read on outputs O_0 - O_3 by applying unique binary addresses to A_0 - A_{10} and holding the chip select input \overline{CS} LOW. If the chip select input goes to a logic HIGH, O_0 - O_3 go to the off or high-impedance state.

PROGRAMMING

The Am27S184 and Am27S185 are manufactured with conductive Platinum-Silicide link at each bit location. The output of the memory with the link in place is LOW. To program the device, the fusible links are selectively opened.

The fusible links are opened one at a time by passing current through them from a 20 volt supply which is applied to one memory output after the \overline{CS} input is a logic HIGH. Current is gated through the addressed fuse by raising the \overline{CS} input from a logic HIGH to 15 volts. After 50 μ sec, the 20 volt supply is removed, the chip enabled, and the output level sensed to determine if the link has opened. Most links will open within 50 μ sec. Occasionally a link will be stronger and require additional programming cycles. The recommended duration of additional programming periods is 5 msec. If a link has not opened after a total elapsed programming time of 400 msec, further programming of the device should not be attempted. Successive links are programmed in the same manner until all desired bit locations have been programmed to the HIGH level.

Typical current into an output during programming will be approximately 140mA until the fuse link is opened, after which

the current drops to approximately 40mA. Current into the \overline{CS} pin when it is raised to 15 volts is typically 1.5mA.

The memories may become hot during programming due to the large currents being passed. Programming cycles should not be applied to one device more than 5 seconds to avoid heat damage. If this programming time is exceeded, all power to the chip including V_{CC} should be removed for a period of 5 seconds after which programming may be resumed.

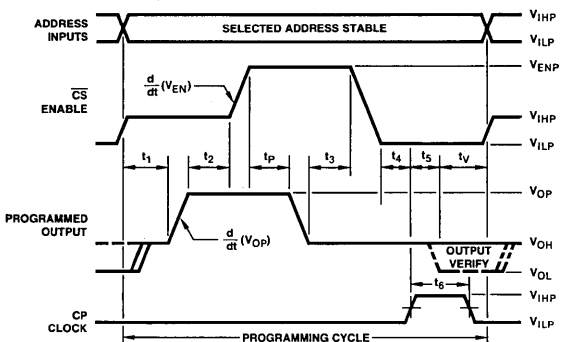

When all programming has been completed, the data content of the memory should be verified by sequentially reading all words. Occasionally this verification will show that an extra undesired link has been fused. Should this occur, immediately check the programming equipment to make sure that all device pins are firmly contacting the programming socket, that the input signal levels exhibit sufficient noise margins, and that the programming voltages are within the specified limits. All of these conditions must be maintained during programming. AMD PROMs are thoroughly tested to minimize unwanted fusing; fusing extra bits is generally related to programming equipment problems.

the AmZ8000 Microprocessor
and the 8080A, 8085A, Z80 & 8048

For Total Capability, AMC gives you the AmSYS 8/8 Microcomputer Development System

SYSTEM DESCRIPTION

The AmSYS 8/8 is designed to support a variety of microprocessors that include the AmZ8000, Z80, Am9080, Am8085, and Am8048.

This system is especially designed to support the AmZ8000 CPU in both hardware and software development. An AmZ8000 Macro Assembler, linker and line oriented editor give the system powerful software development tools. The use of the RTE 8/8050 In-Circuit Emulator for AmZ8000 hardware/software debug and availability of high level languages allow the user great flexibility in development of AmZ8000 products.

The basic system is contained in a single enclosure that fits on a desk top. It has the option of being rack mountable in a 19" relay rack by the addition of slide mounts. It has 64K bytes of main memory, two single density floppy disk drives, providing 512K bytes of storage, an RS232 serial port and two parallel I/O channels as standard features in the system. This system contains extra card slots for use for prototyping hardware.

The AmSYS 8/8 has a multi-master bus structure that allows multiple 8 and 16 bit CPUs to be used at the same time. This bus structure allows the system to be easily upgraded to a full 16 bits by replacing the CPU board on the bus and adding the appropriate software.

The AmSYS 8/8 has very powerful software included as part of the standard system to be delivered. This software includes a Disk Operating system, an excellent text editor, debugger, library manager and linking loader. The powerful macroassemblers included support the AmZ8000 and the 8080, 8085, & Z80. Optionally, an 8048 macroassembler can be added.

The AmSYS 8/8 features the use of Pascal along with extended Basic, Fortran IV and Cobol for high level language support. A Pascal program can be compiled to generate either Am9080 or AmZ8000 code.

In-Circuit Emulation capability is available for both 8 & 16 bit processors. This emulation support is optional for the AmZ8000, Z80, 8080, 8085, & 8048 microprocessors.

The AmSYS 8/8 also has a number of peripherals that are optional to the system. These include double density Floppy Disk Drives, 60, 120 CPS and 300 LPM Line Printers, CRT's, and soon a cartridge disk drive.

SYSTEM FEATURES

Complete Turnkey Development System with Powerful Hardware including:

- Microprocessor CPU
- 64 kilobytes of read/write main memory
- Serial interface RS232 compatible
- Two parallel Channels
- Power up Monitor
- Dual Floppy Disk Drives with 512K bytes of storage capacity
- Extra card slots for prototyping
- Multi-master bus

Powerful Software Including:

- AMDOS Disk Operating System
- Sophisticated Editor
- Debugger
- Macroassemblers for AmZ8000, Z80, 8080, 8085
- Translator to Z8000
- Linkers

Powerful Options Including:

- High level languages
 - Pascal
 - Extended Basic
 - Fortran
 - Cobol
- Line Printers 60 & 120 CPS & 300 LPM
- CRT w/extra keypad
- PROM Programmer
- Double Density Floppy Disk Drives
- Expansion Chassis containing two additional Disk Drives
- Additional Serial I/O lines
- In-Circuit Emulation for
 - AmZ8000
 - 8080, 8085
 - 8048, 8021, 8049, & 8035

Additional Features that will be available in the near future include:

- Expansion to 1 megabyte of main memory
- Upgrade to AmZ8000 CPU
- Cartridge Disk
- Additional High level languages
- Expansion chassis for more Main Memory

System Hardware Features

The AmSYS 8/8 features the use of a multiple master bus structure. This allows the system to use both 8 and 16 bit microprocessors. The SYS 8/8 can be upgraded to include a 16 bit CPU board and appropriate software so that both microprocessors may operate simultaneously using the multi-master bus structure. This allows the system user maximum flexibility in the development of hardware & software.

MAIN CPU MODULE

The Central Processor (CPU) module uses an 8-bit Am9080 microprocessor. This module includes a ROM based auto bootstrap that first performs a diagnostic confidence check of the system and next loads the operating system from the system disk drives. The CPU module has multi-master capability allowing operation in a master/slave environment with other 8-bit CPU modules or the 16-bit CPU module. The CPU module also includes 4 high speed DMA channels and 8 vectored interrupt channels. An optional Am9511A/Am9512 Arithmetic Processing Unit can be added to provide high speed fixed and floating point computations and floating point transcendental functions to the system. A 1.2KHz crystal controlled Real Time Clock is also part of this module.

MEMORY MODULE

This memory module is organized as a 64 Kilobyte storage unit. This module is organized to provide either 8 or 16-bit compatibility. It also contains internal memory refresh capability and is multimaster bus compatible.

FLOPPY DISK MODULE

This module features a controller with its own internal microprocessor and controls up to 4 single or double sided floppy disks. This controller has a 20-bit address and DMA capability allowing it to address up to 1 megabyte of main memory.

This module is IBM 3740 soft sector compatible. AmSYS 8/8 provides a capacity of 512K bytes of disk storage in the basic system. This storage capacity is contained on two floppy disk drives each with 256K bytes of storage.

On board buffer memory allows high speed data transfer to the CPU module.

Additional storage is available by the use of the optional double density disk controller or by the addition of a double disk drive expansion chassis.

CHASSIS

The AmSYS 8/8 is normally supplied as a desk top chassis. As an option, this chassis can be rack mounted with the addition of a slide mount kit. It contains seven card slots with three available for use with prototyping or additional I/O P.C. cards. This chassis is totally self contained with cooling and internal power supplies.

The front of the chassis contains an illuminated off/on switch and also a system reset button. The rear of this unit contains all I/O and power connections including fuses.

The system includes as standard, one serial port and two parallel channels. The serial port is RS232 compatible and allows the user to connect a variety of terminals to the system. The parallel channels can be used to connect high and low speed printers or other peripheral devices. Additional I/O ports can be added to the System by the use of plug in cards.

The parallel channels each consist of 24 parallel I/O lines. These lines can be configured under software control as sets of input, output, or bidirectional I/O lines. Sockets are provided within the system to add drivers or terminators to each line.

The Am96/4016 Evaluation Board can be plugged into one of the empty card cage slots to provide a 16 bit execution module within AmSYS 8/8. The board is powered by the system power supplies and uses the system floppy disks via the parallel up-load/down-load link to the CPU module. A second card cage slot can be used to upgrade the Evaluation Board RAM to 64k.

7

Development Software

The AmSYS 8/8 combines a sophisticated set of hardware along with an even more powerful set of software to make the complex process of product development easier to handle for the user. This software includes an Editor, File Manager, Macroassemblers, disk operating system, and a number of high level languages.

The software that comes standard with the AmSYS 8/8 is the AMDOS® Operating System, AmZ8000, 8080, 8085, and Z80 Macro Assemblers, a linking loader, a powerful Editor, debugger and Translator. Optional software includes an 8048 Macroassembler, Pascal, Fortran, Basic, Cobol, and upload/download packages for execution of AmZ8000 code. The following describes the major software modules provided with or as options to the system.

OPERATING SYSTEM

AMDOS 8 is the disk operating system for the AmSYS 8/8 and provides rapid access to programs through a comprehensive file management structure. A file subsystem supports a named file structure allowing the dynamic allocation of file space as well as sequential and random file access. System calls are provided permitting files to be opened, closed, renamed, read, written onto disk, or searched for by name. The AMDOS 8 file system allows a large number of distinct programs to be stored in both source and machine executable forms. AMDOS 8 also provides the ability to access disk storage, Terminal, Printer, and support for PROM programming.

LIBR is an object file library manager that permits the creation and listing of user libraries for the Am8080, Am8085, and Z80 microcomputers. Individual object-module files may be selectively processed to extract modules from existing libraries or relocatable object files to build libraries for later selective searching by the LINK linkage editor.

EDIT is a line-oriented context editor providing the user the ability to create and modify ASCII source text for the AmSYS 8/8 compilers and assemblers. A powerful set of user commands is available to simplify the task of generating line oriented or character oriented files.

In the line oriented mode, numbers will automatically be added to new lines as they are appended to the file. Also, as lines are inserted or deleted within the text, these numbers are updated. The users position within the file can then be controlled by referring to the desired line number. The ALTER mode allows the user to insert, delete, and replace individual characters, strings in a line, or a range of lines in the source file. Searching for occurrences of characters or strings is also included along with substitution of characters or strings into the source text.

DEBUG is designed to provide dynamic interactive testing and debugging of 8-bit programs generated in the AmSYS 8/8 system. This program consists of two parts: The debug nucleus and the assembler/disassembler module. These along with powerful user commands make debug a very valuable tool for debugging software programs.

MACRO ASSEMBLERS

Two macroassemblers come as part of the standard AmSYS 8/8. These are MACRO 8 supporting the 8080, 8085, and Z80 microprocessors and MACRO 8000 for support of the AmZ8000 microprocessor. An optional macroassembler supports the 8048 family.

MACRO 8 is a comprehensive macroassembler providing the ability to assemble relocatable 8080/ 8085/ Z80 programs. These can be combined with object files produced by high-level language compilers (using LINK) to form composite executable programs. In addition to comprehensive conditional assembly directives, hierarchical expression evaluation, definition of alternate entry-points and external symbols, MACRO 8 provides a companion cross-reference facility (CREF8) which lists the assembler output with line numbers. An alphabetic variable-name directory is also provided and includes line number references for each occurrence of the variable name.

MACRO 8000 is a powerful macroassembler providing the ability to assemble relocatable AmZ8000 programs. This assembler includes sophisticated features like segmentation, block-structured program organization, algorithmic assignment statements, IF-THEN-ELSE conditional assembly, and execution provisions as well as recursive macro calls.

LINK 8 & LINK 8000 are linkage editors used to combine the relocatable module ready for loading as a program. Link 8 supports the editing of 8 bit segments. The linkers process a series of interactive subcommands that specify files to be linked, files to be searched for satisfaction of unresolved external references, and specific directives which allow a memory map to be printed or direct execution to be initiated.

TRANZ 8000 is an AmZ8000 translator program accepting standard 8080, 8085, and Z80 source code as input and provides standard AmZ8000 source code as output, aiding the user in conversion of existing 8-bit programs to the AmZ8000 environment.

