NCCN Guidelines Version 4.2019
Prostate Cancer

- **Footnote m was modified: Men with low or favorable intermediate risk disease may consider the use of the following tumor-based molecular assays: Decipher, Oncotype DX Prostate, Prolaris, and ProMark.**

Retrospective studies have shown that molecular assays performed on prostate biopsy or radical prostatectomy specimens provide prognostic information independent of NCCN *or CAPRA* risk groups. These include, but are not limited to, likelihood of death with conservative management, likelihood of biochemical progression after radical prostatectomy or external beam therapy, and likelihood of developing metastasis after radical prostatectomy or salvage radiotherapy. See Discussion.

Improving Risk Stratification

HEALTH

Prostate Cancer Surgery or Not?

Genomics tests help doctors figure out which patients can follow 'active surveillance' and which ones need treatment

BY LUCETTE LAGNADO

IN 37 YEARS as a police officer, Edwin Michel coped with a plane crash, a sniper, wildfires and three bullet wounds.

Nothing much rattled him until he was diagnosed with prostate cancer in November 2016. His doctor said the cancer wouldn't kill him but Mr. Michel, now 76 years old, wasn't entirely reassured.

He felt more confident after a genomics test later revealed his prostate cancer was very low risk. The test, known as Oncotype DX, takes a sample from a prostate biopsy and analyzes 17 genes in it to

RY FOR THE WALL STREET JOURNAL; MICHIGAN PHOTOGRAPHY

Sleuthing Out Sickness

Deaths from prostate cancer have decreased due to better treatments and early detection, doctors say. At the same time the number of cases has fallen, which many attribute to a decline in screening.

Example of Internet DTCA

The CyberKnife Treatment Advantage

CyberKnife surgery is completely non-invasive and has transformed radiosurgeries of the brain, prostate gland, breast, spine and soft-tissue (lungs, liver, pancreas and kidneys) into painless, bloodless outpatient procedures. Patients who undergo CyberKnife treatment typically resume normal activities soon after the procedure.

With high-tech, cruise-missile-guidance technology and ultra-flexible, computer-controlled robotics, CyberKnife delivers extraordinarily accurate, precisely targeted radiation to tumors throughout the body when radiation therapy is indicated. The beams can be sculpted to reach small, deeply embedded, complex masses, minimizing damage to healthy tissue.

CyberKnife surgery advantages include:

- Treatment for tumors inoperable by conventional surgery or other stereotactic radiosurgery.
- Additional treatment option for tumors that have received maximum allowed radiation.
- Painless, bloodless and non-invasive.
- High-dose radiation delivered accurately.
- Ability to treat multiple tumors at different locations during a single session.
- Healthy tissue unharmed.
- No need for invasive, uncomfortable head frame or skull pins.
- Usually no more than five treatments of 35 minutes each.
- Full-body treatment capability CyberKnife is cleared by the FDA for treatment of tumors and lesions anywhere in the body when radiation therapy is indicated. However, patients should consult their physicians to determine if this treatment approach is right for them.

AUA-FDA-SUO PARTIAL GLAND ABLATION FOR PROSTATE CANCER WORKSHOP MAY 2015

Jim Kiefert: “ablate the cancer cells within the gland and still maintain the safety of your gland, seems like a promise from heaven, something that we would really -- every man would like to have happen….

The guys who have chosen to have active surveillance, many of them really dread the biopsies…

Our hope is that the men with low-risk cancer would say…I would go on active surveillance, but I would much rather have partial ablation than to have the full gland either surgically removed or radiated or frozen….

American Urological Association & U.S. Food & Drug Administration. Public Workshop – American Urological Association-Food and Drug Administration-Society of Urologic Oncology Workshop on Partial Gland Ablation for Prostate Cancer, May 17, 2015.

