Release 5

Seventh Edition (September, 1979)

This edition, as amended by technical newsletters LN20-9345 and LN20-9390, applies to Release 5, Modification 0 of OS/VS Sort/Merge, Program Product 5740-SM1, and to any subsequent releases until otherwise indicated in new editions or technical newsletters. Technical newsletter LN20-9329 is obsolete.

The changes for this edition are summarized under "Summary of Amendments." Specific changes are indicated by a vertical bar to the left of the change. These bars will be deleted at any subsequent republication of the page affected. Editorial changes that have no technical significance are not noted.

Changes are periodically made to the information herein; before using this publication in connection with the operation of IBM systems, consult the latest IBM System/370 and 4300 Processors Bibliography, GC20-0001, for the editions that are applicable and current.

It is possible that this material may contain reference to, or information about, IBM products (machines and programs), programming, or services that are not announced in your country. Such references or information must not be construed to mean that IBM intends to announce such IBM products, programming, or services in your country.

Publications are not stocked at the address given below; requests for IBM publications should be made to your IBM representative or to the IBM branch office serving your locality.

A form for reader's comments is provided at the back of this publication. If the form has been removed, comments may be addressed to IBM Corporation, P.O. Box 50020, Programming Publishing, San Jose, California, U.S.A. 95150. IBM may use or distribute whatever information you supply in any way it believes appropriate without incurring any obligation to you.

SUMMARY OF AMENDMENTS
FOR LY33-8042-6
5740-SM1

RELEASE 5, MODIFICATION 0

- Improved performance when sorting variable-length records with new disk sorting technique (VLR-Blockset).
- Ability to add to or change installed or passed user options, using the new OPTION control statement.
- Support of the IBM 3375 direct access storage device for initial input, final output, and intermediate work data sets.
- Ability to produce statistical data about sort applications executed via the System Management Facility (SMF).
- Ability to specify that format CH be translated the same as format AQ.
- Ability to specify that record counters should or should not be checked at the end of execution of sorting applications that use the E35 exit routine without a SORTOUT data set.

SUMMARY OF AMENDMENTS
FOR LY33-8042-6
5740-SM1

RELEASE 4

- A further standard disk sorting technique (Blockset) added to improve performance
- The design point is changed from 32K bytes to 48K bytes
- SORTIN/SORTOUT I/O handling is enhanced to improve performance.
- The default printing of the Sort specially formatted dump is removed.
- Support of the IBM 3380 direct access storage device for initial input, final output, and intermediate work data sets.

SUMMARY OF AMENDMENTS
FOR LY33-8042-5
5740-SM1

RELEASE 3

NEW DISK SORTING TECHNIQUE

A new technique, Vale, has been introduced. Its primary function is to extend the benefits of the Peerage technique to variable-length records.

WORK DATA SETS

- The sort program's work data sets can be on a mixture of any of the supported disk types.
- If necessary, a secondary storage allocation is

automatically made; this need not be specified in JCL.

- Unused space is automatically released; this need not be specified in JCL.
- Work I/O handling has been changed to give improved performance.

LONGER INPUT RECORDS FOR DISK SORT

Input records can be up to 32,760 bytes long, regardless of whether work data sets are on tape or disk.

Preface

This publication describes the functions and internal logic of the OS/VS Sort/Merge Program Product, Program Number 5740-SM1. Its purpose is to aid IBM Program Service Representatives to understand the program and to locate and fix program faults. The reader should be familiar with the information contained in related publications listed below.

This publication has six major parts:

Section 1. Introduction describes the program's structure and operational and physical characteristics and relates it to the operating system.

Section 2. Method of Operation contains method-of-operation diagrams and extended descriptions which detail the program's functions and relate them to specific code modules.

Section 3. Program Organization gives the physical organization of the program in main storage, as well as describing the interface between modules, and record movement.

Section 4. Directories serves as a cross-reference between parts of the program and their description in the manual.

Section 5. Data Areas gives the layout of important data areas used by the program.

Section 6. Debugging Aids gives diagnostic and debugging hints under twelve headings, including how to decide whether a problem is due to a program error, how to add a temporary change to a program module, the origin of error messages, and how to effect simple bypasses.

This publication also contains four appendixes:

Appendix A. Program Exits

Appendix B. Format Codes (Conventional Techniques)

Appendix C. Checkpoint/Restart Facility

Appendix D. Program Listing Standards and Conventions

Section 1. Introduction

The OS/VS Sort/Merge Program Product has three standard components:

- Disk sort, which is reenterable
- Tape sort
- Merge only

In addition it contains two conventional disk sorting techniques, normally not used.

The total program is a generalized sort/merge program working as a processing program under the operating system. It can sort one VSAM or QSAM data set, and can merge up to 16 VSAM or QSAM data sets. Each of the QSAM data sets may consist of a number of concatenated data sets, up to the system maximum.

Input and output may be fixed or variable length, blocked or unblocked, and may be on any device supported by QSAM or VSAM. Output may be in VSAM form even if input is QSAM, as long as the output data set has previously been defined using the AMS utility.

Most sorting applications need intermediate (work) storage, which may be on:

- 2400 or 3400 series tapes
- 2314 or 2319 direct access devices
- 3330 series direct access devices (3330/3333, Model 1 and/or Model 11)
- 3340 direct access devices
- 3350 direct access devices
- 3375 direct access devices
- 3380 direct access devices
- 3380 direct access devices and 3880 Models 2 or 3 with Speed Matching Buffer
- 3380 direct access devices and 3880 Model 13 with Cache
- 3850 MSS volumes

Direct access device types can be mixed.

Relationship to the Operating System

The program communicates through macro instructions and interruptions with the operating system control program.

For example, for input and output the data management EXCP, QSAM, BSAM, or VSAM routines can be used; the EXCP (or EXCPVR, SVS, and VS1 only) macro instruction is used for intermediate storage I/O operations, and sometimes for input and output (EXCPVR is never used for input or output); and the linkage editor may be called to link-edit user-written routines to the program.

The program is designed to make use of the following facilities if they are included at system generation: Input/Output Recovery Management Support; Multiple Console Support; and (at the user's request) Checkpoint/Restart.

Program Structure

The program operates in four major phases, as indicated in Figure 1.

The first part of Phase 0 will be covered here. This part reads and interprets program control statements, and selects the technique to be used.

For a merge, there is only one technique.

TAPE SORT TECHNIQUES

If tape is specified for work areas, one of the conventional tape sorts (BALN, POLY, or OSCL) is used. The choice of technique depends solely on the numbers of work and input tapes specified.

DISK SORT TECHNIQUES

There are four standard disk sorting techniques available to the sort/merge program:

- FLR-Blockset--fixed-length records
- VLR-Blockset--variable-length records
- Peerage--fixed-length records
- Vale--both fixed- and variable-length records

Sort/merge will select one of the Blockset techniques if all the conditions for its use are met (see "Conditions for Use of Blockset Sorting Techniques").

Disk Sorting Techniques For Fixed-Length Records

The sort/merge program's most efficient fixed-length record technique, FLR-Blockset, will be used for most sorting applications, providing the conditions listed in "Conditions for Use of Blockset Techniques" are met. If one or more of the conditions for the FLR-Blockset technique are not met, the Peerage or Vale technique will be used, where possible.

Disk Sorting Techniques For Variable-Length Records

The high-performance VLR-Blockset technique will be used for sorting variable-length records if all the requirements listed in the following section are fulfilled. If not, the current variable-length disk sorting technique, Vale, will generally be used.

To enable sort/merge to attempt to select the best technique, whether VLR-Blockset or Vale, the following guidelines may be useful. If the average length of variable records is more than 350 bytes, you should specify the L5 operand on the RECORD control statement. If you specify an L5 operand that is between 350 and 1,000 bytes, Sort uses the Vale technique when the ratio of region size to number of records is large. When L5 is greater than 1,000 bytes, Vale is generally used. If the

working storage is less than 100K bytes, sort/merge will attempt to select VLR-Blockset regardless of average record length. If you don't specify L5, sort/merge will try to use VLR-Blockset.