HIGH LEVEL LANGUAGES

PASCAL is a new, up-to-date, language developed for users who are seeking new features to solve today's problems. PASCAL incorporates new features like the concept of variable data types: bits, bytes, words, records, sets, scalars . . . and others that are appropriate to the solution of complex problems. The block structured nature of the language permits the user to create software in a structured environment resulting in a lower development costs, more concise documentation and lower maintenance costs.

The AMC PASCAL is upwards compatible with Jensen and Wirth PASCAL. Extensions provided include:

Interactive files	Comparison of arrays
Untyped files	Comparison of records
Random access of files	Text intrinsics
Strings intrinsics	

The Pascal user can compile a Pascal program and then execute the program on AmSYS 8/8 with the Pascal interpreter and run-time library. The output of this compiler is a special code called P-code and is compatible with the well-known UCSD P-code. The Pascal interpreter executes the P-code instructions when running the Pascal program. The run-time library routines are used as needed in Pascal program execution.

The Pascal user can compile a Pascal program and then generate either 8080, or AmZ8000 code. For 8080 code generation, an 8080 macro library, the MACRO 8 8-bit assembler, and the linker LINK 8 are automatically used. For AmZ8000 code generation, the AmZ8000 macro library, MACRO8000 16-bit assembler, and the linker LINK 8000 are used automatically.

FORTRAN has long been accepted as the standard for scientific programming and is the "native" language of many professional programmers. AMC supports FORTRAN with a compiler conforming to the ANSI 1966 specification for the 8080 microprocessor in the AmSYS 8/8 system.

Full conformance to the ANSI standard insures that accumulated libraries of FORTRAN programs will be immediately usable in the AmSYS 8/8 environment. AMC FORTRAN opens the door to the richest traditions of scientific programming in a small, inexpensive environment.

BASIC is one of the most comprehensive 8-bit BASIC language software programs available today. It contains many unique features not found in other implementations, like:

- a. Direct access to the CPU I/O Ports
- b. Full Print Using Capability
- c. Trace facilities
- d. Four variable types — Integer, String, Single (7 digits) and Double (16 digits) precision floating point.

These are only a few of the features available in AMC's BASIC. It also has one of the largest sets of statements making it a very powerful language available to the AmSYS 8/8 user.

COBOL has been developed in strict accordance to ANSI '74 standards for support of the 8080 within the AmSYS System. At the root of the language is a full ANSI '74 Level 1 COBOL. Beyond that, many Level 2 features have been incorporated to make AMC's COBOL more powerful in every instance where the fundamental speed and size of the package is extremely important. In addition to this, special display-oriented features (ACCEPT, DISPLAY, etc.) have been added to the language in anticipation of a strong emphasis on interactive data entry applications in the microcomputer environment. A powerful interactive debug structure has also been added to greatly decrease program development time.

7

In-Circuit Emulation

The AmSYS 8/8 Development System provides optional In-Circuit Emulation capability to support a wide range of microprocessors including the AmZ8000, 8080, 8085, Z80, and 8048. The AmSYS series of emulators contain many unique features to assist the designer in the debugging of hardware and software. There are two types of emulators in the AmSYS 8/8 Development System Series. These are:

- (1) AmSYS 8/8800 In-Circuit Emulator series for 8-bit microprocessors including individual emulators for the 8080, 8085, Z80, and 8048.
- (2) AmSYS 8/8050 In-Circuit Emulator for the AmZ8001 and 8002 microprocessors.

These in-circuit emulators come as complete subsystems and are connected to the AmSYS 8/8 by a high speed serial I/O interface. Each emulator provides its own internal memory storage to give the user real time emulation.

AmSYS 8/8050 16 BIT IN-CIRCUIT EMULATION SUBSYSTEM

The AmSYS RTE 8/8050 Emulator has been designed especially to support the AmZ8000 microprocessor. This subsystem provides real time emulation for both the AmZ8001 segmented and AmZ8002 non-segmented versions.

The AmSYS RTE 8/8050 Emulator has a number of key features including TRACE, 8 trigger points, memory mapping of internal high speed static RAM, and medium speed dynamic RAM providing real time emulation in the user's target system. The AmSYS RTE 8/8050 Emulator has two modes of operation:

- 1) Interrogation — this mode allows the user to access AmZ8000 resources, registers, I/O ports, and target RAM.
- 2) Emulation — this mode allows the designer the choice of an internal or user designated clock for software execution or emulation in his target system

RTE 8/8050 provides two types of memory for the user. One type is high speed static memory providing the user with real time emulation at up to 4 MHz for the AmZ8000 with no wait states. It is available in 4K or 8K bytes. The second type is medium speed dynamic RAM available in 64K or 128K byte increments with one wait state at 4 MHz and is expandable up to 192K bytes.

RTE 8/8050 allows for memory mapping on 1K byte boundaries within the AmZ8000 8M byte address space .

There are up to 8 trigger points available to the user that can be used as breakpoints, enabling patching trace qualifiers or allowing selective trace after the breakpoint is encountered. Two compound breakpoints are also permitted. These allow breakpoints on a value within or outside a specified range, i.e., address, data, address and data, I/O address, I/O data, I/O, address and data.

Trace is an integral part of the system. This feature provides for two basic modes of operation. These are:

- Micro Trace — this saves Address/Data bus and status together with 8 or 16 user designated probes every machine cycle.
- Macro Trace — this saves Address bus and status during T1 displaying address bus in HEX format and status in binary and symbolically decoded form. Also saved is Data Bus during T3 in disassembled form with operand values in HEX format.

The Micro or Macro trace can be enabled only for selected cycles by use of a trigger point match. A user option is available to tag each traced event with a 16 bit number for counting the number of machine states since the counter was enabled. A unique feature of the RTE 8/8050 is the PATCH allowing patching of ROM/RAM code while running in user memory. Up to 4 patches are allowed with up to 16 locations each providing a substantial improvement over conventional patching techniques that require subroutines.

The trace RAM buffer is 256 words deep and 48 bits wide and is expandable to 1024 words. This unit has the ability to time stamp each entry in the trace buffer.

The RTE 8/8050 Emulation Subsystem is provided as a stand-alone unit with integral power supplies, emulator module, trace module and serial I/O port. Programs prepared on the AmSYS 8/8 development system are down-line loaded to the emulator subsystem under the control of the emulator control processor, which services and issues all emulator commands. RTE 8/8050 Emulator commands and results can be displayed via the AmSYS 8/8 Development System CRT or via a separate CRT console plugged into the RTE 8/8050 Subsystem. (This configuration leaves the AmSYS 8/8 Development System free to perform software development, i.e., assembly, editing, etc.) The RTE 8/8050 Emulator has been designed to give the designer maximum support in system debugging.

AmSYS 8/8800 8-BIT IN-CIRCUIT EMULATION SUBSYSTEM

The RTE 8/8800 in-circuit emulator is designed to allow replacement of the target microprocessor during the debugging and prototyping phase. It provides the user with real time emulation of each designated microprocessor together with sophisticated debug tools for hardware/software integration resulting in a reduction of overall development time.

AmSYS RTE 8/8800 provides versatile emulation capabilities for the 8080, 8085, Z80A, or 8048 depending upon the personality module being used. It also has the capability to examine and alter registers, memory, and I/O ports. The emulator utilizes the users system clock, thus eliminating potential timing problems caused by separate clocks.

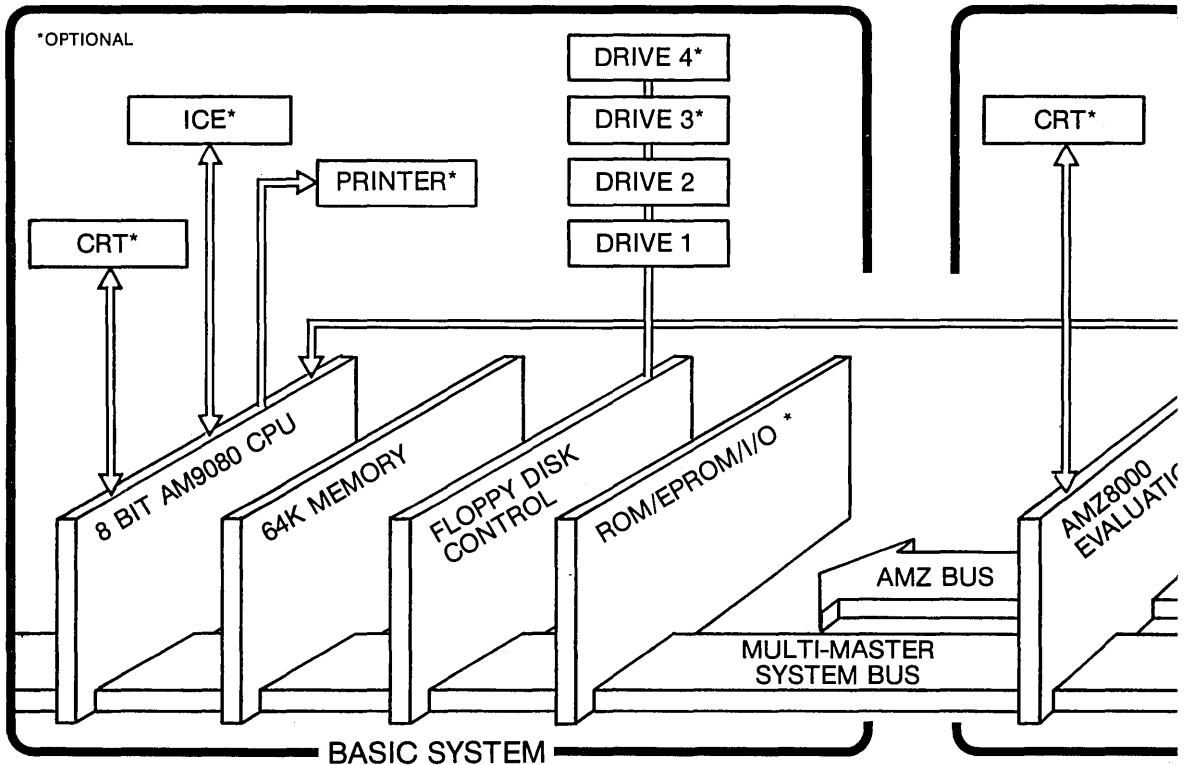

There are up to 8K bytes of high speed Static RAM Emulator memory for mapping on 1K byte boundaries in the target system, thereby utilizing known memory into the target system. This unit has a real time trace for storing the last 128 bus operations as well as the 8 external probes. During selected emulator operations, 16 address lines, 8 data lines, and the clock signal are stored during emulator operation. Disassemblers for each supported microprocessor are provided together with host software for the AmSYS 8/8 Development System.

The AmSYS RTE 8/8800 in-circuit emulator consists of a basic sub-system containing a trace module, emulator module, serial communications module and 8K bytes of high speed static RAM. The connection to the AmSYS 8/8 Development System is via a serial I/O port. Each microprocessor personality module is supplied with its own emulator pod attached to a cable terminating in a 40-pin connector to provide the interface to the target system. Host software operating on AmSYS 8/8 provides interrogation mapping and a command structure for the RTE 8/8800 in-circuit emulators.

The AmSYS 8/8 is Easy to Adapt

The AmSYS 8/8 is designed to allow easy addition or reconfiguration into a more powerful system. These optional additions and configurations allow execution and debug of AmZ8000 programs, the addition of Double Density Floppy Disks, Hard memory expansion, and reconfiguration as an AmZ8000 based development system.

AmZ8000 EXECUTION AND DEBUG (8/8610 and 8620)

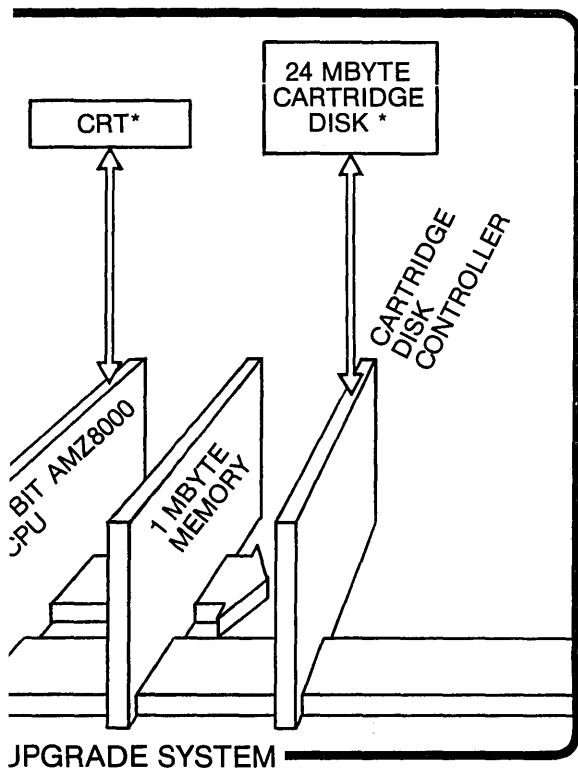

The 8/8610 up-load/down-load package provides an ideal breadboarding, software execution, and debug tool when used with the AmSYS 8/8 development system. It features the AMC 96/4016 AmZ8000 Evaluation Board. AmZ8000 programs generated on AmSYS 8/8 can be down-loaded into or up-loaded from RAM on the Evaluation board where the resident monitor allows execution and debugging to take place under the control of the AmSYS 8/8 console. This Evaluation board provides the user with 8K byte RAM. The 8/8610 can be upgraded to the 8/8620 package with the addition of the 64k RAM board and the AmZ bus motherboard. This expands the RAM storage of the Evaluation Board to 64k. The connection between the RAM board and the Evaluation Board is via the AmZ address and data bus. These options are conveniently packaged as options to AmSYS 8/8.