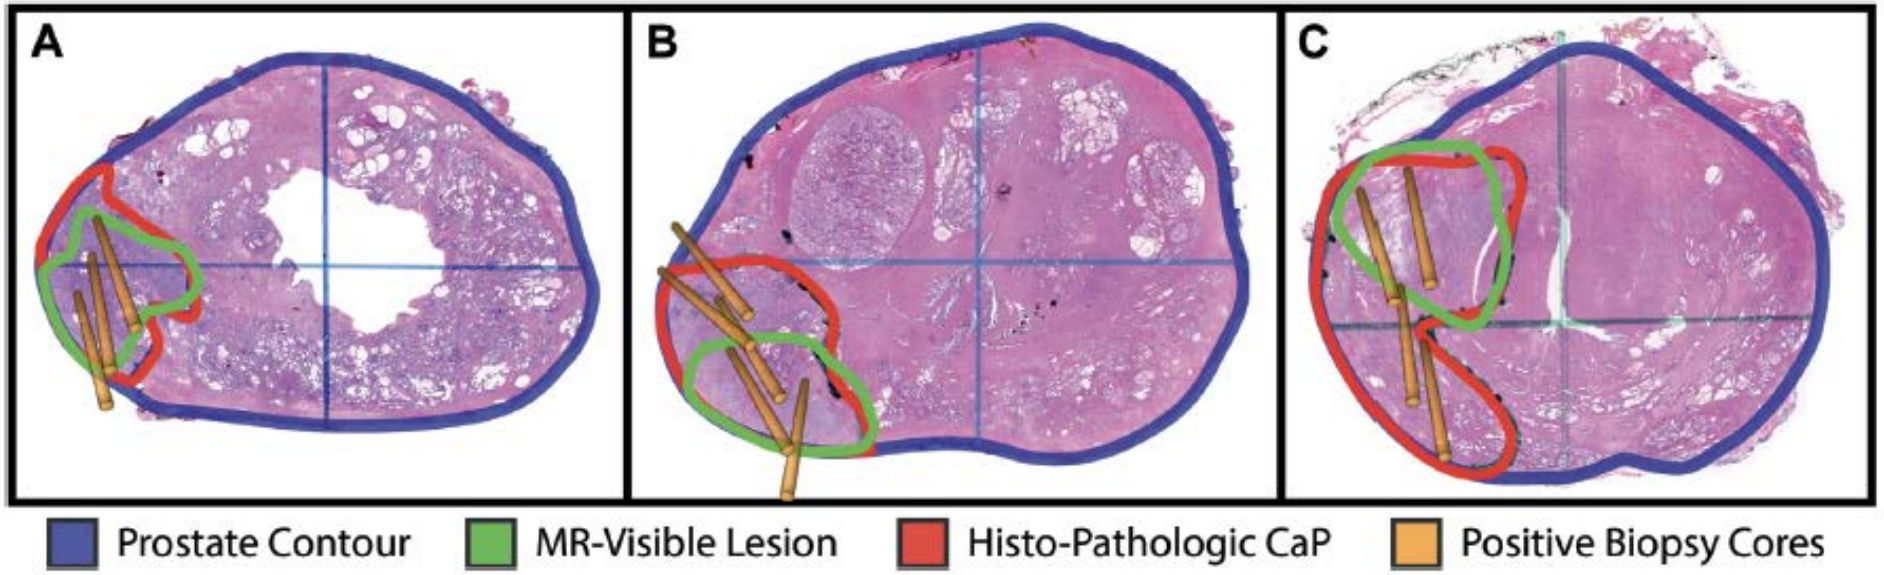
Focal Therapy Eligibility Determined by Magnetic Resonance Imaging/Ultrasound Fusion Biopsy

Nima Nassiri,* Edward Chang,* Patricia Lieu, Alan M. Priester, Daniel J. A. Margolis, Jiaoti Huang, Robert E. Reiter, Frederick J. Dorey, Leonard S. Marks and Shyam Natarajan†

From the Department of Urology, David Geffen School of Medicine (NN, EC, PL, RER, FJD, LSM) and Department of Bioengineering (AMP), University of California-Los Angeles (SN), Los Angeles, California, Department of Radiology, Weill Cornell at New York Presbyterian (DJAM), New York, New York, and Department of Pathology, Duke University School of Medicine (JH), Durham, North Carolina



Using intermediate risk eligibility criteria, 39% of men with a targeted biopsy proven lesion identified on MRI would have been *eligible for focal therapy*. Eligibility determined by *fusion biopsy was concordant with whole mount histology* in 75% of cases. Improved selection criteria are needed to reliably determine focal therapy eligibility

Nassiri N, Chang E, Lieu P, et al. Focal Therapy Eligibility Determined by Magnetic Resonance Imaging/Ultrasound Fusion Biopsy. J Urol. 2018 Feb;199(2):453-458. doi: 10.1016/j.juro.2017.08.085. Epub 2017 Aug 19.