When used, the new VLR-Blockset technique will generally show processing time improvement over Vale.

CONDITIONS FOR USE OF BLOCKSET SORTING TECHNIQUES

The sort/merge program has two high-performance disk sorting techniques, FLR-Blockset and VLR-Blockset, for fixed- and variable-length records, respectively. The program will first attempt to use one of these techniques, providing the following conditions are fulfilled. If they are not, then one of the other standard disk sorting techniques, Peerage or Vale, may be used where possible (Peerage or Vale for fixed-length records; Vale for variable-length records).

The first list below includes conditions common to both techniques. The second list includes conditions relevant to FLR-Blockset only, and the third, to VLR-Blockset only.

Conditions Common To Both Blockset Techniques

- More than about 64K bytes of main storage plus additional storage for buffers are available for sort and other possible modules in the region/partition. The larger the input/output block sizes are, the larger main storage must be.
- No program exits other than E15 and/or E35 (without overlay structures) provided they are pre-linkedited.
- If a SORTCNTL DD statement is used, no control statements other than OPTION should be included.
- Tape work data set is not specified.
- Under MVS, up to 26 dynamically allocated sort work data sets may be used, depending on the complexity of the control field and use of SMF.
- Input or output is not a VSAM or an ASCII data set, or track overflow record format (RECFM=FT).
- Input is not a direct-access data set with key sequenced organization (BDAM).
- Input or output must not be a spool or a dummy data set.
- Output cannot be padded or truncated records, or an old data set residing on tape.
- Multivolume disk data output is not requested.
- Checkpoint is not specified.
- Control fields that do not exceed 248 bytes.
- Control fields that do not cause the intermediate record to expand by more than 30% of the total record length. Factors that might expand the record are overlapping fields, decimal fields, fields that require translation, or specification of EQUALS.
- All supported control field formats except those with leading, trailing, overpunched, or separate signs, or ASCII format control fields.
- Skipping of input records is not requested.

FLR-Blockset Conditions

- SORTIN record length plus 13 bytes and any additional bytes caused by control field expansion must not exceed the smallest SORTWK track capacity or 32K bytes, whichever is smaller.
- Record length is not to be changed by program exit E15 and/or E35.
- SORTWK data sets must be allocated in cylinders (MVS only).

VLR-Blockset Conditions

VLR-Blockset minimum storage requirements are defined by the following computations (whichever results in the larger value should be used, but in no case should less than 69K bytes be used):

- In computing the amount of storage necessary to execute VLR-Blockset, use whichever of the following computations resulting in the largest value:
 1. 48K bytes of main storage plus the largest of three times:
 - a. the maximum input block size, or
 - b. the maximum output block size, or
 - c. 2000 bytes.
 2. 48K of main storage plus four times the size of the maximum record length, plus the largest of the following:
 - a. the maximum input block size, or
 - b. the maximum output block size, or
 - c. 2000 bytes.
- Maximum record length does not exceed the track length for the SORTIN or SORTOUT disk data set, or 32,000 bytes, whichever is smaller.
- Input or output is not spanned, variable-length records.
- Input or output is not Format D records (variable-length ASCII tape records).
- Work data sets are specified (a sort in main storage is not supported).
- The sort/merge program is not dynamically invoked by IMS/VS for variable-length record sorting applications.
- The control field does not overlap the record descriptor word (RDW).
- If the ratio of region size to the number of input records is large, and if the L5 operand specified on the RECORD control statement is greater than 350 bytes, sort/merge may, in some cases, choose to use the Vale technique. If L5 is not specified, sort/merge will execute VLR-Blockset if all other conditions are met.

Program Structure

As shown in Figure 1, the program operates in four major phases. The first part of Phase 0 reads and interprets program control statements, and selects the technique to be used.

| For a merge there is only one technique.

| TAPE SORT TECHNIQUES

| If tape is specified for work areas one of the conventional tape sorts (BALN, POLY, or OSCL) is used. The choice of technique depends solely on the numbers of work and input tapes specified.

| DISK SORT TECHNIQUES

| For a disk sort the program selects one of three standard techniques: BLOCKSET, PEERAGE, or VALE.

| The program's most efficient technique, BLOCKSET will be used for most sorting applications fulfilling the following conditions:

- | • Fixed-length records up to the length of the smallest SORTWK disk track size
- | • More than about 60K bytes of main storage available for sorting and possible modules in the region/partition
- | • No program exits other than E15 and/or E35, provided they are prelink-edited
- | • Input or output is not:
 - | - VSAM data set
 - | - ASCII data set
 - | - Data set with track overflow record format (RECFM=FT)
 - | - Direct access keyed sequenced data set
 - | - Residing on a device type not supported as a sort work area
 - | - Spool data set or dummy data set

If these conditions are not met, the program will attempt to use Peerage or Vale. Peerage is normally used if the following criteria are met:

- Fixed-length records
- Record length no greater than track length
- No exits to be activated other than E15, E18, E35, E39, or E61
- Control word not too long (see note)

Note: No figure can be given for how long the control word can be if the Peerage technique is to be used; it depends on many variables, such as device type for work storage and amount of main storage available for buffers. However, the length limit is unlikely to be reached before 256 bytes, and will usually be considerably higher.

If any one of the conditions mentioned above is not satisfied, the program will attempt to use Vale.

The user should not normally need to be aware that these different techniques exist. In the OS/VS Sort/Merge Programmer's Guide, they are collectively referred to as the "standard disk technique." However, it is possible to specify, when the program is installed or in the OPTION or DEBUG statement on execution, that a Blockset technique should not be used.

An informational message (ICE092I or ICE093I) states which of the standard disk techniques has been used.

The conventional disk sorts supplied with the program (BALN and CRCX) can be forced by a parameter of the DEBUG statement. Care should then be taken that the SORTWK requirements for the forced technique have been met. For information on these requirements, refer to the OS/VS Sort/Merge Programmer's Guide.

*If all records fit in main storage or just 1 string of data written on SORTWKs, the key handling is bypassed.

Figure 1. Phases of the Program

Operational Considerations

The program may be initiated by an EXEC statement or invoked from a processing program, as shown in Figure 2.

Figure 2. Initiation of the Program

For an EXEC sort or merge, control information is supplied via the following control statements in SYSIN: SORT, MERGE, OPTION, RECORD, MODS, ALTSEQ, DEBUG, and END.

For a sort or merge invoked from an assembler-language program, control information is supplied in a parameter list and SORTCNTL. For COBOL and PL/I, additional information may be passed via the SORTCNTL data set.

Figure 3 gives an example of the use of the ATTACH macro instruction.

User routines for use at program exits may be located in partitioned data sets defined by the user in the MODS statement, or may be in SYSIN, in which case they are copied into the SORTMODS data set. The user defines link-editing requirements: none, separate, or together with other routines for the same phase.

Figure 3. Initiation Via the ATTACH Macro

Physical Characteristics

When a standard disk technique is used, the program is reenterable.

MAIN STORAGE

The program needs a minimum of 48K bytes of main storage. If performance is a consideration you should allocate at least 72K bytes, and preferably between 128K bytes and 512K bytes.

The program will make use of all available main storage in the partition or region if SIZE(MAX) is in effect; this can be specified either at installation or at execution. The MAXLIM parameter should have been specified at installation time: this sets an upper limit to the amount of space which the program can use. If it has not been specified, and SIZE(MAX) is used in a very large virtual partition or region, performance will usually deteriorate and deactivation may result.

LIBRARIES

There are two link libraries designated for your sort/merge program--one containing the reenterable routines, and the other containing non-reenterable initiating routines. In addition, a sort library containing all other sort/merge routines as well as space in the system SVC library is designated when you are using any sort application with tape work areas or any merge application, or if any of the nonstandard disk techniques are forced. If sort/merge cataloged procedures are used, space in a procedure library is also designated.