ADDITIONAL FLOPPY DISK DRIVES

The Floppy Disk controller contained within the AmSYS S 8/8 has the capability of addressing up to four (4) Floppy Disk drives. The addition of the optional 8/8510 Floppy Disk chassis gives the user two (2) additional Floppy Disk drives.

DUAL DENSITY FLOPPY DISK EXPANSION

AmSYS 8/8 can be configured to accept Dual Density Floppy Disk capability. This will give the user Floppy Disk storage capacity of up to 1024K bytes within the AmSYS 8/8. This expansion can be accomplished as a field upgrade.

HARD DISK

AmSYS 8/8 is designed for the addition of a Hard Disk with bulk storage of up to 24 megabytes. This Hard Disk option will be available in the near future to be added to the present 8 bit operating system and also as part of an upgrade to the AmZ8000 based development system.

This Hard Disk option will give the user access to larger amounts of bulk storage and also increases his system throughput.

AmZ8000 EVALUATION BOARD

For evaluation of the AmZ8000, the 96/4016 provides a standalone monoboard computer. The 4016 has 8k bytes of dynamic RAM, 2 serial RS-232 ports, 24 parallel I/O lines, and 3-16 bit counters. A 4k byte monitor program provides debug capability and an interface to the optional 8k line by-line assembler. The monitor also provides the drivers necessary to up-load or down-load files through the parallel or serial interface. The 96/4016 is SBC form factor compatible and can plug into AmSYS 8/8 to get its power from the P1 connector. The memory and I/O on the board can be expanded through the AmZ bus on the P2 connector.

AmZ8000 UPGRADE

The AmSYS 8/8 multimaster bus provides an 8/16 bit data bus with 20 address lines. The peripheral controllers and memory boards all have 8/16 bit compatibility and allow the reconfiguration of the AmSYS 8/8 into a powerful AmZ8000 based development system. The Am9080 board is replaced by the AmZ8000 CPU board, allowing up to 1M byte addressing capability. The addition of AMC's multitasking foreground background system, together with additional 64K or 128K byte RAM memory modules and AmZ8000 software development programs provide the user with a powerful 16-bit system with greatly increased utility and performance.

SPECIFICATIONS

CPU

Am9080 Upgradable to AmZ8000 (see sections entitled "Options")

Memory

64K bytes standard

Disk Storage

512K bytes (2 Single Density Floppy disks, 256K bytes each) (Dual Density is optional) (see section entitled "Optional Upgrades")

I/O Channels

1 serial port RS232 compatible
2 parallel I/O channels consisting of three 8-bit ports each

Interrupt

8 fully programmable vectored channels

AC Power Requirement

60 Hz, 115 VAC std.
100, 120, 220, 240 VAC optional
50/60 Hz Optional

Environmental Requirements

Operating Temperature: 10°C to +40°C
Humidity: 10% - 90% relative (non-condensing)

Physical Characteristics

Dimensions: 24" deep, 17" wide, 11" high
Weight: 60 lbs.
User Panel: Contains: a) on/off switch, power indicator
b) system reset
Chassis: Desk top stds., rack mountable (optional)

Baud Rates

Selectable 50-9600 Baud

Cooling

Internal fans

Standard System Includes the Following:

Am9080 CPU
64K Bytes RAM
512K Bytes Disk storage (2 single sided floppy disks)
1 RS232 serial port
6 8-bit parallel ports
1 Chassis consisting of 7 Card slots
AmZ8000 Macroassembler
AmZ8000 Translator
8080, 8085, and Z80 Macroassemblers
Linker
Editor
Debugger
AMDOS 8 Disk Operating System
1 set System Documentation
2 Diskettes
Multi-master Bus

Optional Items

Universal Prototyping Board
High-Speed Extender Board
Additional Serial and Parallel I/O Ports
Expansion Chassis with 2 floppy disk drives
CRT Terminal
Line Printers 60 CPS, 120 CPS, and 300 LPM
FORTRAN (8 bit)
Extended BASIC (8 bit)
PASCAL (8 bit and 16 bit)
COBOL (8 bit)
9511/9512 Arithmetic Processing Unit
8048, 8049, 8021 Macroassembler
8048, 8049, 8021 In-Circuit Emulation/TRACE
8080 In-Circuit Emulation/TRACE
8085 In-Circuit Emulation/TRACE
Z80 In-Circuit Emulation/TRACE

Options and Upgrades

(not available with initial shipments—contact your AMD salesman for delivery information)
Z8000 In-Circuit Emulation/TRACE
Double Density Floppy Disk Drives
Expansion to 1 megabyte of Main Memory
AmZ8000 Microcomputer Board Upgrades
Cartridge Disk with Capabilities of 12 or 24 Megabytes
High Level 16-bit languages
Additional Expansion chassis

AmSYS 8/8 Ordering Information

PART NO.	DESCRIPTION
8/8010	Standard AmSYS 8/8 Development System 117V, 60 Hz
8/8012	Standard AmSYS 8/8 Development System 117V, 60 Hz Double Density Floppy Disks
8/8020	Standard AmSYS 8/8 Development System 220V, 50 Hz
8/8022	Standard AmSYS 8/8 Development System 220V, 50 Hz Double Density Floppy Disks
8/8030	Standard AmSYS 8/8 Development System 100V, 50 Hz
8/8032	Standard AmSYS 8/8 Development System 100V, 50 Hz Double Density Disks
8/3310	Serial I/O Board (4 Ports)
8/5032	ROM/EPROM Board I/O Board
8/6410	Univ. Prototyping Board
8/6420	High Speed Extender Board
8/8210	CRT with extra key pad
8/8310	Line Printer 120 CPS
8/8340	Line Printer 300 LPM
8/8410	Fortran 8
8/8420	Basic 8
8/8430	Cobol 8
8/8440	Pascal compiler (with code generators)
8/8610	Up/Down Load Execution Package w/8K bytes
8/8620	Up/Down Load Execution Package w/64K bytes
8/8800	In-Circuit Emulator Subsystem
8/8880	8080 In-Circuit Emulator POD
8/8885	8085 In-Circuit Emulator POD
8/8888	Z80 In-Circuit Emulator POD
8/8848	8048 In-Circuit Emulator POD
8/8050	Z8000 In-Circuit Emulator Subsystem
8/8250	Diskette Package of 10
8/8510	Optional Floppy Disk Chassis (adds add'l two Floppy Disk drives to system)

NOW! Evaluate the features of the AmZ8000 . . . develop software . . . execute programs with **THE AMC 96/4016 EVALUATION BOARD.**

The new generation of microprocessors is here. Now you can evaluate the AmZ8000 with the system-oriented **AMC 96/4016 Evaluation Board** that makes it easy to utilize the latest microcomputer technology. The **AMC 96/4016 Evaluation Board** puts a versatile and intelligent tool in the hands of engineers, designers and programmers allowing them to explore the exceptional capabilities of the AmZ8000. The **AMC 96/4016** integrates powerful hardware and extensive software resources on an assembled and tested printed-circuit board that allows the evaluation of the AmZ8000 by the addition of a power supply and I/O device. Power can be provided by plugging the board into an SBC 80 type card cage, AMC's development system, or with a lab supply. Two ports are provided to interface to a CRT terminal or to the 96/4016-KBD keyboard/display board.

Some of the features of the **AMC 96/4016 Evaluation Board** are:

- Fully assembled and tested computer board
- AmZ8002 Microprocessor – 4MHz operation
- 8K bytes (4K words) of RAM memory
- Sockets for up to 12K bytes of PROM/EPROM
- PROM-based monitor with debugging capability
- Two serial ports with programmable baud rates
- 24-line parallel port (three byte-wide ports)
- Three interval timers
- Optional PROM-based ASCII Assembler
- Interfaces for direct I/O to a CRT terminal or the 96/4016-KBD keyboard/display board
- SBC 80 physical size
- Can be used as an execution vehicle with the **AmSYS 8/8 Development System**
- Provides up-load/down-load capability with the **AmSYS 8/8 Development System**

The AmZ8000 architecture – in terms of CPU resources, instruction set, system interface and software-oriented features – represents a major advance in microprocessor sophistication and system-level performance. It is efficient enough to service simple tasks effectively, yet can easily handle complex, high-performance applications as well.

The AmZ8000 architecture and partitioning is well suited for today's technology and for a very wide range of today's applications. It is also a significant departure from the constraints of past architectures, and establishes a clean attractive and nearly open-ended base for evolution and development.

The **AMC 96/4016 Board** makes use of these features and assists software and system engineers in evaluating these features of the AmZ8000 for existing and future needs. Moreover, with the cleaner architecture of this new-generation microprocessor, the Evaluation Board can help hardware and software professionals develop better interface circuits and programs.

ABUNDANT CPU RESOURCES

The AmZ8000 offers sixteen 16-bit general-purpose registers in addition to special system registers. All 16 registers may be used as accumulators and all but one can serve as index registers. The first eight of these 16-bit registers may be used as sixteen 8-bit byte registers if needed. The AmZ8000 also supports seven main data types; bits, BCD digits, bytes, words (16 bits), long words (32 bits), byte strings and word strings. Additionally, many other data elements such as memory addresses, I/O addresses, segment table entries and program status words are also provided.

The **AMC 96/4016** gives the user access to the AmZ8000 and the ability to reduce programming overhead and shorten product and project development time. Hands-on experience with the Evaluation Board can help demonstrate the effectiveness of the AmZ8000 to provide fewer program modifications and less debug time.

Compared to other microprocessors or even 16-bit minicomputers, the number and power of individual instructions have greatly increased. Over 110 distinct instruction types are available with the AmZ8000, compared to approximately 60 for the PDP 11/45. With few exceptions, byte, word and long-word data elements can be processed by all the instructions. Each instruction – again with few exceptions – can use any of the five main addressing modes.

System designers, and especially programmers, will find the **AMC 96/4016 Board** useful in evaluating the AmZ8000's instruction set and its ability to generate higher code densities that can result in significant memory savings and shorter execution times.

HIGHER THROUGHPUT COMPILERS

Many applications normally involve high-level languages, operating systems and data-base management. The AmZ8000, with proven N-channel MOS technology and a 4MHz clock, allows the use of lower-cost dynamic RAMs. The AmZ8000 overlaps instruction execution with next instruction fetch to avoid the problems associated with deep unconditional pre-fetching.

The AmZ8000 can achieve this high degree of performance because its regular architecture does not have critical bottlenecks and because the sophisticated instruction set substantially reduces the number of instructions. Some examples of this sophistication are:

- a. 32-bit operations (including multiply and divide in single instructions)
- b. String manipulation, including compare & translate
- c. Block I/O instructions
- d. Direct addressing of the entire memory
- e. Two operating modes (systems/normal or supervisor/user)
- f. Powerful interrupt handling

The **AMC 96/4016 Evaluation Board** makes effective use of these features so designers and managers can interpret these appealing features in specific terms and assess the capability for improved systems that can be designed quicker, easier and with more efficient results.

The AmZ8000 is designed to span a wide variety of applications. It's features allow it to be used effectively in complex high-throughput systems, yet it remains efficient for simpler systems as well.

Photo showing use of the AMC 95/6440 Card Cage to house and power the 96/4016 Evaluation Board. Optional Keyboard/Display Unit shown above (or standard CRT Terminal) attaches via cable to edge-card connector. This arrangement provides both convenience and expansion capabilities for specific project and product development.