Extensive Histological Sampling following Focal Therapy of Clinically Significant Prostate Cancer with High Intensity Focused Ultrasound

Use of MRI-Guided Biopsy for Selection and Follow-up of Men Undergoing Hemi-gland Cryoablation of Prostate Cancer

Steve R. Zhou, Demetrios N. Simopoulos, Rajiv Jayadevan, Ely R. Felker, Merdie K. Delfin, Danielle E. Barsa, Lorna Kwan, and Leonard S. Marks

OBJECTIVE To investigate safety, efficacy, and quality of life impact of hemi-gland cryotherapy for clinically-significant prostate cancer (CaP), when patient selection and follow-up includes MRI-guided biopsy.

METHODS Twenty-nine men with unilateral CaP (all clinically significant with prostate volume <60 cc) were enrolled in a prospective observational trial of hemi-gland cryotherapy. Mean patient age was 68.7 years. Median prostate-specific antigen (PSA) was 6.6 ng/mL. MRI-guided biopsy (3T-MRI, Artemis US fusion) was used for diagnosis and repeated at 6-month follow-up in all men. Treatment was under general anesthesia using the BTG/Galil system. Validated questionnaires were used to determine effects of treatment on urinary and sexual function and quality of life.

RESULTS Cryotherapy was completed satisfactorily in all 29 cases in <60 minutes with no intraoperative complications. Significant decreases in PSA (median decrease 5.6 ng/mL) and PSA density (median decrease 0.14 ng/mL/cc) were observed ($P < .01$). At 6 months, 23 patients (79%) demonstrated no residual cancer on follow-up MRI-guided biopsy of the treated side. Three patients (10%) revealed micro-residual disease. Three patients (10%) had residual cancer and underwent further treatment. Ipsilateral MRI lesions were present before treatment in 26 patients and after treatment in only 2, reflecting the gross ablative effect; however, MRI showed disappearance of lesions in 4 patients with residual tumor on biopsy. The single complication was 1 case of transient urinary retention; 85% of men who were sexually active continued without change after treatment. Voiding function was unchanged.

CONCLUSION Hemi-gland cryoablation for clinically-significant CaP is well-tolerated, and when patients are selected and followed by MRI/US fusion biopsy, cancer control appears promising at 6 months.

6-month IPSI-LATERAL Targeted and Systematic Biopsies Performed, Mean 10 (range 4-16)