System Libraries

The system libraries usually used are shown in Figure 4. In addition, Figure 5 shows how the data sets are used during execution of sort/merge.

<u>System Libraries</u>	<u>VS1 (also MVT, MFT)</u>	<u>SVS, MVS</u>
Link library (reenterable modules)	SYS1.LINKLIB	SYS1.LPALIB
Link library (non- reenterable modules)	SYS1.LINKLIB	SYS1.LINKLIB
Sort library	SYS1.SORTLIB	SYS1.SORTLIB
SVC library	SYS1.SVCLIB	SYS1.LPALIB
Procedure library	SYS1.PROCLIB	SYS1.PROCLIB

Figure 4. System Libraries

If SYS1.PROCLIB is used for procedures, any earlier SORT or SORTD procedures (SM-023 or 5734-SM1) should be scratched.

Private Libraries

If you have more than one operating system and use private libraries, only one set of modules is needed (except for the SVC routine, which is dependent on the system under which you are running; it must always be in a system library).

DATA SETS

Temporary data sets are used at execution time. These are illustrated in Figure 5.

Figure 4. The Installation Procedure

Figure 5. Data Sets Used Only During Execution

Section 2: Method of Operation

This section gives a functional description of the sort/merge program, with cross references to other parts of the manual. It also provides an entry into the microfiche by showing which modules perform which function. It does not, however, describe in detail the various techniques used by the program.

How the Section Is Organized

The section contains information in four forms:

1. A hierarchical overview of the functions of the program, Figure 6, which also serves as a table of contents to the diagrams.
2. The Method of Operation (MO) diagrams, each describing a function of the program in the form input-process-output.
3. Extended descriptions accompanying each lowest-level diagram.
4. Module tables accompanying each lowest-level diagram for conventional techniques, showing which modules perform which function. For peerage and vale modules this information is included in the extended descriptions.

How to Use the MO Diagrams

To find the diagram you need, refer to the overview (Figure 6).

The diagrams are arranged with the processes (functions) listed and numbered in the central block. Start reading in that block, and refer to the left-hand column to find input to each function, and the right-hand column for output. The extended descriptions give more detailed information.

REFERENCES TO DATA AREAS

| The program makes extensive use of a large data area. For Blockset, the area is called COMMON. See Section 5 for the area layout. For Peerage and Vale applications the area is called COMMA, and its layout can be found in Section 5. For other applications the information in COMMA is moved in Phase 0 to a 'control phase information area', the CPI, and thence to a 'phase-to-phase information area', the PPI, the DSECT for which resides in module ICERCA.

| Virtually all parts of the program use COMMON, COMMA, or the PPI. This is not therefore normally shown in the MO diagrams; exceptions are made when for example updates to COMMON, COMMA, or the PPI, form the major output from a function.

The data areas themselves are described in detail in Section 5 of this publication. To find which specific fields are referenced by a particular CSECT, see the cross-reference list in the relevant microfiche. To find which modules reference a specific field, see the cross-reference tables in Section 6.

SYMBOLS USED

Processing sequence

Entry into a diagram is shown from the previous diagram on the same level; if none exists, the next higher level is shown. Exit from a diagram is shown in the same way.

Data movement
For example:

Process X moves record A from area 1 to area 2.

Process 1 moves records from an input buffer to an output buffer. Process 2 moves them from the output buffer to a SORTWK data set.

Process A moves records from an output buffer to the SORTOUT data set. It also passes control to any user routine present at exit E35, which may also move records to SORTOUT.

- Pointer - the field from which the arrow originates contains the address of the field or area to which the arrow points. This symbol is also used in the extended descriptions to the diagrams, as follows: '...Exit Name Table (†PPIAPGC means that a pointer to the Exit Name Table can be found in PPIAPGC.
- - - -→ Data Reference - the process block from which the arrow originates accesses the information in the area to which the arrow points, without modifying it.
-  Diagram Reference - the functions in the process block are described in greater detail in diagram N.

How to Use the Module Tables

Function

Relates to a function in the process column of the relevant diagram. To find which module carries out the function, follow across to the next column.

Conditions

Work from left to right choosing the conditions which apply to your application.

Mod

Gives the last three or four letters of the name of the module which carries out the function. A directory of modules is given in Section 4.

When a running module carries out a function it alone is referenced, though the corresponding assignment module is of course also necessary to the function. When an assignment module actually carries out the function, it alone is referenced. See Section 4 for more information on assignment and running modules.

ABBREVIATIONS USED IN MODULE TABLES

Fix	fixed-length records
Var	variable-length records
Exit	one or more program exits activated
No E	no program exits activated
256+	records of 256 or more bytes
<256	records of less than 256 bytes
Mult	a multiple compare routine used

Figure 6. Table of Contents for Method of Operation Diagrams
Hierarchical Overview of Program Functions

1

Sort/Merge

Extended Description for Diagram 1

1. Analyze control information

Determine whether the application is a Blockset, Peerage, or Vale technique sort, or a conventional technique Sort or Merge.

Initialize for the appropriate application.

2. Blockset sort

Sort input into ordered strings, attempting to limit the key range of cylinders.

Create optimal virtual block sets from physical blocks on work file cylinders.

Merge virtual blocks to produce final output.

3. Peerage or Vale sort

Sort input into ordered strings, using the replacement selection technique.

For Peerage, partition the work files. The partitioning technique is shown in MO diagram P3.2.

Reduce the number of strings.

Merge the strings to produce final output.

4. Conventional Sort

Sort input into ordered strings, using the replacement selection technique.

Reduce the number of strings.

Merge the strings to produce final output.

Merge

Merge the input files to produce final output.

Definition

Extended Description for Diagram D2

1. Process program options (default and specified), JCL information, and program control statements.

Optimize control field specifications.

Check Blockset technique criteria (listed in Section 1 under 'Program Organization').

2. Initialize for Blockset:

Generate code to handle control fields.

Make the program reenterable.

Set up control block areas.

Optimize.

3. Process program options (default and specified), JCL information, and program control statements.

Optimize control field specifications.

Check Peerage technique criteria (listed in Section 1 under 'Program Organization') to determine whether this is a Peerage technique sort; if the criteria are not met, check Vale criteria (also listed in Section 1).

4. Initialize for Peerage or Vale Sort:

Generate code to handle control fields.

Make the program reenterable.

Set up control block areas.

Optimize.

5. Initialize for conventional Sort or Merge:

Build CPI.

Prepare user routines.

Set up program control areas.

Optimize.

D3.1

Analyze and Initialize for Peerage or Vale

Extended Description for Diagram D3.1

1. a. Check generated defaults (stored in Module ICEAM1, described in Section 5).

Scan PARM field parameters from EXEC statement, or (for an invoked sort) the parameter list, pointed to by register 1.

Check that no invalid options selected.

Make appropriate entries in the PPI (see the 'Index to PPI Fields' in Section 5).

b. Check that necessary DD statements are present, and are not duplicated.

Open SORTIN, SYSOUT, and SYSIN or SORTCNTL data sets, and check for valid DCB parameters.

c. Read program control statements, from SYSIN, from SORTCNTL, or from addresses given in the parameter list. Check the statements for correctness and completeness.
2. Generate in main storage a routine for transposing records before sorting them, and for restoring them to their original format after sorting them.

Module
DEF
DEF
DEF
DED
DEC
DEG

3. Move code which is not reenterable to a reserved area:
 - tree handling routines
 - special code
4. Create a control block area for each SORTWK data set. The area holds IOB, DCB, ECB, link fields, and other information.
5. Determine:
 - no. and type of input buffers
 - internal blocksize
 - index size
 - maximum M for phases 2 and 3

Optimize the use of the intermediate storage data sets.

Optimize the mix of SORTIN/SORTOUT buffers and SORTWK buffers, given the way in which the files are allocated, the data transfer rate of the devices, etc.
6. Allocate the number of specified (or defaulted) work areas with the space calculated or using the system's default value. Reallocate VIO data sets with a DSNAME specified, if required.