THE AmZ8000 EVALUATION BOARD NOW FOR BEST RESULTS

SPECIFICATIONS: AMC 96/4016 EVALUATION BOARD	
CPU	AmZ8000, non-segmented
Time Base	Crystal controlled; 3.9936MHz
Serial I/O	Two RS-232C serial ports with software programmable baud rates (50-9600). One port jumper selectable for 20mA operation.
Parallel I/O	24 parallel I/O lines. Also provides inter-connection to AmSYS 8/8 Development System.
RAM Memory	8K bytes of on-board dynamic memory; CPU refreshed (transparent).
PROM Space	12K bytes of PROM/ROM Space provided; six sockets; ROM monitor occupies two sockets.
Counter/Timer	Three programmable 16-bit interval counters; two counters used for baud rate control; third counter available for user programs.
Power	+12VDC; -12VDC; +5VDC
Dimensions	12.0" (305 mm) x 6.75" (172 mm); SBC 80 form factor with six edge-card connectors
Memory Mapping	ROM monitor: 0-0FFF(H) PROM space: 0-2FFF(H) RAM space: 4000-5FFF(H)
Environmental Conditions	0 to 55°C ambient in free-air space with relative humidity to 90% without condensation.
Edge-of-Card Connectors	P1: 86-Pin, for power and ground P2: 60-Pin; CPU bus P3: 50-Pin parallel I/O for up/down link as execution vehicle P4: 26-Pin; interface for optional keyboard and display P5: 26-Pin; RS-232 and counter/timer interface P6: 26-Pin; RS-232 or 20mA current loop for CRT terminal or TTY as command console.
Monitor	4K PROM monitor included
Assembler	Optional ASCII, one-pass, line assembler in EPROM
Up/Down-Load Capability	Can be plugged directly into AmSYS 8/8 Development System to provide up-load and down-load capability.
Execution Vehicle	Can be used with other computer systems to execute AmZ8000 code.
Optional Keyboard/Display	56-key keyboard; 20-character alpha-numeric LED display; same physical form as 96/4016 Board with attaching standoff connectors and interconnecting ribbon cable.

With Powerful Software Support . . .

AMC 96/4016 ROM MONITOR

The Monitor Program provides the capability to examine and change data in RAM and in any and all of the AmZ8000 registers. It features a hardware breakpoint command along with a single-step routine to provide precise monitoring and debugging capability through step-by-step execution of AmZ8000 code. Additional commands allow users to load registers from memory and execute routines. The combination of 'Breakpoint/Load/Single Step' (with display) provides a versatile and efficient debugging capability. This monitor also supports the Evaluation Board when it is used with Advanced Micro Computer's **AmSYS 8/8 Development System** as an up/down-load device through its SAVE (to disk) and LOAD (disk to RAM) commands. The monitor resides in 4K bytes of EPROM and uses two of the six ROM/EPROM sockets available on the Evaluation Board.

AMC 96/4016 ASSEMBLER

The **AMC 96/4016 Evaluation Board** is supported by a one-pass line-by-line ASCII code Assembler (AMC 96/4016-ASM). This PROM-resident assembler provides the capability to enter symbolic programs into RAM and translates mnemonic op codes, symbolic labels and symbolic or absolute operands to machine code. The assembler reads user-supplied symbolic assembly statements from the command console and assembles the statements as received. Diagnostic messages are displayed when incorrect statements are entered as well as at the end-of-assembly for unsatisfied references with associated locations. Forward references are also permitted. The assembler features:

- A set of ten special characters for syntax and definition
- Seven pseudo op codes
- Six register formats to handle various word lengths
- Six direct-addressing formats to reference counter locations, labels and strings (ASCII, decimal, hex)
- Eight diagnostic messages for errors involving syntax, system operation, duplication, overflow and undefined references.

. . . and many ways to use it

AS A STANDALONE MICROCOMPUTER

The **96/4016 Evaluation Board**, along with available options, has the capability of standalone operation. On-board resources, including RAM, I/O interfaces, monitor and interval timer, allow it to serve as a self-contained single-board computer. A terminal or optional keyboard/display can be attached as a command console. Communications to peripherals and other equipment can be achieved through the I/O ports.

EXECUTION DEVICE WITH CROSS-ASSEMBLERS

Many users will want to evaluate the AmZ8000 execution speed and throughput performance with respect to existing programs and system designs. The **AMC 96/4016** is designed to serve as a vehicle to execute AmZ8000 machine codes that may have originated from development systems and cross assemblers. I/O ports on the Evaluation Board provide the necessary parallel and serial interfaces. AmZ8000 CPU signals are brought out to an edge connector which allows the needed connection for other circuitry.

UP-LOAD/DOWN-LOAD CAPABILITY

The **AMC 96/4016 Evaluation Board** features both up-load and down-load capability when used as an execution vehicle with other computer systems, such as the AmSYS 8/8. Programs generated in a development system can be down-loaded to the RAM on the Evaluation Board. Similarly, programs in the board's RAM memory can be up-loaded to the system for further development and for disk storage.

The Evaluation Board is hardware and software compatible with Advanced Micro Computer's **AmSYS 8/8 Development System**. It can plug directly into the AmSYS 8/8 as an execution vehicle to run developed AmZ8000 code. The on-board ROM monitor provides SAVE and LOAD commands that control bidirectional data flow between the RAM on the Evaluation Board and disk files on the Development System.

The **AMC AmSYS 8/8 Development System** contains a comprehensive set of hardware and software resources to fully utilize AmZ8000 capabilities. The system contains dual floppy-disk drives, 64K bytes of RAM, serial and parallel ports, hardware computation and an SBC 80 Multi-Master bus. Existing programming support includes an operating system with linking loader, editor and debugger and, of particular interest, an AmZ8000 macroassembler, 8080 macroassembler and AmZ8000 translator. High-level languages, including PASCAL, are available. See the AmSYS 8/8 brochure for more details or contact one of the sales offices listed on the rear of this brochure.

AMC's PASCAL Compiler

7

Features

- The Compiler Runs in the AmSYS 8/8 or the AmSYS 29 Microcomputer Development Systems Environments
- Object Program may be one of the Following:
 - P-code (Executed by an Interpreter)
 - Am9080 Machine Code
 - AmZ8000 Machine Code
- Block Structured High Level Language that Supports Structured Design and Programming
- Many Extensions such as Separate Compilation, Strings, etc.

PASCAL

The AMC PASCAL compiler gives the AmSYS 8/8 user a powerful language for software development. The PASCAL language offers structured design capabilities to the user. The AMC PASCAL user can work with data of varying types and can manipulate sets, arrays, records and files with great flexibility. A large number of intrinsic functions and procedures are available to the user. In general, PASCAL provides powerful language constructs that are combined with an efficient block structure to produce PASCAL programs.

PASCAL is fast becoming a widely used language on microcomputers. The PASCAL language itself is an Algol derivative invented by Niklaus Wirth. AMC PASCAL is a PASCAL implementation with additional features that extend the capabilities for a broad range of software development.

Producing an AMC PASCAL program is a two-step process. First the source program is converted (compiled) into an intermediate pseudo code (P-code). At this point, the user has the following choice: to execute the P-code interpretively on AmSYS 8/8, or to generate native machine code for the 8080 or AmZ8000 microprocessor (see Figure 1).

Interpretive Execution

The AMC PASCAL user can compile a PASCAL program and then execute the compiled program on AmSYS 8/8 with the PASCAL interpreter and run-time library. The AMC P-code is compatible with Version 1.4 of the P-code developed at the University of California at San Diego. In this mode of execution, the interpreter in fact simulates in AmSYS 8/8 the run time environment of a P-machine which is the host hardware to which P-code is native. A run time library supports the interpreter in executing built-in functions or procedures (intrinsic) or system defined operators (see Figure 2).

Code Generation

Alternatively, the P-code generated by the compiler may be converted into object code for the 8080 or AmZ8000 microprocessors. The code generation process involved is as follows (see Figure 3). First the P-code file is translated to produce an assembly language file which can then be assembled by MACRO8 for the 8080 or MACRO8000 for AmZ8000 to produce a relocatable object module. This module contains only the user written part of the PASCAL program; all the intrinsic operators and functions are as yet undefined external subroutines at this point. These subroutines have been prewritten and preassembled, and are contained in a library file. The runtime routines in this library are then selectively combined with the user object module through a linker, generating an executable object code file.

Data Types

PASCAL is very specific about the "type" of a variable. The type defines precisely the set of values a variable may assume (its domain), which in turn indirectly determines the set of operators that may act upon it. In addition to the predefined standard types, the user may create his own types of data. A variable may also be either static or dynamic, defining storage requirement at compile time or run time respectively. With such rich data typing and data structuring facilities, the programming job becomes much easier for the user.

- Integer – A 16-bit number, $-32768 \leq n \leq 32767$
- Real – A 32-bit floating point number, $10^{-38} \leq n \leq 10^{38}$
- Boolean – True or false
- Character – Alphabets, digits, blank and some special characters
- Scalar – Domain is user program defined; this allows great flexibility in creating new data types and provides a means for a more explanatory statement of the problem
- Subrange – A proper subset of a previously defined type; increases program clarity by being very specific about the intended domain of variable
- Set – A collection of components of the same type; components in a set are also ordered
- Array – A fixed number of components arranged in consecutive order either linearly or as a multidimensional matrix; any arbitrary element may be randomly accessed directly
- File – A structure consisting of components which may be accessed sequentially
- String – A linear array of characters
- Record – A structure consisting of a fixed number of unordered components which need not be of the same type
- Pointer – A dynamic structure bounded only to a type at compile time and remains otherwise free until binding to a specific variable occurs at runtime when memory space is allocated; very useful in creating and processing data structures like linked lists and trees

Functions and Procedures

A function is a "subroutine" that returns a single value. Syntactically, a function call may appear anywhere in place of a variable within an expression. Its effect as a constituent of an expression amounts to the result value that it yields. A procedure, however, is a "subroutine" that may indirectly return more than a single value. Syntactically, it is a stand alone statement. Some common properties of both are given below:

- May be recursive, very useful in system programming
- Parameters may be passed by "value"; a parameter, possibly an expression, is evaluated at call time to a value which is bounded to the formal parameter at that time and remains unchanged
- Parameters may also be passed by "variable"; at call time, the formal parameter is bounded only to a variable, whose value does not necessarily remain constant throughout the function or procedure

Dynamic Memory Allocation

Being a block structured language, scopes of variables are limited to procedures or functions within which they are declared, and have no significance externally. As long as a procedure or function has not been activated, variables local to it need not exist. The P-code has been designed to take advantage of this fact. Memory spaces for variables are allocated on top of stack only upon a function or procedure entry, and relinquished automatically upon exit. Expression evaluation is also performed on this stack.

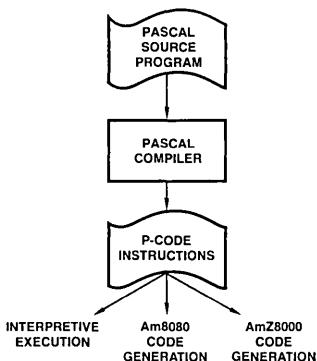

FIGURE 1. The Compilation Process.

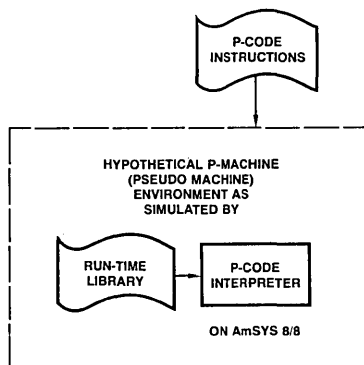

FIGURE 2. Interpretive Execution.

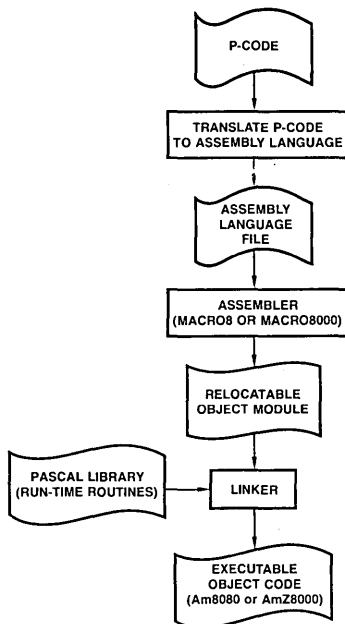

FIGURE 3. Code Generation.

FIGURE 4. Dynamic Memory Allocation.

Therefore the total memory space required for data storage dynamically expands and contracts at run time coinciding with function or procedure entries and exists, taking up memory space only as needed. This allows execution of much larger programs than would otherwise be possible.

It is also possible to dynamically create, at run-time, data structures such as lists and trees whose storage space sizes vary throughout their lifetimes. In order to avoid conflict, memory allocation for this purpose is at the opposite end of memory (heap) for optimum memory utilization. Intrinsic procedures are provided within the language for user control (MARK and RELEASE) of the heap.