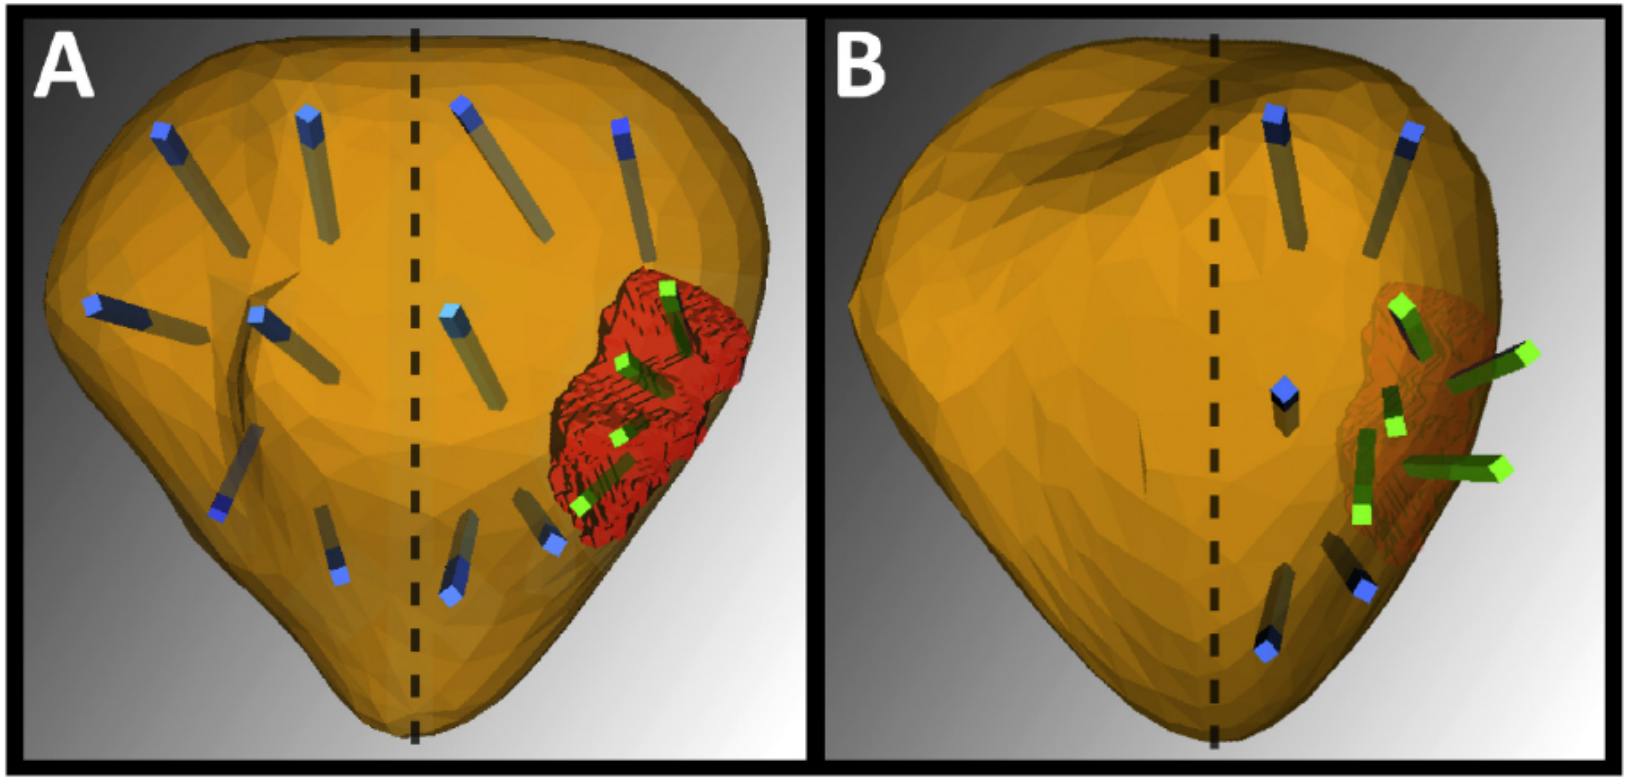

Figure 1. Illustration of biopsy method: (**A**), baseline and (**B**) 6-months after successful hemi-gland ablation. Before treatment (**A**) patient has an MRI-visible lesion on the left (red spot). Targeted cores taken from the lesion (shown in green) were found to contain csCaP. Systematic cores (blue) were found to contain no csCaP outside the lesion, making the patient eligible for focal therapy. After hemi-gland ablation (**B**), biopsy cores are guided by MRI/US fusion tracking to the region of the prior positive spots; the lesion, which was seen previously, has receded. All cores are now negative for cancer, both targeted and systematic ipsilaterally. In this study of hemi-gland ablation, 6-month biopsy samples were taken from the treated side of the prostate (see text).

Prostate Multiparametric Magnetic Resonance Imaging Features Following Partial Gland Cryoablation

Bashir Al Hussein Al Awamlh, Daniel J. Margolis, Michael D. Gross, Shyam Natarajan, Alan Priester, Stefanie Hectors, Xilu Ma, Juan Miguel Mosquera, Joseph Liao, and Jim C. Hu