Module
DEG
DEG
DEV
DEV
DEG

D3.2

Initialization for Conventional Techniques

Extended Description for Diagram D3.2

1. Move information from the communications area to the CPI. Release the communications area. If SIZE (MAX) is in operation, calculate how much virtual storage is available for sorting purposes, and note the amount in the CPI. The CPI is described in Section 5.
2. If user routines are present:
 - a. Copy any routines in SYSIN to SORTMODS.
 - b. If necessary, prepare linkage editor control statements, and put them in SYSLIN.
 - c. If necessary, create a parameter list for the linkage editor.
 - d. Build an exit name table for exits that do not require further linkage editing.
3.
 - a. Transfer the information in the CPI to the PPI. The PPI is described in Section 5.
 - b. Get the storage necessary for the

'permanently generated core' area, to contain the exit name table, the format track table, and the control field handling routine.

- c. Generate the appropriate control field handling routine.

4. For a Sort

- a. Choose the sequence distribution technique to be used.
- b. Calculate bin size.
- c. Calculate variables:
 - B (sort blocking) and G (RSA capacity)
 - maximum M (defined in Section 3 under 'Phase 2')
 - the number of input and output buffers to be used.

For a Merge

- d. Determine the number of input and output buffers to be used.

| Module Table for Diagram D3.2

B2

Blockset Sort

Extended Description for Diagram B2

1. Read input via input buffers into the RSA (Record Storage Area).

| FLR: If end of SORTIN is reached when few or no blocks have been written to SORTWK, bypass the key handling phase. Otherwise, write records to SORTWK to make room for new records to be read into the RSA. Index the blocks written to SORTWK.

| VLR: Write records to SORTWK to make room for new records to be read into the RSA. Collect record length data to use in computing bin size. Index the blocks written to SORTWK. At end of SORTIN, write remaining records to SORTWK and all index records.
2. VLR Generation Phase: Compute bin size and generate code used by output phase to restore records.
- | 3. Sort the indexes created by the SORT phase, and create optimal virtual block sets (physical blocks on same cylinder) for the merge phase.
- | 4. Merge virtual block sets to create the output data.
- | 5. Terminate:

Print information messages.
Close files used.
Free storage used.

B3.1

Initialize Sort

Extended Description for Diagram B3.1

1. Get input records and store, partially sorted, in the Record Storage Area (RSA).
2. a. From partially sorted RSA records select an output block continuing output string, or if no records for current output string begin a new one.
- b. Select a cylinder on SORTWK data sets such that the keys in the

Module
IPUM IPVM
IPUM IPVM
IPUB IPVB

- block to be written are close to keys already written on cylinder.
- c. Write selected records to SORTWK, freeing RSA space for more input records.
 - d. Make block indexes
 3. FLR: If no SORTWK space or one string of data written to SORTWK, skip the key handling phase and go to Merge phase.
- VLR: At input end of file, write remaining records and indexes to SORTWK. Call ICEGENV to initialize code for the OUTPUT phase.

Module
IPUB IPVB
IPUB IPUT
IPVT

B3.2

Key Handling Phase (Prepare Block Sets)

Extended Description for Diagram B3.2

1. Sort the indexes by recursive application of the writeback merge algorithm of the merge phase.

2. Determine virtual block set size, optimize for next phase:

FLR: If the number of strings created by sort is small enough to allow merging without write-back, largest possible block set

Module
KPUS KPVs
KPUT KPVt
KPUV

size is selected.

Otherwise a smaller block set size is selected.

3. Create virtual block indexes:
Process indexes of physical data blocks in key order, and group those on same cylinder with key values sufficiently close together to form virtual block sets.

Module
KPUV
KPUV KPVV

B3.3

Merge

Extended Description for Diagram B3.3

31

	Module		Module
1. Obtain (next) input virtual block index. If necessary read indexes from SORTWK, and/or build new virtual block indexes from writeback physical block indexes. If enough space in RSA for a buffer full of input, continue. Otherwise skip point 3.	OPUT OPVT	If necessary spill indexes to SORTWK index blocks.	
2. Read data blocks. Obtain disk addresses of virtual block set and read those in optimal order into input buffers.	OPUT OPVT	5. Transfer records to output. If RSA and input buffers empty, finish processing. Otherwise return to point 3.	OPUA OPVA
3. Unload input buffers into RSA. Return to point 1. If enough space can be created by moving RSA records to output, skip to point 5.	OPUA OPVA	6. Build and write SMF record if requested (VS1, MVS only).	EXIO OXOV
4. Select records from input buffers and RSA to form part of a writeback string, and write the string to SORTWK in the same way as during phase 1 (sort): Select suitable writeback cylinder, and create indexes for writeback blocks.	OPUT OPVT		

P2

Peerage and Vale Sort

Extended Description for Diagram P2

1. Read input via input buffers into the
RSA (Record Storage Area).

If end of SORTIN is reached before
the RSA is full, SORTOUT can be
written immediately. The tree is
used to select records for output.

Otherwise records are written out to
SORTWK to make room for new records
to be read into the RSA. For Peerage
the blocks written to SORTWK are
indexed.

Peerage

2. Sort the indexes, as described in MO
diagram P4.21.

If the number of logical strings is
<maximum M for phase 3, control is
passed to the final merge (shown in
MO diagram P3). M (merge order) is
explained in Section 3 under 'Phase
1'.

If there are more strings, an
intermediate merge pass is needed.

Partition the blocks on SORTWK, and
arrange the indexes to reflect the
partitioning, as described in MO
diagrams P4.22 and P4.23.

3. Merge all partitions except partition
0, creating new strings on SORTWK.

Return control to point 2.

4. All strings are now in partition 0.

Merge partition 0 to produce the
output data set.

Vale

2. (Not used.)

3. Merge as many strings as possible (M
for phase 2). Repeat until the
number of strings is $\leq$ phase 3 merge
order.

4. Merge the remaining strings to
produce the output data set.

P3.1

Sort

Extended Description for Diagram P3.1

1. Initialize buffers, RSA and tree, and SORTIN.

Move records into the RSA and update the tree for each record.

Continue until the RSA is full (or end of SORTIN is reached) .

2. If end of SORTIN is reached before the RSA is filled, write the output

file.

3. Otherwise, initialize SORTWK data sets.

Create strings of records (and, for Peerage, indexes) for each output block.

4. Write the strings (and indexes) to SORTWK.

P4.11

Read Input

Extended Description for Diagram P4.11

1. Allocate and initialize buffers for SORTWK data sets. Chain the buffer areas together. Allocate and initialize buffers used for SORTIN. (The same buffer area is used for SORTOUT if written in this phase.)
 2. Allocate all remaining main storage to the RSA and tree. Chain bins in the RSA.
 3. Initialize addresses for GET and EOF routines. Load phase 1 routines if specified.
 4. Get a record (from the input buffer or from E15) .
Transpose the record.
Put the record in the next vacant bin in the RSA.
Put the address of the record in the correct place in the tree.
- Repeat until the RSA is full.

Module
CRE/VRE
CRE/VRE
CRE/VRE
CRE/VRE* DEG*
DEG*

If EOF is reached before the RSA has been filled, the records do not need to be written to a SORTWK file. Instead, the SORTOUT file is written, using the tree to locate successive winner records in the RSA.

*The code is generated outside CRE/VRE's area; the source code is held in ICEDEG.

P4.12

Write Output

Extended Description for Diagram P4.12

1. a. Allocate and initialize buffers for SORTOUT. Initialize address for the appropriate put routine. Load E35 routine (if any).

b. Open SORTOUT if it is not a VSAM data set. Close the SORTIN data set.

2. Use the tree to locate the winner record in the RSA.

3. Restore the record to its original format. Move the record to the output buffer (or pass it to the E35 routine).

4. a. If VSAM, put the record to SORTOUT.

b. If non-VSAM, repeat 2 and 3a until the output buffer is full. Write the buffer contents.

Repeat points 2-4 until the RSA is empty.