AMC PASCAL Operators and Intrinsic

A summary of operators that may be used in an expression is shown in Figure 5. An intrinsic is a system defined function or procedure. A PASCAL intrinsic function is a function in the mathematical sense; its net effect is the result value yielded without any other side effects. A summary of intrinsic functions is shown in Figure 6. An intrinsic procedure produces either return values through variable parameters, or its purpose may be to produce some side effects, or it may be a combination of both. A summary of intrinsic procedures is shown in Figure 7.

Operator	Operation	Type of Operands	Result Type
Definition:			
:=	assignment	any type but files	as appropriate
Arithmetic:			
+(unary)	identity	INTEGER or REAL	same as operand
-(unary)	sign conversion	INTEGER or REAL	same as operand

Compiler Options

AMC PASCAL provides a number of compilation options for the user. The most important options are:

GOTO – PASCAL GOTO statements can be disabled within the program.

IOCHECK – Code can be added by the compiler to verify the completion of I/O Operations.

INCLUDE – Different source files can be included during the compilation process.

LISTING – Listing can be selectively disabled.

QUIET COMPILATION – Console device output during compilation can be suppressed.

RANGECHECK – Code can be added by the compiler to check array subscript range and assignment to variables of subrange types.

AMC PASCAL Extensions

AMC PASCAL has a number of extensions to the standard PASCALs defined by Jensen and Wirth. The most important extensions are:

- Separate compilation – A PASCAL program may be written in many UNITS and compiled separately one at a time. This also allows linkage of assembly language subroutines to PASCAL programs.
- Interactive files – An additional predeclared type INTERACTIVE is provided, and the files INPUT and OUTPUT are automatically typed as INTERACTIVE.
- Untyped files – The BLOCKREAD and BLOCKWRITE intrinsics are provided for read and write operations on untyped files.
- Random access – For typed files, the SEEK intrinsic provides random access to records. For untyped files BLOCKREAD and BLOCKWRITE provide random access.
- Strings – An additional predeclared type STRING is provided. The STRING type is essentially equivalent to PACKED ARRAY OF CHAR.
- EXIT – Before the normal end of any procedure or function, the user can exit with the EXIT intrinsic.
- Comparisons – The user can compare entire arrays or records with the equal and not equal operators.
- Dynamic Memory Allocation – The MARK and RELEASE intrinsics are provided instead of the DISPOSE intrinsic. MARK and RELEASE are used to set a pointer in the user heap and then release heap space from the pointer to the top of the heap.

What is PASCAL and P-Code

PASCAL is a block structured high level language with strong typing of variables. Virtues of block structured languages are much discussed and well understood. In addition, PASCAL offers rich data types that are not found in most languages. Some more notable ones are: set, scalar, structured array and record, and dynamic pointer. This allows data structures to be constructed both statically and dynamically making the language a very useful tool not only at the application level, but at the systems programming level as well. The major strength of PASCAL, however, lies in the fact that it is a powerful language even with a relatively few number of basic constructs. This is attributed significantly to its powerful and flexible data types. As a result, PASCAL has gained the following advantages: easy to learn, simple to program, straight-forward to compile, efficient object code, fast execution, program clarity, self documenting and easy to maintain.

Being a block structured language, it lends itself to efficient execution on a host CPU with a stack architecture. Instructions of a stack machine typically require zero operand specification since they are implicitly assumed to be on top of the stack. As a result, the instructions are very compact.

A companion part to the language definition of PASCAL itself is just such a pseudo machine level instruction set (called P-code) for a hypothetical pseudo stack machine (P-machine). The instruction set has been tailor designed to represent PASCAL programs very compactly and concisely.

Due to this well defined transformation from PASCAL statements to P-code instructions, a compiler can be written very efficiently to generate P-code instructions from PASCAL source programs. Execution of a PASCAL program via its P-code equivalent can then be done in one of two ways. It can be either executed in its native P-machine environment as simulated by a software interpreter, or alternatively, P-code instructions may be translated into native instructions of host CPUs such as Am9080 or AmZ8000 to be executed.

The AMC PASCAL is upward compatible with that developed at the University of California at San Diego both at the source program level and at the P-code level. It includes a number of extensions to the standard PASCAL to enhance its usefulness in the microcomputer environment where hardware resources are more directly controlled by programmer at a lower level.

AMC's MACRO8000

AmZ8000 Macro Assembler

Features

- Functions in the AmSYS 8/8 or AmSYS 29 microcomputer development system environments
 - Generates absolute or relocatable AmZ8000 object code
 - Supports the full AmZ8000 instruction set
 - Symbolic operands that are constants or variables
 - Syntactic macros
 - Program segmentation for address space control
 - Arithmetic expressions, string expressions, and comparisons
 - Superior assembly speed and a variety of assembly options
-

The AMC MACRO8000 assembler gives the AmSYS 8/8 or AmSYS 29 user a dynamic way to develop AmZ8000 code for any application. A typical MACRO8000 program is a combination of AmZ8000 assembly instructions and higher-level constructs. MACRO8000 provides great flexibility in structuring the program and in fine-tuning to produce the most efficient AmZ8000 code for the application.

Assembler Output Format

MACRO8000 produces an output file of either absolute or relocatable AmZ8000 code. The user can choose to write absolute or relocatable code for either the nonsegmented AmZ8002 or segmented AmZ8001 processor. An absolute source program is monolithic in structure, and the program is assembled as a single unit. The output from the assembler can be an object file which can be loaded into the target system for the execution. A modular source program is relocatable and the user can choose to write separate modules or routines that are later merged into a coherent program. A linking procedure handles the merging of the program components and produces a single relocatable file containing the program modules linked together. A loading procedure assigns absolute addresses to a relocatable file and loads the resulting object file into memory for subsequent execution in the target system.

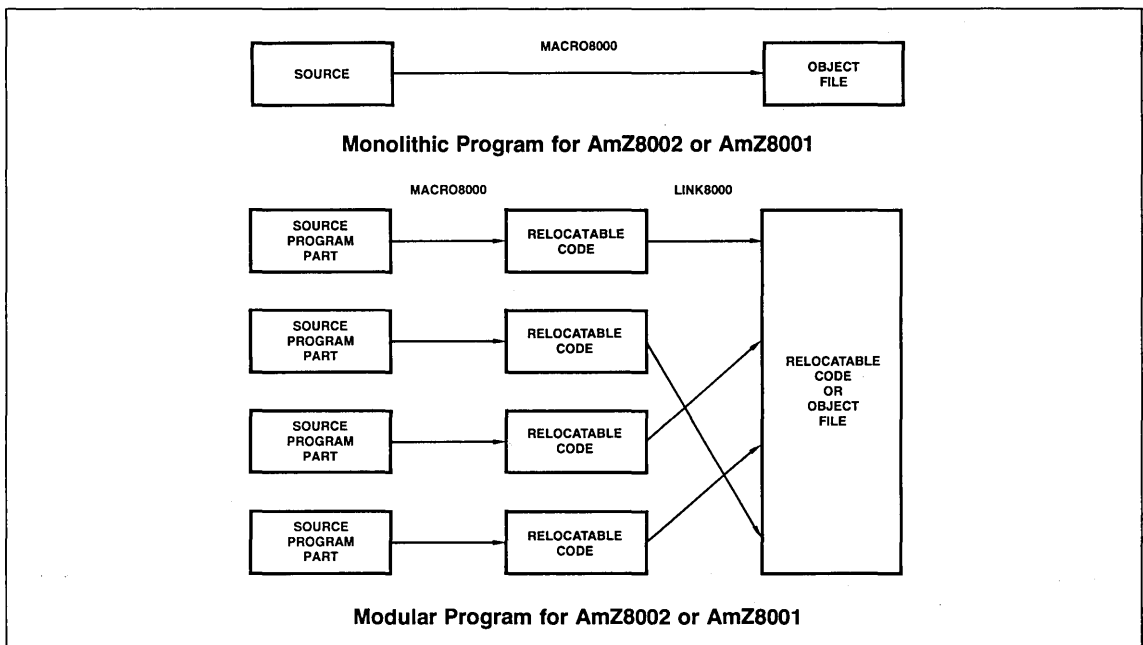

Instruction Format

The full AmZ8000 instruction set can be used in writing programs. The general format of an instruction is the opcode (instruction mnemonic such as ADD) followed by the operands. MACRO8000 generates the appropriate bit pattern for each instruction, which is 1 to 5 words in length. The user can specify whatever operands are appropriate for the instruction. AmZ8000 instructions have from zero to four operands, and the operands can be in various addressing modes.

Addressing Modes

The AmZ8000 addressing modes are for different types of operands and are supported through the hardware. The addressing modes give the user great flexibility in choosing whether an operand is directly or indirectly specified to be in a register, in memory or in part of the instruction.

- The immediate mode specifies an operand which is a constant imbedded within the instruction itself.
- The register mode specifies an 8-bit (byte) register, 16-bit (word) register, 32-bit (long word) register, or 64-bit (quad word) register that contains the operand value.
- The indirect register mode specifies a word register (nonsegmented AmZ8002) or register pair (segmented AmZ8001) that contains the address of the operand.
- The direct address mode specifies a label. The label is associated with the address of a data value that is used as the operand, or the label is associated with an instruction to which a jump or call instruction branches to.
- The relative address mode specifies an operand whose location is found relative to the present instruction location.
- The indexed mode is a directly addressed operand followed by a displacement that is in a register. The label and displacement added together forms the address of the operand value.
- The base address mode consists of an indirect register specification followed by a displacement. The address of the operand is calculated by adding together the content of the register and the displacement value.
- The base indexed mode is a register indirect address specification followed by a displacement that is in another register. The address of the operand is calculated by adding together the contents of the two specified registers.

AMC's MACRO8000

- The port immediate mode consists of a port address for I/O operations that is specified as a 16-bit immediate value.
- The port register mode specifies a register that contains a 16-bit port address for I/O operations.

Opcodes

The AmZ8000 instruction opcodes are the names for the individual instructions. The naming scheme involves a few characters for the basic name of the instruction, such as LD for load, and sometimes additional characters that specify other properties of the instruction. For instance, LDIRB is a Load with auto Increment and Repeat for Byte operands. Well over 200 different opcodes can be written.

- CLR – Clear (byte, word or long word)
- EX – Exchange (byte or word)
- LD – Load (byte, word, or long word; special form for multiple registers; special form for addresses; optional autoincrement or autodecrement; optional repeat)
- POP and PUSH – Pop and Push stack (word or long word)
- ADD – Add (byte, word, or long word; optionally with carry)
- CP – Compare (byte, word, or long word; optional autoincrement or autodecrement; optional repeat)
- DAB – Decimal adjust (byte)
- DEC – Decrement (byte or word)
- DIV – Divide (word or long word dividend)
- EXTS – Extend sign (byte, word or long word)
- INC – Increment (byte or word)
- MULT – Multiply (word or long word result)
- NEG – Negate (byte or word)
- SUB – Subtract (byte, word, or long word; optionally with carry)
- AND – Logical AND (byte or word)
- COM – Complement (byte or word)
- OR – Logical OR (byte or word)
- TEST – Logical test (byte, word, or long word)
- TCC – Test condition code (byte or word)
- XOR – Exclusive OR (byte or word)
- R – Rotate (left or right; special form for digit; optionally through carry; byte or word)
- S – Shift (left or right; optionally dynamic; arithmetic or logical; byte, word, or long word)
- BIT – Bit test (static or dynamic; byte or word)
- RES – Reset bit (static or dynamic, byte or word)
- SET – Set bit (static or dynamic, byte or word)
- TSET – Test and set (byte or word)
- CPS – Compare strings (autoincrement or autodecrement; optional repeat; byte or word)
- TR – Translate (autoincrement or autodecrement; optional repeat; byte)
- TRT – Translate and test (autoincrement or autodecrement; optional repeat; byte)
- IN – Input (optional autoincrement or autodecrement; optional repeat; optional special input; byte or word)
- OUT – Output (optional autoincrement or autodecrement; optional repeat; optional special output; byte or word)
- CALL – Call routine (normal or relative)
- RET – Return
- JP – Jump (normal or relative)
- DJNZ – Decrement and jump on non-zero (byte or word)
- SC – System call
- INRET – Interrupt return

- COMFLG, RESFLG, SETFLG – Flag complement, reset, or set
- DI, EI – Interrupt disable or enable
- HALT – Halt
- NOP – No operation
- MBIT, MRES, MSET, MREQ – Multi-micro test, reset, set, or request
- LDCTL – Load control (flag byte or special control word)
- LDPS – Load program status

High Level Constructs

MACRO8000 offers a variety of high-level constructs that can be used in assembler programs. High-level constructs make most programs easier to write, simpler to debug and maintain than functionally-equivalent programs containing only instructions. The constructs in MACRO8000 are either very similar or identical to PASCAL statements. Programmers familiar with PASCAL or another block-structured language will be comfortable with the MACRO8000 high-level constructs.