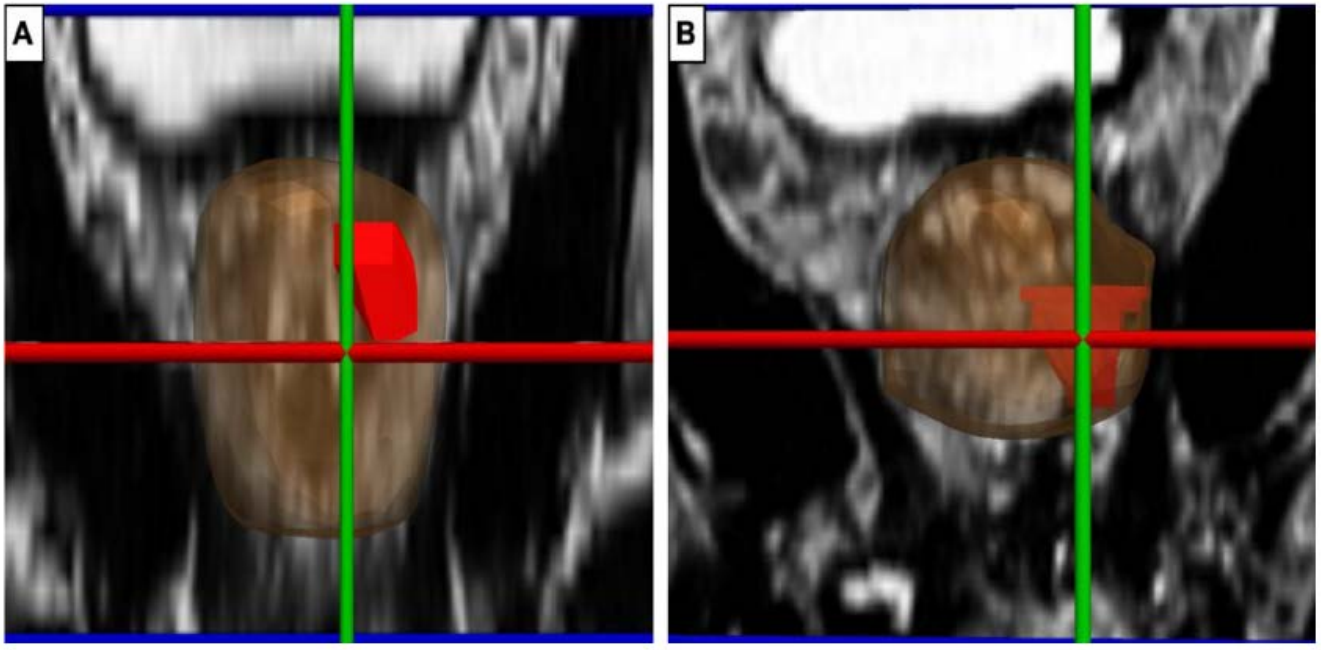

Figure 1. Pre- and post-treatment multiparametric MRI reformatted images of the prostate and region of interest. The figure shows reformatted (**A**) pretreatment (gland size 43 mL) and (**B**) post-treatment (gland size 28 mL) T2 multiparametric MRI coronal images for subject 4. The red is the target (region of interest) and the brown is the prostate. The cross hairs in the 2 images show the center of the image as acquired. In reference to the prostate, the bladder lies superiorly and the obturator muscles (which are black) laterally. (Color version available online.)

Trial design example shows how patients would be randomized to AS vs AS plus focal intervention and follow standard biopsy and clinical followup surveillance. Objective pathological and clinical progression criteria would be established to support primary end point. Key secondary end point would be reduction in number of patients who proceed to curative external beam radiation therapy (*EBRT*) or radical prostatectomy (*RP*). Safety and tolerability would be measured throughout and continue into postmarketing requirement followup.

Can we deliver randomized trials of focal therapy in prostate cancer?