*The code which carries out these functions is generated outside ICECRO/VRO's area, and resides in ICEDEG.

Module
CRO/VRO
*CRO/VRO
CRO/VRO
CRO/VRO/XCP

P4.13

Create and Distribute Strings

40

Extended Description for Diagram P4.13

1. Set EOF and PUT routine addresses.
2. Move the winner record from the RSA to the output buffer.
Read the next record from the input buffer.
Transpose the record.
Move the record to the bin in the RSA from which the previous winner was moved.
Update the tree.
3. a. Not used for Vale. Create a start index for the logical block, using the control word from the record in the output buffer. Put the index in the output buffer for indexes.
b. Repeat point 2 until the output buffer is full.
c. Write the block to SORTWK.
d. Not used for Vale. Create an end index for the logical block, using the control word from the last record moved to the output buffer. Put the index in the output buffer for indexes.
e. Not used for Vale. Repeat points 2 and 3a-e until the end of a string is reached. At end of string, make up a complete logical block, i.e. fill the last track with dummy physical blocks, so that the next string will begin a new track.

Repeat points 2 and 3 until EOF is reached.

CRE	---
CRE	VRE/VRN
CRE	
CRE	

P3.2

Partitioning

Extended Description for Diagram P3.2

Peerage only (not used for Vale).

1. Read the indexes. Sort them into strings. Index the strings, in the same way as record strings are indexed. Write the indexes to SORTWK. If necessary, merge the higher levels of indexes, until the original indexes are all in one string on SORTWK.
2. In calculating the number of logical strings, physical strings are ignored: only logical blocks are considered. The basis of the algorithm used is that two physical blocks whose contents overlap must necessarily belong to different logical strings. Two blocks whose contents do not overlap, however, can be included in the same string. The indexes can be used to determine whether or not blocks overlap, since they contain the control words of the highest and lowest records contained in the block.
3. Assign each logical block of records to a partition (partitions 0 to n), as described in P4.22. Put the assigned partition number into each index. Partitioning is a form of priming for the following merge step. It enables the merge to read in blocks in the most efficient order, to keep the number of merge passes to a minimum.
4. Sort the indexes (as in point 1), using the partition number as the first control field.

Module
PAR
PAR
PAR

P4.21

Sort Indexes

Extended Description for Diagram P4.21

Peerage only (not used for Vale)

1. Read in the indexes.
2. Sort the indexes, in the same way as records are sorted in phase 1 (see MO diagram P4.12), using an RSA and tree. The first four fields of the index are used as control fields; the partition number in every index is always zero.
3. For each logical block of indexes written out, create a new, second-level index and write it. If the second-level indexes cannot all be contained in one string, create a third level, and so on, until a level is reached at which all indexes can be contained in one string.

If all the sorted first-level indexes are contained in one string, skip points 4 and 5.

4. Carry out successive merges, until only two levels of index remain. Produce a single string from all the first-level indexes.

5. Write the string to SORTWK.

Discard second and higher-level indexes.

Module
PAR
PAR
PAR
PAR
PAR
PAR
PAR
PAR

P4.22

Partition Blocks

Extended Description for Diagram P4.22

Peerage only (not used for Vale)

1. a Read in the string of indexes created in P4.21.
To reduce data handling, the indexes are 'mapped': an 8-byte map entry is created for each pair of indexes, using a hash table.

b Sort the map entries into partitions, in such a way as to maximize the number of logical blocks contained in each successive partition.
Partition 0 contains M-1 strings, where M is maximum M for phase 3. Each of the other partitions contains M strings, where M is maximum M for phase 2. The last partition contains however many strings remain.
2. Using the hash table, transfer the assigned partition number from each map entry to the corresponding pair of indexes.

Module
PAR
PAR
PAR
PAR

P4.23

Sort Indexes

Extended Description for Diagram P4.23

Peerage only (not used by Vale) .

The functions are identical to those performed in p4.21, and are carried out by the same segments.

The index sorting carried out here differs from that described in p4.21 in two respects:

- Indexes entering the routine have been updated to contain the correct partition number.
- Entry is from the partitioning routine, and exit is to a merge routine (intermediate or final). In p4.21, entry is from the sort or intermediate merge routine, and exit is to the partitioning routine.

P3.3

Intermediate Merge (Peelage)

.....

It makes one pass for each partition except partition 0, producing one string from each, and then returns control to the partitioning routine. The partitioning routine continues to call the intermediate merge until the strings can all be contained in partition 0, when it hands control to phase 3 for the final merge.

1. a. Allocate and initialize for SORTWK data sets.
- b. Allocate all remaining main storage to RSA. Chain bins together.
2. a. Read in a block of indexes.
- b. Queue the indexes. Each time an index is removed from the queue, bring in another and merge it into the queue.

Module
RED
RED
RED
RED

3. Read a logical block of records from the address given in the first index in the queue. Merge the records into the RSA. Remove the index from the queue. Repeat until the RSA is full.

- 4,5 Read a block of records from SORTWK to an input buffer.
If necessary, read a block back from the RSA to make room for the incoming block (the criterion for writeback is described in MO diagram P4.31).
Otherwise write a block out from the RSA, and create indexes for it.
Merge the incoming block into the RSA.
Continue until the entire partition has been merged and indexed into one string on SORTWK.

Carry out points 3-5 for each partition except Partition 0.

P4.31

Merge

52

Extended Description for Diagram P4.31

1. Read into the input buffer the logical block of records pointed to by the first index in the index queue.
2. Find out whether enough records can be written out of the RSA to make room for the incoming block.
The space which can be made available is equal to the number of empty bins, plus the number of records (in the RSA and in the incoming block) which 'win' over the first record in the next block that will be read in (pointed to by the next index in the queue).
If this space is smaller than the number of records in the incoming block, writeback is needed.
3. Merge the incoming block into the RSA, each record forcing out one to a buffer.
4. Create an index for the new block and move the block to SORTWK.

If writeback is required, add the index to the index queue; otherwise, write out the index to SORTWK.
5. When there is no more input in this partition, flush out the records remaining in the RSA. The partition is now in one string on SORTWK.

Module
RED
RED
RED
RED
RED
RED

P5.31

Writeback

Extended Description for Diagram P5.31

1. Move the first record from the input buffer into the first vacant bin in the RSA, and chain into its correct position.
2. Move a record from the losing half of the RSA out to a buffer.
3. When a logical block is complete, move it to SORTWK.
4. Create an index for the new logical block.
5. Merge the new index into the index queue (from which blocks of records will be selected for reading in to the current merge pass).

Module

*** = RED in phase 2, LIM/LIV in phase 3.

P5.32

Write

Extended Description for Diagram P5.32

The difference between this function and P5.31 (writeback) is in the handling of the indexes: here, they are written out to the area passed to the partitioning routine; in writeback, they are added to the index queue, so that the block to which they refer will be read in again in the current merge pass.

1. Move the first record in the input buffer into the first vacant bin in the RSA. Chain it into its correct position.
2. Move the winner record from the RSA to the output buffer.
3. When a logical block is complete, move it to SORTWK.
4. Create indexes for the new logical block.
5. Move the new indexes to the index output buffer; when the buffer is full, write it to SORTWK.

Module
RED
RED
RED
RED
RED

P3.4

Final Merge (Peorage)

Extended Description for Diagram P3.4

The differences between the final merge and the intermediate merge (P3.3) are that: input consists of only one partition, partition 0; no new indexes are created; and output is to SORTOUT (or equivalent), not to SORTWK.

1. a. Allocate and initialize for SORTOUT and SORTWK data sets. Open the SORTOUT data set if it is not VSAM.
- b. Allocate all remaining main storage to the RSA. Chain bins together.
2. a. Read in a block of indexes.
- b. Queue the indexes. Each time an index is removed from the queue, bring in another and merge it into the queue.
3. Read a logical block of records from the address given in the first index in the queue. Merge the records into the RSA. Remove the index from the queue.
Repeat until the RSA is full.