- IF-THEN-ELSE is for conditional assembly, or for run-time code generation. A test such as register equal to register generates code.
- FOR-DO is for repetitive assembly.

Symbolic Operands

MACRO8000 supports symbolic constants and symbolic variables. The values of symbolic constants and variables are essentially any operands that can be used in the program, including arithmetic expressions. The symbolic constants are names used for constant values. This provides for the assignment of meaningful names such as BLOCK_COUNT to a register used as the block count. The symbolic variables are defined and then throughout the program can be redefined to new values such as different registers. All of the evaluation of the variables occurs at assembly time, so that the generated code reflects the values substituted for the symbolic constants and variables.

Syntactic Macros

The macro capability allows the programmer to reduce the amount of source code that must be written. Identical or similar sections of code can be prepared as a macro and called out as appropriate. During assembly the call is replaced by the code of the macro body. The macros in MACRO8000 are internally processed as syntactic macros, which are assembled at up to over an order of magnitude faster than the conventional lexical macros.

Program Segmentation

The MACRO8000 relocatable module system is based on the concept of "segment" meaning "a piece or part of a program." Thus, a "program" may be defined as a collection or sequence of program segments. Named program segments may be assigned attributes, and arranged and combined in any arbitrary manner by LINK8000. This simple unifying concept applies to both the AmZ8001 and AmZ8002 CPUs. In the case of the AmZ8001 (segmented CPU), program segments may be identified with (i.e., equated to) logical segments. Program segmentation has many uses beyond the specification of logical segments for the AmZ8001 – for example, the partitioning of program space into RAM space and ROM space.

LINK8000 offers simple default modes of operation for the novice user. For more advanced users, LINK8000 offers incremental linking, providing an enhanced program segment mapping capability.

Expressions

The ability to write expressions often reduces the work involved in writing programs and helps to keep the programs smaller.

- Arithmetic expressions can be written to produce 32-bit signed results.
- Arithmetic signed or unsigned comparisons can be written to yield true or false values for logical tests.
- Strings can be used and concatenated in string expressions.
- String comparisons can be used to compare strings by collating sequence and yield true or false values for logical tests.

Assembly Options

In addition to fast assembly, with one pass through the source and a second pass for the listing, MACRO8000 offers a variety of options.

- Option to suppress first pass listing.
- Option to direct listing to the console, to the printer, to a default file, or to a user-specified file. The listing shows the source program, any diagnostic messages produced by the assembler, and the AmZ8000 code and data values generated by the program.
- Option for error messages only, and option to suppress warning messages.
- Option for macro trace that displays code expansion.
- Option for object file generation.

Linker

The LINK8000 linker is a separate module used for linking together relocatable modules of any size. The linker can bring in library routines to satisfy external references. The user can control the mapping of modules into the object file, as well as the mapping of user segments within modules. LINK8000 can also handle relative address references across segments. Output of the linker is an object file that can be run on either the nonsegmented AmZ8002 or the segmented AmZ8001.

Advanced Micro Devices Commitment to Excellence

**Product Assurance Programs for Military
and Commercial Integrated Circuits**

A

A COMMITMENT TO EXCELLENCE

Advanced Micro Devices was conceived on the premise that there was a place in the semiconductor community for a manufacturer dedicated to excellence.

In product assurance procedures, Advanced Micro Devices is unique. Only Advanced Micro Devices processes all integrated circuits, commercial as well as military, to the demanding requirements of MIL-STD-883. The Rome Air Development Center (RADC), which is the Air Force's principal authority on component reliability, has issued MIL-HDBK-217B which indicates that parts processed to Military Standard 883, Level C (Advanced Micro Devices' standard processing) yield a product nearly ten times better in failure rates than the industry commercial average.

Our Sunnyvale facility has been certified by the Defense Electronics Supply Center (DESC) to produce parts to JAN Class B and C under Military Specification MIL-M-38510. The National Aeronautics and Space Administration (NASA) has certified this production line for the manufacture of Class A products for programs requiring the highest levels of reliability. Advanced Micro Devices is the only integrated circuit company formed within the last ten years to achieve such line certification.

This brochure outlines Advanced Micro Devices' standard programs for Class B, C and A devices for military and commercial operating range applications. These will cover the majority of system requirements today. Alternative screening flows for specific user needs can be performed on request. Check with your local sales office for further information.

ADVANCED MICRO DEVICES' STANDARD PRODUCTS ARE MANUFACTURED TO MIL-STD-883 REQUIREMENTS

Advanced Micro Devices' product assurance programs are based on two key documents.

MIL-M-38510 – General Specification for Microcircuits

MIL-STD-883 – Test Methods and Procedures for Microelectronics

The screening charts in this brochure show that every integrated circuit shipped by Advanced Micro Devices receives the critical screening procedures defined in MIL-STD-883, Method 5004 for Class C product. This includes molded plastic devices.

In addition, documentation, design, processing and assembly workmanship guidelines are patterned after MIL-M-38510 specifications.

Commercial and industrial users receive the quality and reliability benefits of this aerospace-type screening and documentation at no additional cost.

STANDARD PRODUCT TESTING CATEGORIES

Advanced Micro Devices offers integrated circuits to four standard testing categories.

1. Commercial operating range product (typically 0°C to 70°C)
2. Commercial product with 100% temperature testing
3. Military operating range product (typically -55°C to +125°C)
4. JAN qualified product

Categories 1, 2 and 3 are available on most Advanced Micro Devices circuits. Category 4 is offered on a more limited line. Check with your local sales office for details.

STANDARD PRODUCT ASSURANCE CATEGORIES

Devices produced to the above testing categories are available to the three standard classes of product assurance defined by MIL-STD-883. As a minimum, every device shipped by Advanced Micro Devices meets the screening requirements of Class C.

Class C – For commercial and ground-based military systems where replacement can be accomplished without difficulty.

According to MIL-HDBK-217B, this assures relative failure rates 9.4 times better than that of regular industry commercial product.

Class B – For flight applications and commercial systems where maintenance is difficult or expensive and where reliability is vital.

Devices are upgraded from Class C to Class B by burn-in screening and additional testing.

According to MIL-HDBK-217B, Class B failure rate is improved 30 times over regular industry commercial product. Advanced Micro Devices Class B processing conforms to MIL-STD-883 requirements. MIL-HDBK-217B indicates that this may provide failure rates as much as two times better than some other manufacturers' "equivalent" or "pseudo" Class B programs.

Class S – For space applications where replacement is extremely difficult or impossible and reliability is imperative.

Class S screening includes x-ray and other special inspections tailored to the specific requirements of the user.

The 100% screening and quality conformance testing performed within these Advanced Micro Devices programs is shown in TABLES I, II and III. A full description of the process flow is provided in Product Assurance Document 15-010, available on request.

CLASS C SCREENING FLOW FOR COMMERCIAL SYSTEMS AND GROUND BASED MILITARY SYSTEMS

**TABLE I
CLASS C
INTEGRATED CIRCUITS**

Screening Procedure per MIL-STD-883 Method 5004, Class C		COMMERCIAL OPERATING RANGE		MILITARY OPERATING RANGE	
		HERMETIC AND MOLDED PACKAGES		HERMETIC PACKAGE ONLY

**TABLE II
GROUP A QUALITY CONFORMANCE LEVELS**

Advanced Micro Devices employs the military-recommended LTPD sampling system to assure quality. MIL-STD-883, Method 5005, TABLE I, Group A, subgroups 1 through 9 as appropriate to the device family are performed on every lot. Quality levels defined for Class B product are applied by Advanced Micro Devices to both Class B and Class C orders.

	LTPD	INITIAL SAMPLE SIZE
Subgroup 1 – Static tests at 25°C	5	45
Subgroup 2 – Static tests at maximum rated operating temperature	7	32
Subgroup 3 – Static tests at minimum rated operating temperature	7	32
Subgroup 4 – Dynamic tests at 25°C – LINEAR devices	5	45
Subgroup 5 – Dynamic tests at maximum rated operating temperature – LINEAR devices	7	32
Subgroup 6 – Dynamic tests at minimum rated operating temperature – LINEAR devices	7	32
Subgroup 7 – Functional tests at 25°C	5	45
Subgroup 8 – Functional tests at maximum and minimum rated operating temperatures	10	22
Subgroup 9 – Switching tests at 25°C – DIGITAL devices	7	32
Subgroup 10 – Switching tests at maximum rated operating temperatures – DIGITAL devices	*	
Subgroup 11 – Switching tests at minimum rated operating temperatures – DIGITAL devices	*	

*These subgroups, where applicable, are usually performed during initial characterization only for all except JAN Qualified product.

CLASS B SCREENING FLOW FOR HIGH RELIABILITY COMMERCIAL AND MILITARY SYSTEMS

**TABLE III
CLASS B
INTEGRATED CIRCUITS
(Class C plus burn in screening
and additional testing.)**

Screening Procedure per MIL-STD-883 Method 5004, Class B		COMMERCIAL OPERATING RANGE		MILITARY OPERATING RANGE

	Group B	-	-	(4)	Sample
	Group C	-	-	(4)	Sample
	Group D	-	-	(4)	Sample
EXTERNAL VISUAL	2009 (Note 5)	100%	100%	100%	100%

Notes: 1. Not applicable to molded packages.

2. All MOS RAMs and many other MOS devices receive a.c. testing and 100% d.c. screening at high temperature and power supply extremes as standard. Other products sampled at Group A (Table III).

3. Tested at high temperature, 100°C, only on commercial range product. Note that this is a full d.c. check of all parameters in addition to the simple "hot-rail" functional sequence performed on most other commercial programs.

4. Available to special order.

5. Without optical aid for commercial devices. *Unless otherwise specified on the device data sheet.

CLASS S FOR AEROSPACE SYSTEMS. (FORMERLY CLASS A)

Advanced Micro Devices offers a Class S program.

This program together with other high reliability screening options, such as SEM and x-ray, is described as Option A in Advanced Micro Devices' Extended Processing Options Document 00-003. Contact your local Advanced Micro Devices' sales office for more information.

STANDARD PRODUCT SCREENING SUMMARY AND ORDERING INFORMATION

1. COMMERCIAL PRODUCT

- Screened per MIL-STD-883, Method 5004.
- Electrically tested per AMD Data Sheet.
- Supplied in hermetic and molded packages.
- Quality conformance testing, Method 5005, Group A, performed to levels specified for Class B on both Class C and Class B options.

Class C (Flow C1)

- Order standard AMD part number.
- Marked same as order number.
Example: Am2901ADC

Class B (Flow B1)

- Burn in performed in AMD circuit condition.
- Order standard AMD part number, add suffix B (or /883B for 1, 2 and 300 Series Linear devices).
- Marked same as order number.
Example: Am2901ADC-B

3. MILITARY PRODUCT

- Screened per MIL-STD-883, Method 5004.
- Electrically tested per AMD Data Sheet.
- Supplied in hermetic package only.
- Quality conformance testing, Method 5005, Group A, performed to levels specified for Class B on both Class B and Class C options.

Class C (Flow C3)

- Order standard AMD part number.
- Marked same as order number.
Example: Am2901ADM

Class B (Flow B3)

- Burn in performed in AMD circuit condition.
- AC at 25°C, dc and functional testing at 25°C as well as temperature and power supply extremes performed on 100% of every lot.
- Quality conformance testing, Method 5005, Groups B, C and D available to special order.
- Order standard AMD part number, add suffix B.
- Marked same as order number.
Example: Am2901ADM-B

2. COMMERCIAL PRODUCT WITH 100% TEMPERATURE TESTING

- Identical to standard commercial operating range product with the addition of 100% dc and functional testing at 100°C and power supply extremes.

Class C (Flow C2)

- Order standard AMD part number, add suffix T.
- Marked same as order number.
Example: Am2901ADC-T

Class B (Flow B2)

- Burn in performed in AMD circuit condition.
- Order standard AMD part number, add suffix TB.
- Marked same as order number.
Example: Am2901ADC-TB

4. JAN QUALIFIED PRODUCT

- Screened per MIL-STD-883, Method 5004.
- Electrically tested to JAN detail specification (slash sheet).
- Manufactured in Defense Logistics Agency certified facility.
- Quality conformance testing, Method 5005, Groups A, B, C and D performed as standard and must be completed prior to shipment.
- It is a product for which AMD has gained QPL listing.*

Class C (Flow C4)

- Order per military document.
- Marked per military document.
Example: JM38510/44001CQB

Class B (Flow B4)

- Burn in performed in circuit condition approved for JAN devices.
- Order per military document.
- Marked per military document.
Example: JM38510/44001BRC

*In certain cases where JAN Qualified product is specified but is not available, Advanced Micro Devices can provide devices to the electrical limits and burn-in criteria of the slash sheet. This class of product has been called JAN Equivalent and marked M38510/ by some manufacturers. This identification is no longer permitted by DESC. Check with your local sales office for availability of specific device types.