Randomized Controlled Trial of Barbed Polyglyconate Versus Polyglactin Suture for Robot-Assisted Laparoscopic Prostatectomy Anastomosis: Technique and Outcomes

Stephen B. Williams[a,1], Mehrdad Alemozaffar[a,1], Yin Lei[a], Nathanael Hevelone[b], Stuart R. Lipsitz[b], Blakely A. Plaster[a], Jim C. Hu[a,b,]*

Technique and outcomes of bladder neck intussusception during robot-assisted laparoscopic prostatectomy: A parallel comparative trial

Hung-Jui Tan, M.D.[a,b], Siwei Xiong, M.D.[b], Aaron A. Laviana, M.D.[b], Ryan J. Chuang, B.S.[b], Eric Treat, M.D.[b], Patrick C. Walsh, M.D.[c], Jim C. Hu, M.D., M.P.H.[b,d,*]

Surgery in Motion

Technical Refinement and Learning Curve for Attenuating Neurapraxia and Improving Sexual Function Outcome During Robot-Assisted Radical Prostatectomy

M. Alemozaffar[a], A. Duclos[b], N.D. Hevelone[b], S.R. Lipsitz[b], T. Borza[a], H.Y. Yu[a], K.J. Kowalczyk[c], J.C. Hu[d,]*

Surgery in Motion

Posterior, Anterior, and Periurethral Surgical Reconstruction of Urinary Continence Mechanisms in Robot-assisted Radical Prostatectomy: A Description and Video Compilation of Commonly Performed Surgical Techniques

André N. Vis[a,], Henk G. van der Poel[b], Annebeth E.C. Ruiter[a], Jim C. Hu[c], Ashutosh K. Tewari[d], Bernardo Rocco[e], Vipul R. Patel[f], Sanjay Razdan[g], Jakko A. Nieuwenhuijzen[a]*

Stepwise Description and Outcomes of Bladder Neck Sparing During Robot-Assisted Laparoscopic Radical Prostatectomy

David F. Friedlander, Mehrdad Alemozaffar, Nathanael D. Hevelone, Stuart R. Lipsitz and Jim C. Hu*

Surgery in Motion

Stepwise Approach for Nerve Sparing Without Countertraction During Robot-Assisted Radical Prostatectomy: Technique and Outcomes

Keith J. Kowalczyk[a], Andy C. Huang[a], Nathanael D. Hevelone[b], Stuart R. Lipsitz[b], Hua-yin Yu[a], William D. Ulmer[a], Joshua R. Kaplan[a], Sunil Patel[a], Paul L. Nguyen[c], Jim C. Hu[a,b,]*

Can we deliver randomized trials of focal therapy in prostate cancer?

Hashim U. Ahmed, Viktor Berge, David Bottomley, William Cross, Rakesh Heer, Richard Kaplan, Tom Leslie, Chris Parker, Clare Relton, Richard Stephens, Matthew R. Sydes, Lindsay Turnbull, Jan van der Meulen, Andrew Vickers, Timothy Wilt, Mark Emberton and the Prostate Cancer RCT Consensus Group

Ahmed, H. U. *et al. Nat. Rev. Clin. Oncol.* **11**, 482–491 (2014); published online 22 April 2014; corrected online 12 September 2017; doi:10.1038/nrclinonc.2014.44

Table 1 | Abandoned trials of focal therapy in localized prostate cancer*

Trial (years open)	Location (number of centres)	Study design	Primary outcome(s)	Accrual (actual/ expected)	Accrual rate (patients per year)	Reason for closure
CROP (2011–2013)[88]	UK (>10)	Whole-gland cryotherapy vs expectant management with delayed hormones	Metastases	7/540	7	Lack of physician equipoise Patient choice
START (2007–2011)[59]	USA, Canada and UK (~16)	Active surveillance vs radical prostatectomy or radical radiotherapy	Disease-specific survival	180/2,130	43	Lack of physician equipoise Patient choice
LOPERA (2010–2011)[60,61]	UK (4)	Laparoscopic radical prostatectomy vs robot-assisted radical prostatectomy vs open radical prostatectomy	Feasibility of recruitment	28/75	35	Lack of physician equipoise Patient choice
SABRE (2009–2011)[62]	UK (5)	Low-dose-rate brachytherapy vs radical prostatectomy	Feasibility of recruitment	0/400	NA	Lack of physician equipoise Patient choice
SPIRIT (2002–2004)[63,64]	USA and Canada (31)	Brachytherapy vs radical prostatectomy	Overall survival; Metastasis-free survival and probability of survival without symptoms; Adverse effects	56/1,980	24	Lack of physician equipoise Patient choice
University of Calgary (1997–2003)[65,66]	Canada (1)	Whole-gland cryotherapy vs external-beam radiotherapy	No evidence of disease progression at 36 months (radiological, biochemical, further treatment) (non-inferiority)	244/480	40	Lack of physician equipoise Patient choice
University of Western Ontario (NR)[67]	Canada (1)	Whole-gland cryotherapy vs external-beam radiotherapy	Biopsy; Biochemical disease-free survival; Disease-specific and overall survival	64/150	NR	Change in radiotherapy practice
SWOG-8890 (1990–1992)[68]	USA (NR)	Radical prostatectomy vs external-beam radiotherapy	Overall and disease-specific survival	6/1,128	3	Lack of physician equipoise Patient choice
Northwest Uro-Oncology Group (1999–2000)[69]	UK (2)	Radical prostatectomy vs radical radiotherapy	Feasibility	1 (Target NR)	1	Lack of physician equipoise Patient choice
MRC PR06 (1994–1996)[70]	Europe (NR)	Radical prostatectomy vs radical radiotherapy	Overall survival	35/1,800	17	Lack of physician equipoise Patient choice
SPCG-10 (NR)[71]	Scandinavian countries (NR)	Radical prostatectomy vs radical radiotherapy	Overall survival	0 (Target NR)	NA	Abandoned due to poor accrual