Module
LIM/LIV
LIM/LIV
LIM/LIV
LIM/LIV

- 4,5 Read a block of records from SORTWK to an input buffer.
If necessary, read a block back from the RSA to make room for the incoming block (the criterion for writeback is described in MO diagram P4.31). Otherwise write a block out from the RSA, taking E35 after each record is moved out.
Merge the incoming block into the RSA. Continue until the entire partition has been merged into one string on SORTOUT.
6. Write SMF record type 16 to system SMF data set, if requested.

Extended Description for Diagram P4.41

61

- | 1. Read into the input buffer the logical block of records pointed to by the first index in the index queue.
- | 2. Find out whether enough records can be written out of the RSA to make room for the incoming block.
The space which can be made available is equal to the number of empty bins, plus the number of records (in the RSA and in the incoming block) that 'win' over the first record in the next block which will be read in (pointed to by the next index in the queue).
If this space is smaller than the number of records in the incoming block, writeback is needed.
- | 3. Merge the incoming block into the RSA, each record forcing out one to a buffer. Take exit E35.
- | 4. Move the block to SORTWK.
If writeback is required, Create an index for the new block, and add the index to the index queue.
- | 5. When there is no more input, flush out the records remaining in the RSA.

P3.5

Reduce No. of Strings (Vale)

Extended Description for Diagram P3.5

| These functions are carried out by module
| VED; if exit E25 has been specified an
| additional module, VEE, is used to handle
| the interface with the E25 routine.

1. a. Allocate buffers: for input, phase
2 merge order plus one; for output,
two.

b. Initialize the phase work area.

c. Load and call E21 and load E25, if
specified.
2. At the beginning of a merge pass:
 - a. Fill the input buffers.
 - b. Make a simple tree, with one
pointer to the first record in each
buffer, and the pointers
(physically) in the desired output
order.

Subsequently:

- c. Keep the pointers updated to point
to the current record in each
buffer.
- d. Keep the tree order so that the
pointers are in the desired output
order.
- e. Replenish the input buffers when

necessary, using the extra input
buffer for 'smart lookahead'.

3. a. If E25 is not activated:

| Move the record pointed to by the
| first pointer in the tree from its
| input buffer to the output buffer.

- b. If E25 is activated:

| Move the record pointed to by the
| first pointer in the tree from its
| input buffer to the E25 work area.
| Each new record moved to the work
| area forces the preceding record
| out to the output buffer.
| Take E25.

4. When the output buffer is full, write
it to a SORTWK data set and chain it
into the correct place in the string.

Repeat 2c-4 until input is exhausted. If
the number of output strings is now less
than or equal to maximum phase 3 M,
continue to point 5. Otherwise, return
to 2a for another merge pass.

5. a. Load and call E27 if specified.

- b. E25 housekeeping.

- c. Free temporarily allocated areas.

P3.6

Final Merge (Vale)

Extended Description for Diagram P3.6

1. a. Allocate buffers: for input, phase 3 M plus one; for output, the number determined in phase 0.
b. Initialize the phase work area.
c. Load and call E31 if specified.
2. At the beginning of the phase:
 - a. Fill the input buffers.
 - b. Make a simple tree, with one pointer to the first record in each buffer, and the pointers (physically) in the desired output order.

Subsequently:

- c. Keep the pointers updated to point to the current record in each input buffer.
- d. Keep the tree ordered so that the pointers are in the desired output order.
- e. Replenish the input buffers when necessary, using the extra input buffer for 'smart lookahead'.

3. If E35 has been specified:
 - a. Move the record pointed to by the first pointer in the tree from its input buffer to a work area, restoring its original format.
 - b. Call E35.
 - c. On return, move the record passed by E35 to an output buffer.

Otherwise, move the record pointed to by the first pointer in the tree from its input buffer to an output buffer, restoring its original format.

4. When the output buffer is full, write it to the SORTOUT data set.

Repeat 2c-4 until input is exhausted.

5. a. Load and call E37 if specified.
b. Delete all exit routines.
c. Free temporarily allocated areas.
| d. Write SMF record, if requested.

Conventional Sort/Merge

Extended Description for Diagram N2

1. Initialize for phase 1. Take E11, E18, E19.
Get records from SORTIN. Take E15, E16, E18.
Create strings, and distribute them on SORTWK. The sorting technique used is the replacement selection technique.
Take E17.
2. Initialize for phase 2. Take E21, E28, E29.
Read strings of records from SORTWK.
Take E28.

Merge the strings into longer strings. Take E61, E25.
Write out the new strings to SORTWK.
Take E29, E27.

3. Initialize for phase 3. Take E31, E38 and E39.
Read strings of records from SORTWK.
Take E32, E38.
Merge strings into output buffer.
Take E61.
Write out single string to SORTOUT.
Take E35, E39, E37.
Perform final housekeeping.

N3.1

Sort (Phase 1)

Extended Description for Diagram N3.1

- 71
1. The selection of modules is made by ICERC6 using information from PPISW1 combined with the module table TBLPH1RN (which is defined in ICERC6).
Information about user routines not link edited by the program is taken from the Exit Name Table (. PPIAPGC). ICERC9 a) loads all running modules and user routines, then b) loads, executes and deletes the assignment modules one by one.
 2. Take exit 11. Acquire main storage (through GETMAIN) for the phase work area, buffers, and RSA.
Initialize the tree in the phase work area.
Generate the move routine.
Generate control blocks (DCB, IOB, ECB) and CCWs in the phase work area.
Take exits E18 and E19.
Define the RSA bin structure, and enter the relevant information in the PPI.
Open the SORTIN and SORTWK data sets.
Records from SORTIN are skipped if the SKIPREC option is present.
Code in the running modules is initialized by the respective assignment modules.

If the CRCX or OSCL technique is being used some further functions are performed here which otherwise belong to

phase 2; see MO diagram N3.2 for details.

3. Read SORTIN, using QSAM or VSAM.
Locate mode is normally used, but move mode is used for spanned records. Each deblocked variable-length record has its length checked. VSAM variable-length records are supplied with a record descriptor word (4 bytes at the front of the record).
Take exit E15 (record may be altered or deleted or a new record inserted).
If calculated capacity is exceeded, take exit E16.
4. Fill the RSA, updating the tree for each record.
Create strings by moving records from the RSA to a buffer, using the tree to select each record to be moved.
5. Write output, using the EXCP macro instruction.
The sequence in which strings are written to the various SORTWK data sets is determined by the sequence distribution technique used.
6. If exact file size was specified, check the record counts.
Take exit E17.
Close SORTWK data sets.
Free main storage and delete modules.

N4.11

Create Strings

Extended Description for Diagram N4.11

Module Table for Diagram N4.11

1. a. Move a record from the input buffer to the RSA.
 | b. Update the tree.
2. a. Move the winner from the RSA to the output buffer.
 b. Move in the next record from the input buffer.
 c. Update the tree.
 Repeat until there are no more input records; unless the OSCL or CRCX technique is being used, in which case repeat until M-1 strings have been moved to the output buffer.
3. Move remaining records from the RSA to the output buffer.

Function	Conditions			Mod
1a Move	Fix	<256, no E		-
		Other		ABS
1b Update tree	Var			RBF
	Fix	Mult.	POLY	ROE
			Other	ROA

	Var		CRCX,OSCL	RBA
			Other	RBE

¹No special move routine needed--the deblock routine used.

²This module generates a move routine which is kept in main storage (pointed to by PPIBDSVA+4); if the EQUALS option is in operation, an additional routine is also generated (+PPIMOVEQ).

N4.12

Distribute Strings

Extended Description for Diagram N4.12

CRCX disk

One string is written to each of N-1 areas. If a physical area is too small to contain the whole string one or more tracks are borrowed from another physical area. These together make up the logical area. This can be done because each block within the string contains the disk address of the following block; the last block in a string contains its own address. Starting addresses of strings (↑ KTABLEL) and free track list (↑ KFRTRKLT) are kept in the phase work area.