Standard Lead Finish	b		c		c		c		c		c		c	

Notes: 1. Lead finish b is tin plate. Finish c is gold plate.
 2. Dimensions E₁ and D₁ allow for off-center lid, meniscus, and glass overrun.

PRODUCT ASSURANCE

MIL-M-38510 • MIL-STD-883

The product assurance program at Advanced Micro Devices defines manufacturing flow, establishes standards and controls, and confirms the product quality at critical points. Standardization under this program assures that all products meet military and government agency specifications for reliable ground applications. Further screening for users desiring flight hardware and other higher reliability classes is simplified because starting product meets all initial requirements for high-reliability parts.

The quality standards and screening methods of this program are equally valuable for commercial parts where equipment must perform reliably with minimum field service.

Two military documents provide the foundation for this program. They are:

MIL-M-38510 – General Specification for Microcircuits

MIL-STD-883 – Test Methods and Procedures for Microelectronics

MIL-M-38510 describes design, processing and assembly workmanship guidelines for military and space-grade integrated circuits. All circuits manufactured by Advanced Micro Devices for full temperature range (-55°C to $+125^{\circ}\text{C}$) operation meet these quality requirements of MIL-M-38510.

MIL-STD-883 defines detail testing and inspection methods for integrated circuits. Three of the methods are quality and processing standards directly related to product assurance:

Test Method 2010 defines the visual inspection of integrated circuits before sealing. By confirming fabrication and assembly quality, inspection to this standard assures the user of reliable circuits in long-term field applications. Standard inspection at Advanced Micro Devices includes all the requirements of the latest revision of Method 2010, condition B.

Test Method 5004 defines three reliability classes of parts. All must receive certain basic inspection, preconditioning and screening stresses. The classes are:

Class C – Used where replacement can be readily accomplished. Screening steps are given in the AMD processing flow chart.

Class B – Used where maintenance is difficult or expensive and where reliability is vital. Devices are upgraded from Class C to Class B by 160-hour burn-in at 125°C followed by more extensive electrical measurements. All other screening requirements are the same.

Class S – Used where replacement is extremely difficult and reliability is imperative. Class S screening selects extra reliability parts by expanded visual and X-ray inspection, further burn-in, and tighter sampling inspection.

All hermetically sealed integrated circuits (military and commercial) manufactured by Advanced Micro Devices are screened to MIL-STD-883, Class C. Molded integrated circuits receive Class C screening except that centrifuge and hermeticity steps are omitted.

Optional extended processing to MIL-STD-883, Class B is available for all AMD integrated circuits. Parts procured to this screening are marked with a “-B” following the standard part number, except that linear 100, 200 or 300 series are suffixed “/883B”.

Test Method 5005 defines qualification and quality conformance procedures. Subgroups, tests and quality levels are given for Group A (electrical), Group B (mechanical quality related to the user’s assembly environment), Group C (die related tests) and Group D (package related tests). Group A tests are always performed; Group B, C and D may be specified by the user.

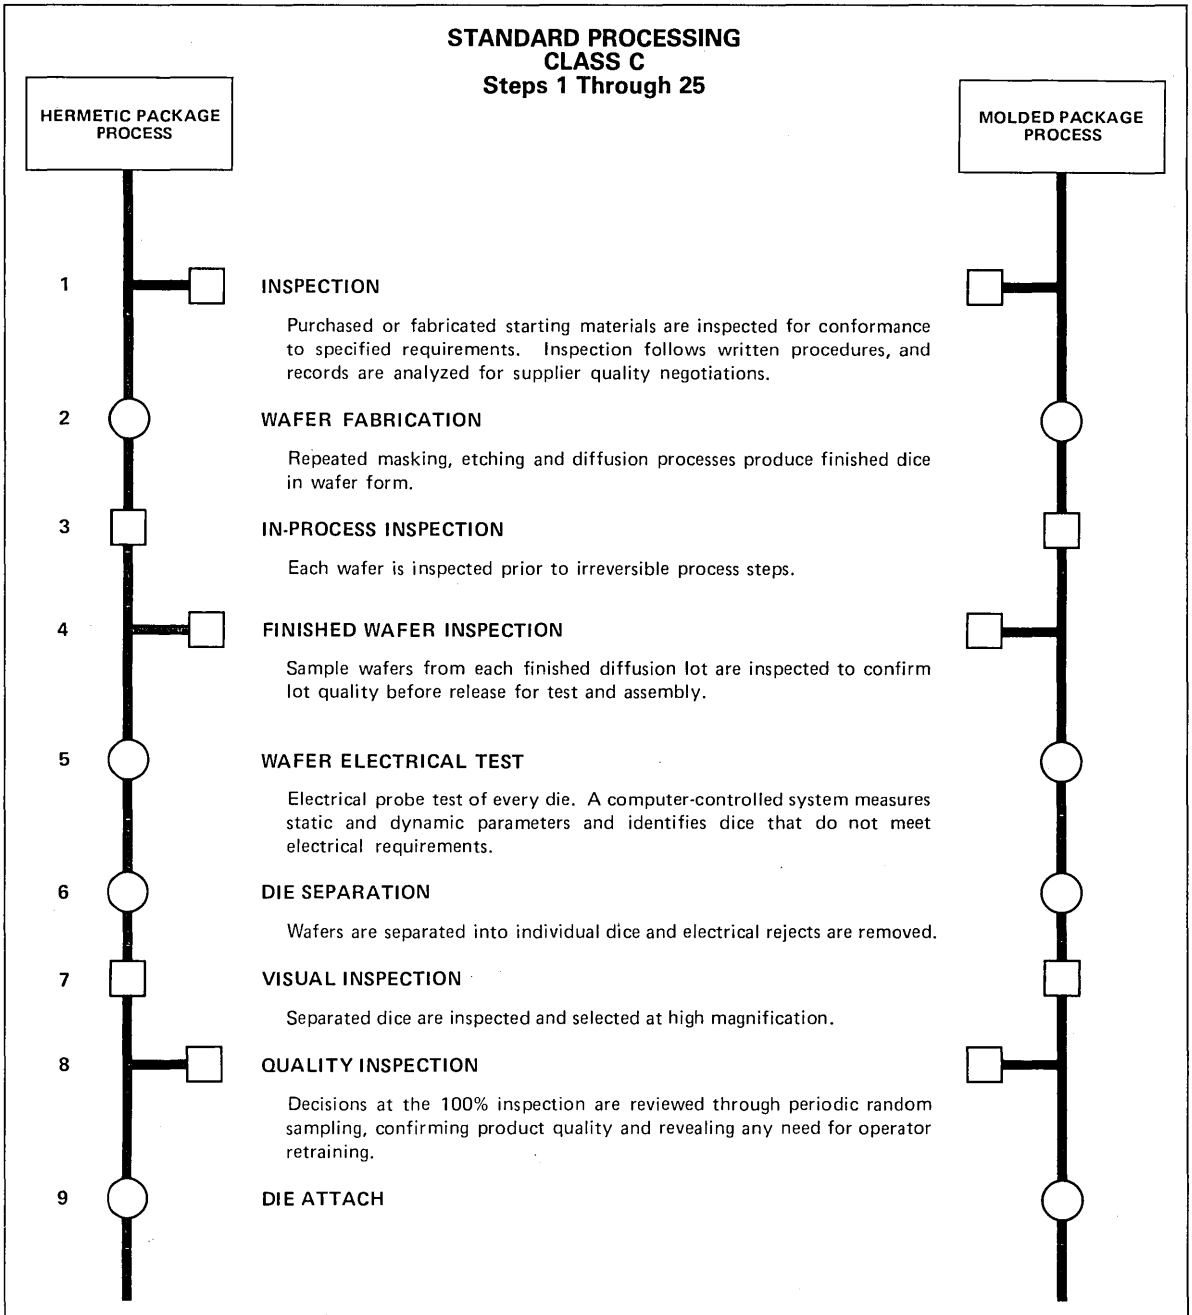

Product Assurance

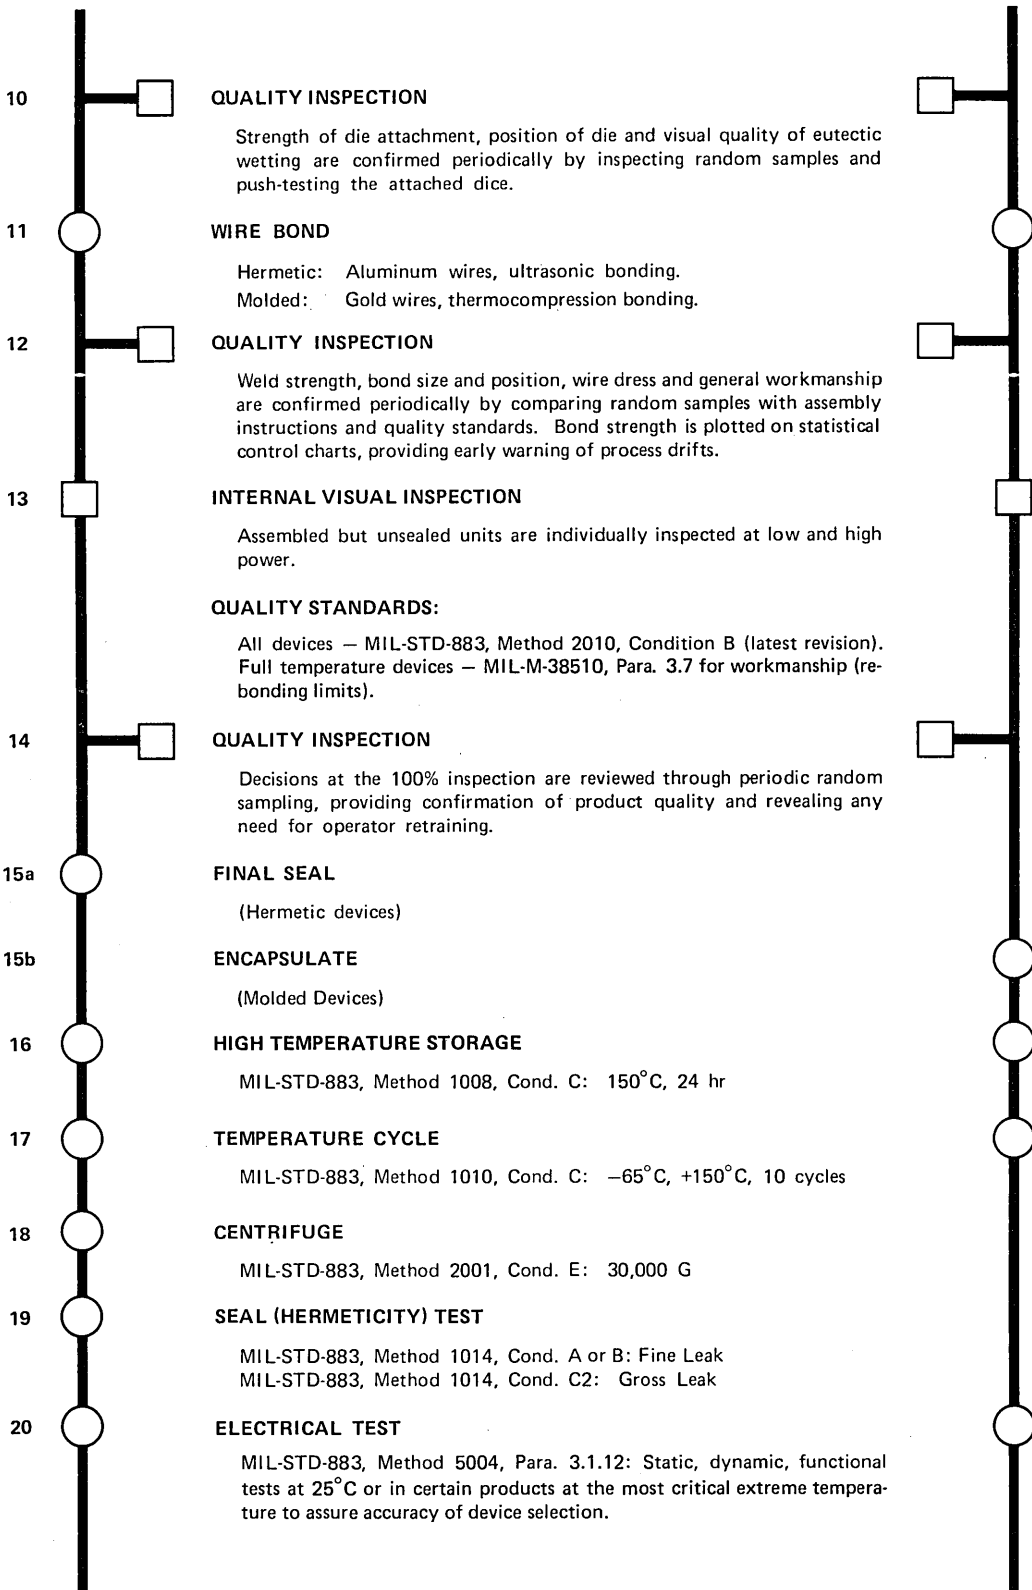

**MANUFACTURING, SCREENING AND INSPECTION
FOR
INTEGRATED CIRCUITS**

All integrated circuits are screened to MIL-STD-883, Method 5004, Class C; quality conformance inspection where required is performed to Class B quality levels on either Class B or Class C product.