Value (Outcomes/Cost) Based Care

VIEWPOINT

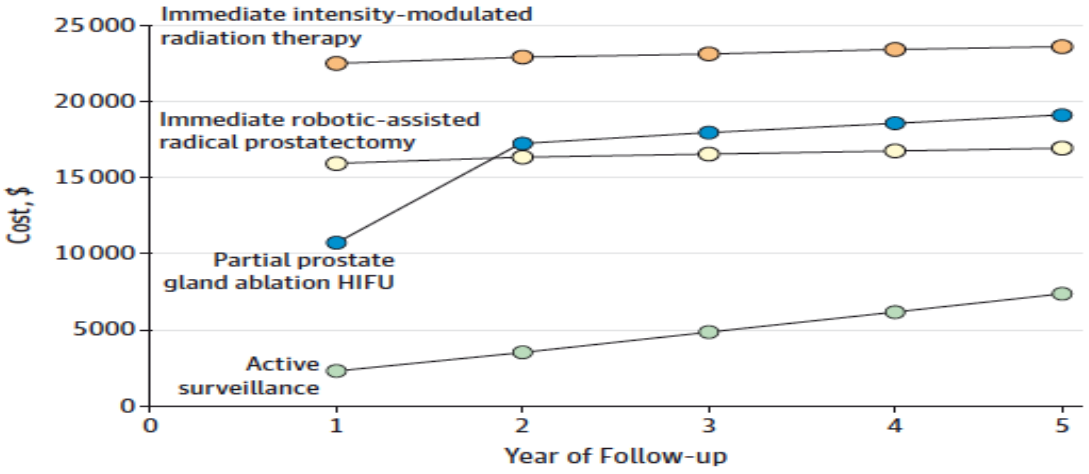
INNOVATIONS IN HEALTH CARE DELIVERY

High-Intensity Focused Ultrasound for Prostate Cancer
Novelty or Innovation?

JAMA June 28, 2016 Volume 315, Number 24

Figure. Examples of Estimated Comparative Costs of High-Intensity Focused Ultrasound Partial Gland Ablation



Costs modeled assuming 50% failure and progression and crossover to definitive therapy with intensity-modulated radiotherapy, through 5 years of follow-up. Costs for active surveillance and high-intensity focused ultrasound (HIFU) include preoperative multiparametric magnetic resonance imaging (mp-MRI) followed by annual mp-MRI and repeat biopsy as well as biannual prostate-specific antigen (PSA) testing and office visits. Biannual PSA testing and office visits are also modeled in surgery and radiotherapy costs.

Conclusions

- Elevated PSA - prostate MRI to assess risk
- TREXIT – shift to transperineal biopsy
- Precision medicine and MRI as biomarkers to improve risk stratification
- Increased use of SBRT (fewer fractions)
- Challenges of partial gland ablation
    - Patient selection
    - Follow-up endpoints
- Challenges to conduct a RCT for part gland abl.