BALN disk

Strings are written to N-1 areas in order of size, starting with the smallest. Eight strings are written to each area at a time, completely filling one directory block. If a complete string does not fit into the remainder of an area it is divided into substrings, the first completely filling the area.

The directory contains the starting address of the string, and the remaining blocks follow consecutively. The last block of the string contains a special EOS indicator.

BALN tape

Strings are written to N/2 tapes, one at a time. If a string does not fit on a tape it is divided into substrings.

OSCL tape

One string is written to each of N-1 tapes.

POLY tape

Strings are written to N-1 tapes, one at a time, until the lowest of the next level Fibonacci numbers is reached; then to N-2 tapes until the next number at the same level has been reached, and so on. When a complete level has been reached the next level numbers are calculated and the process is restarted. When all strings have been distributed dummy strings are added if necessary to make up Fibonacci numbers. The numbers of real and dummy strings are kept in PPITPTBL.

Module Table for Diagram N4.12

Function	Conditions	Mod
1a Sequence Distribution algorithm	CRCX	8ON
	OSCL	RON
	BALN (disk)	ROK
	BALN (tape)	ROI
	POLY	ROJ
1b Write	CRCX	8PA
	BALN (disk)	RPE
	Other	RPA

N3.2

Intermediate Merge (Phase 2)

Extended Description for Diagram N3.2

79

1. The selection of modules is made by ICERC7 using information from PPISW1 and from the module table TBLPH2RN*. Exit information is taken from the Exit Name Table (+PPIAPGC). ICERC9 a) loads all running modules and user routines, then b) loads, executes and deletes the assignment modules sequentially.
2. Take exit E21*.
Acquire main storage (through GETMAIN) for the phase work area and for buffers.
Generate the record move routine.
Build the input buffer table and network table in the phase work area*.
Generate control blocks (DCB, IOB, ECB) and CCWs in the phase work area.
Take exits E28 and E29*.
Open the SORTWK data sets.
Code in the running modules is initialized by the respective assignment modules.

Points 3, 4 and 5 are repeated until no input strings are left:

3. Read one string from each input tape--unless BALN (disk) is being used, in which case read M (or remaining, if less) strings at a time from one area (the largest of those with strings from the previous phase). For reading, the EXCP macro instruction is used.
4. Store the address of one record from each string (or its extracted control fields) in a network table (+PPINETAR).
Take exit E61.

Find the next record to be moved to the output buffer, using binary search.
Put the address of the next record in the 'winner's' string in the network table.
Take exit E25.

5. For writing, the EXCP macro instruction is used.
CRCX: The string is written to the area not used as input.
OSCL: The string is written to the next tape.
BALN (disk): The string is written to the output area left empty by the previous phase or emptied in this pass.
BALN (tape): The string is written to the next tape.
POLY: The string is written to the only available tape.

If the CRCX or OSCL technique is being used, the program returns from here to Phase 1 (see diagram N3.1), unless a) there is no more input, or b) the current level of strings now numbers M, in which case it repeats points 3-5.

6. Take exit E27.
Check the record counts.
Close the SORTWK data sets.
ICERCT free main storage and deletes modules.

Unless the CRCX or OSCL technique is being used, the entire phase is re-executed until only one more merge pass is needed.

*When the CRCX or OSCL technique is used, these steps are executed in phase 1; see MO diagram N3.1

Module Table for diagram N3.2

N3.3

Final Merge (Phase 3), or Merge Only

Sort: from N3.2
or N3.1
Merge: from D3.3

Extended Description for Diagram N3.3

1. The selection of modules is made by ICERC8 using information from PPI5W1 combined with the module table TBLPH3RN.
Exit information is taken from the Exit Name Table (.PPIAPGC).
ICERC9 first loads the running modules and user routines, then loads, executes and deletes the assignment modules sequentially.
2. Take exit E31.
Acquire main storage (through GETMAIN) for the phase work area and buffers.
Generate the move routine in the phase work area.
Build control blocks (DCB, IOB, ECB) and CCWs in the phase work area.
Take exits E38 and E39.
Open SORTOUT and the input data sets.
Code in the running modules is initialized by the respective assignment modules.
3. For a sort, the strings are read from the SORTWK data sets.
For a merge, the input strings are the SORTINnn data sets, or are supplied through E32.
4. Take exit E61.
The address of one record from each input string (or of its extracted control fields) is kept in a network table (#PPINETAR). The next record to be moved to the output buffer is determined using binary search.
The address of the next record in the 'winner's' string is put in the network table.
5. Take exit E35. The record may be altered or deleted or a new record inserted. The current record is then written to SORTOUT. The program uses QSAM or VSAM for writing output. Normally locate mode is used, but move mode is used for spanned records.
6. Take exit E37.
Check record counts.
Close data sets, free main storage, and delete modules.

Section 3: Program Organization

Page of LY33-8042-6, As Updated 31 March 1981, By TNL LN20-9345

This section describes the structure of the sort/merge program, and of each of the phases that make up the program. For a sorting application all phases are normally used, as shown in Figure 1 in Section 1. For merging applications, only the first and last phases are used.

The interface between the various load modules is shown.

The phases are described, and a cross reference given to the appropriate MO diagrams in the Method of Operation section (Section 2). Record movement is also described.

Phase structures and storage layouts are shown in figures at the end of this section.

Program Exit Handling

Provisions are contained in Phases 1, 2 and 3 for inclusion of user routines at program exits. The linkage editor includes the user routines in the load module for the appropriate phase; however, when proper specifications are provided on the MODS control statements, link-editing does not occur, and the routines are loaded by the phase loader modules. See Appendix A for the various exits.

Module Interface

The interface of load modules in the program is shown in Figure 7.

While ICERCB is in main storage a patch area of 48 bytes (hex 30) is available. It is located at offset 1132 (hex 46C) from the start of the PPI area. Register 13 points to the PPI. The area is initialized with binary zeros.

When Phase 1 of Blockset (ICEIPUT for FLR, ICEIPVT for VLR) detects an error condition, it hands control to either ICEMESI or ICEMSGV, respectively. Phase 3 hands control to ICEMESO. When error conditions are detected in Phase 1, 2, or 3 of the other techniques, control is handed to the phase interface module (ICEMON for Peerage and Vale techniques, and ICERCV for the other techniques). The phase interface module handles the issuing of the appropriate message.

Figure 7. (1 of 4). Load Module Interface, FLR-Blockset

Figure 7. (3 of 4). Load Module Interface, Peerage and Vale

Figure 7. (4 of 4). Load Module Interface, Conventional Techniques

Phase 0

This phase collects the current system and sort control card information. It then decides which technique to be used and does the internal sort optimization. The functions are described in MO diagram D2. For conventional techniques, an SMF record type 16 is written to the system SMF data set, if requested.

Phase 1

Phase 1 performs the initial ordering of the input records. This is a one-pass phase (that is, each record is processed only once) that arranges the records of the input data set into ordered sequences. The sequences are written on the intermediate storage devices according to a predetermined distribution procedure.

With Blockset and Peelage, but not with Vale, an index entry is created for each work file block. This entry contains the control word of the first record in the block, and the block's disk address.

For Blockset applications this phase is described in MO diagram B3.1; for Peelage and Vale in MO diagram P3.1; for other techniques in MO diagram N3.1.

The input of records is controlled by EXCP, or by the SAM access method, and output is controlled by the sort/merge program--unless the application is a standard disk sort which needs no work storage, in which case EXCP or SAM is used to produce the output data set. The sorting method used to order the records into sequences is a version of the replacement-selection technique.

When the conventional OSCAL tape or CRCX disk techniques are used, control alternates between Phase 1 and Phase 2. With the BALN tape or disk technique, Phase 1 is first completed and then control is handed to either Phase 2 or Phase 3.

Phase 2

BLOCKSET TECHNIQUE

This phase processes the index entries from Phase 1 and assigns each block to a cylinder block set for merging. Two construction algorithms are used: one for a merge which writes only to the output file, and one for a merge which also writes to the work file.

This phase is described in MO diagram B3.2.