All full-temperature-range (-55°C to +125°C) circuits are manufactured to the workmanship requirements of MIL-M-38510.

The flow chart identifies processing steps as they relate to MIL-STD-883 and MIL-M-38510.

QUALITY INSPECTION

Strength of die attachment, position of die and visual quality of eutectic wetting are confirmed periodically by inspecting random samples and push-testing the attached dice.

WIRE BOND

Hermetic: Aluminum wires, ultrasonic bonding.
Molded: Gold wires, thermocompression bonding.

QUALITY INSPECTION

Weld strength, bond size and position, wire dress and general workmanship are confirmed periodically by comparing random samples with assembly instructions and quality standards. Bond strength is plotted on statistical control charts, providing early warning of process drifts.

INTERNAL VISUAL INSPECTION

Assembled but unsealed units are individually inspected at low and high power.

QUALITY STANDARDS:

All devices – MIL-STD-883, Method 2010, Condition B (latest revision).
Full temperature devices – MIL-M-38510, Para. 3.7 for workmanship (re-bonding limits).

QUALITY INSPECTION

Decisions at the 100% inspection are reviewed through periodic random sampling, providing confirmation of product quality and revealing any need for operator retraining.

FINAL SEAL

(Hermetic devices)

ENCAPSULATE

(Molded Devices)

HIGH TEMPERATURE STORAGE

MIL-STD-883, Method 1008, Cond. C: 150°C, 24 hr

TEMPERATURE CYCLE

MIL-STD-883, Method 1010, Cond. C: -65°C, +150°C, 10 cycles

CENTRIFUGE

MIL-STD-883, Method 2001, Cond. E: 30,000 G

SEAL (HERMETICITY) TEST

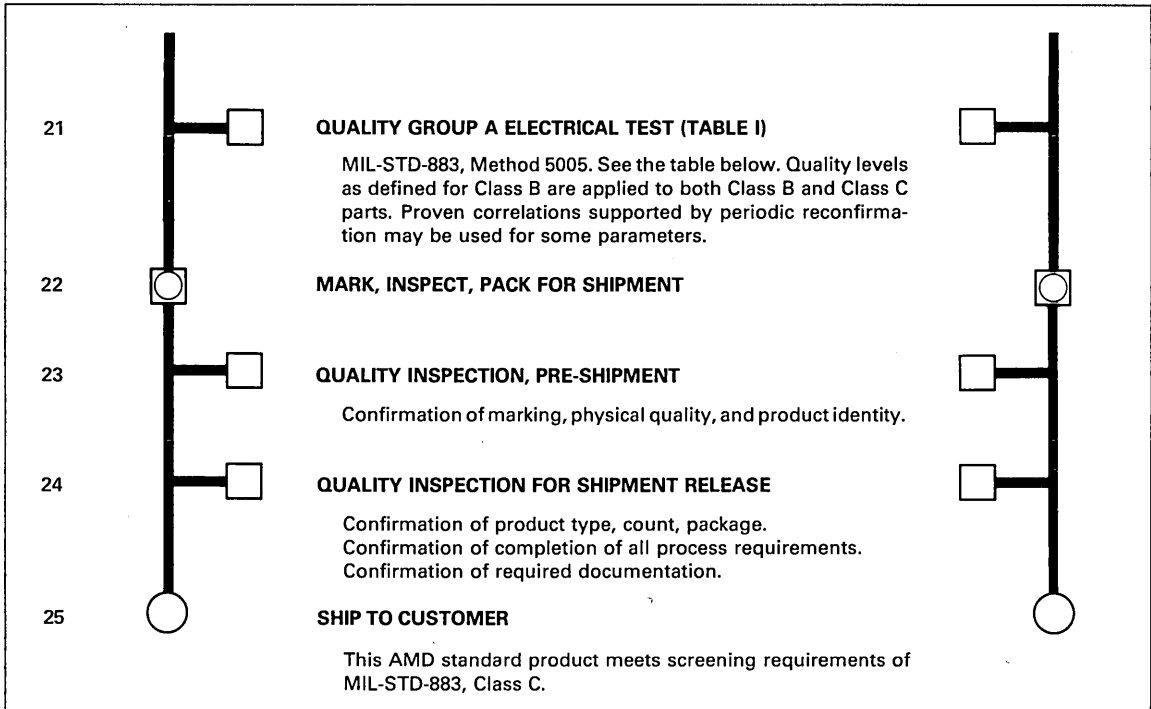

MIL-STD-883, Method 1014, Cond. A or B: Fine Leak
MIL-STD-883, Method 1014, Cond. C2: Gross Leak

ELECTRICAL TEST

MIL-STD-883, Method 5004, Para. 3.1.12: Static, dynamic, functional tests at 25°C or in certain products at the most critical extreme temperature to assure accuracy of device selection.

Product Assurance

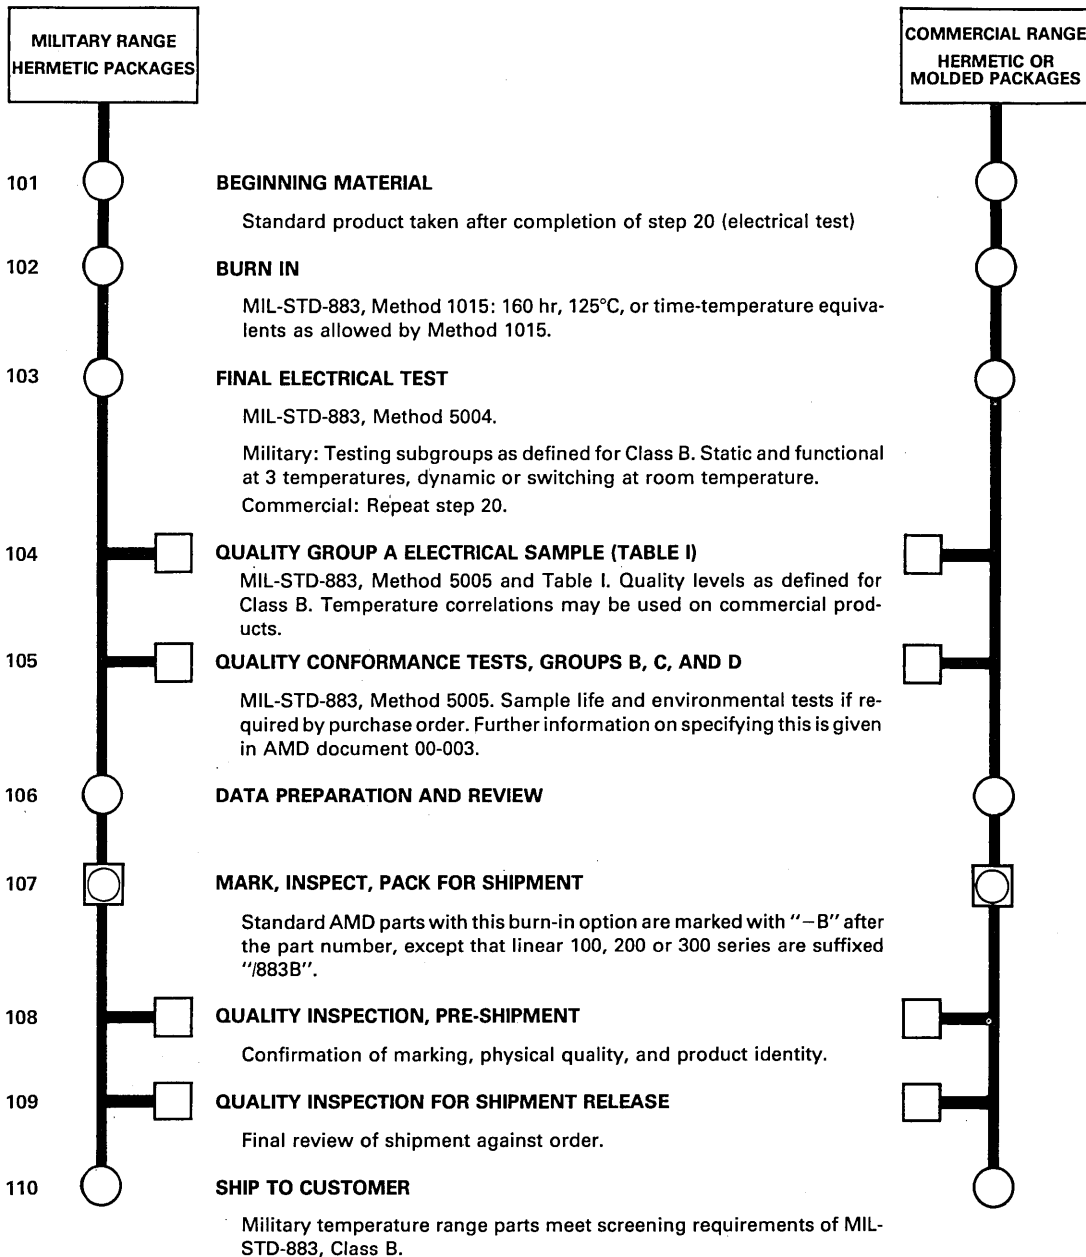

GROUP A ELECTRICAL TESTS
From MIL-STD-883, Method 5005, Table I

Subgroups	LTPD (Note 1)	Initial Sample Size
Subgroup 1 – Static tests at 25°C	5	45
Subgroup 2 – Static tests at maximum rated operating temperature	7	32
Subgroup 3 – Static tests at minimum rated operating temperature	7	32
Subgroup 4 – Dynamic tests at 25°C – Linear devices	5	45
Subgroup 5 – Dynamic tests at maximum rated operating temperature – Linear devices	7	32
Subgroup 6 – Dynamic tests at minimum rated operating temperature – Linear devices	7	32
Subgroup 7 – Functional tests at 25°C	5	45
Subgroup 8 – Functional tests at maximum and minimum rated operating temperatures	10	22
Subgroup 9 – Switching tests at 25°C – Digital devices	7	32
Subgroup 10 – Switching tests at maximum rated operating temperature – Digital devices (Note 2)	10	10
Subgroup 11 – Switching tests at minimum rated operating temperature – Digital devices (Note 2)	10	10

1. Sampling plans are based on LTPD tables of MIL-M-38510. The smaller initial sample size, based on zero rejects allowed, has been chosen unless otherwise indicated. If necessary, the sample size will be increased once to the quantity corresponding to an acceptance number of 2. The minimum reject number in all cases is 3.
2. These subgroups are usually performed during initial device characterization only.

OPTIONAL EXTENDED PROCESSING CLASS B Steps 101 Through 110

Advanced Micro Devices offers several extended processing options to meet customer high-reliability requirements. These are defined in AMD document 00-003. The flow chart below outlines Option B, a 160-hr burn in. Military temperature range devices processed to this flow (in the left column) meet the screening requirements of MIL-STD-883, Class B.

OTHER OPTIONS

Document 00-003, "Extended Processing Options", further defines Option B as well as other screening or sampling options available or special order. Available options are listed here for reference.

Option	Description	Effect
A	Modified Class A screen (Similar to Class S screening)	Provides space-grade product, following most Class S requirements of MIL-STD-883, Method 5004.
B	160-hr operating burn in	Upgrades a part from Class C to Class B.
X	Radiographic inspection (X-ray)	Related to Option A. Provides limited internal inspection of sealed parts.
S	Scanning Electron Microscope (SEM) metal inspection	Sample inspection of metal coverage of die.
V	Preseal visual inspection to MIL-STD-883, Method 2010, Cond. A	More stringent visual inspection of assemblies and die surfaces prior to seal.
P	Particle impact noise (PIN) screen with ultrasonic detection.	Detects loose particles of approximately 0.5 mil size or larger, which could affect reliability in zero-G or high vibration applications.
Q	Quality conformance inspection (Group B, C and D life and environmental tests)	Samples from the lot are stressed and tested per Method 5005. The customer's order must state which groups are required. Group B destroys 16 devices; Group C, 92 devices; Group D, 60 devices.