OTHER TECHNIQUES

For all other techniques, this phase combines the sequences produced by Phase 1 into a lesser number of longer sequences. It makes as many passes as necessary until the number of record sequences resulting from a given pass is equal to or less than the maximum Phase 3 merge order.

The merge order (M) is the number of sequences merged in any one merge pass. Maximum M for a given application is limited by the number of intermediate storage areas available, by the technique being used, and frequently by the number of buffers which can be accommodated in available main storage.

Phase 2 continues, therefore, until the total number of sequences remaining on all work areas is less than or equal to maximum M for the application in question.

Peerage Technique

This phase is described in MO diagrams P3.2 and P3.3.

The phase is in two parts, carried out by modules ICEPAR and ICERED. ICEPAR receives control after Phase 1 (ICECRE). It partitions the files, i.e. rearranges their indexes so that they will be read in by the merge in the most efficient order. If necessary, ICEPAR then initiates an intermediate merge: it instructs ICEMON to hand control to ICERED, which after merging returns to ICEPAR via ICEMON. This process continues until ICEPAR detects that the program is ready to enter Phase 3.

Vale Technique

This phase is described in MO diagram P3.5.

Each pass can merge up to 64 sequences. Two output buffers are used. The number of input buffers is M (merge order) + 1; the extra one is for 'smart lookahead', which means that when a buffer from a given sequence is emptied its next block should already be in main storage.

Conventional Techniques

This phase is described in MO diagram N3.2.

Each pass is capable of merging up to 16 previously sorted record sequences, or 63 if the balanced disk technique is used.

When the OSCI or CRCX techniques are used, control alternates between Phase 1 and Phase 2.

Phase 3

Phase 3 is a one-pass phase and produces a single ordered record sequence, thus completing the application.

For Peerage this phase is described in MO diagram P3.4; for Vale in P3.6; for Blockset in MO diagram B3.3; and for other techniques in N3.3.

In a sorting application, it follows Phase 2 (or Phase 1 if a Vale, Blockset, or conventional sort, skips Phase 2). In a merging application, it is executed immediately after Phase 0.

For a merging application, record input and output operations are performed by the control program's data management routines. For the final merge of a sorting application, Sort handles the record input operation, and EXCP or SAM is used to handle the record output operation, as in a merging case.

At the end of this phase for Blockset, Peerage, and Vale, an SMF record type 16 is generated and written to the system's SMF data set, if requested as an installation option.

Phase Structures

The Blockset, Peerage, and Vale technique phases consist normally of one load module each.

With other techniques the load modules are either planned overlay structures or dynamic structures. The organization of each phase with planned overlay or dynamic structures, and the modules that comprise them, are presented on the following pages. The modules for each phase are not necessarily placed in contiguous storage locations. In the case of dynamic phase structures, the modules are presented in the order in which they receive control.

Storage Layouts

BLOCKSET, PEERAGE, AND VALE TECHNIQUES

| Storage is allocated as follows:

- | 1. Phase 0 issues a GETMAIN primarily for the communications area, COMMON or COMMA, and the extract/restore code area, which is variable in length.
- | 2. If SORTWK data sets have been defined, a GETMAIN is issued for the necessary I/O area. Storage is also allocated to the Checkpoint/Restart track pool if necessary (though not for Blockset).
- | 3. End of Phase 0 frees whatever part of the first area is not needed by COMMON or COMMA and the extract/restore code area.
4. Phases 1 and 3 begin by getting space for buffers for SORTIN and SORTOUT.
5. Each of the Phases 1-3 gets the remaining required storage by issuing a series of variable GETMAINS until it reaches SIZE or MAXLIM. At the end of the phase it frees this storage again.

OTHER TECHNIQUES

The storage allocation technique used is such that main storage is first allocated for necessary or required areas (proceeding from the largest to the smallest), and then for the optional areas (in priority order). This is accomplished by issuing variable-type requests for main storage. The minimum request is equal to the size of the largest necessary area; and the maximum, equal to the total size of all areas.

If additional main storage is needed, the unused portion of the previous allocation is made available for subsequent allocations. The minimum request becomes equal to the size of the area next-in-line to be allocated; and the maximum, equal to the total size of all unallocated areas. (This process is continued until either all areas are allocated, or the minimum request cannot be satisfied.)

Section 4. Directories

This section lists all module names: first Blockset, then Peerage and Vale, then conventional technique modules. Each list is in alphabetical order. Cross references are given to other parts of the publication.

Blockset Directory

This directory lists Blockset object modules. Their names are in the form ICEmod, where mod is the three or four character identification of the module. Only these last characters are listed. The list also gives a reference to the Method of Operation diagrams (MO diag) provided in Section 2.

Module Name	Used in Phase:	FLR or VLR	MO Diag	Purpose
AM1	0	FLR/VLR		Supply installed defaults
CKUT	3	FLR	B3.3	Sortout check
COBU	3	FLR	B3.3	Exit E35 interface for invoked sort
COBV	1	VLR	B3.1	Exit E15 with no SORTIN interface
CYLN	1,2,3	FLR/VLR		Cylinder selection
DEVT	All	FLR/VLR		Device table
DYNA	0	FLR/VLR	D3.1	Dynamic allocation of SORTWK (MVS only)
EXII	1	FLR	B3.1	Phase 1 exit
EXIK	2	FLR	B3.2	Phase 2 exit
EXIN	0	FLR/VLR	D3.1	Phase 0 exit
EXIO	3	FLR	B3.3	SMF write and final exit from sort
EXIT	3	FLR	B3.3	Final exit point
E15B	1	FLR	B3.1	Exit E15 interface
E35B	3	FLR	B3.3	Exit E35 interface
FAUL	0	FLR	D3.1	Initialization values
FILI	1	FLR	B3.1	Load module filler
FILK	2	FLR	B3.2	Load module filler
FILO	3	FLR	B3.3	Load module filler
FORM	0	FLR	D3.1	Control field format tables
FVLI	1	VLR	B3.1	Input phase load module filler
FVLK	2	VLR	B3.2	Key Phase load module filler
FVLN	0	FLR/VLR	D3.1	Phase 0 load module filler
FVLO	3	VLR	B3.3	Output phase load module filler
GENV	1	VLR	B3.1	Point input code generation
INIB	0	FLR/VLR	D3.1	Control statement handling
INIC	0	FLR/VLR	D3.1	Generate extract/restore code
INID	0	FLR/VLR	D3.1	Initialize move and tree code
INIO	0	FLR/VLR	D3.1	Transfer conditions for other techn.
IPUB	1	FLR	B3.1	Phase 1 I/O handling
IPUM	1	FLR	B3.1	Handle records and indexes
IPUT	1	FLR	B3.1	Initialize for Phase 1
IPVB	1	VLR	B3.1	Input phase I/O handler
IPVM	1	VLR	B3.1	Handles input records and indexes
IPVT	1	VLR	B3.1	Initialize for input phase
FLR = fixed-length record VLR = variable-length record				

Module Name	Used in Phase:	FLR or VLR	MO Diag	Purpose
KPUA	2	FLR	B3.2	Virtual block construction
KPUB	2	FLR	B3.2	Phase 2 I/O handling
KPUS	2	FLR	B3.2	Virtual block construction
KPUT	2	FLR	B3.2	Initialize for Phase 2 or 3
KPUV	2	FLR	B3.2	Virtual block construction
KPVA	2	VLR	B3.2	Virtual block construction
KPVB	2	VLR	B3.2	Key phase I/O handler
KPVS	2	VLR	B3.2	Key phase writeback merge
KPVT	2	VLR	B3.2	Initialize for key and output phases
KPVV	2	VLR	B3.2	Virtual block construction
LIMI	3	FLR	B3.2	Writeback limit
MAN	0	FLR/VLR	D3.1	Handle parameter list and DD statements
MESI	1	FLR		Handle Phase 1 messages
MESS	All	FLR/VLR		Message handling
MESV	1	VLR		Handle input phase messages
MSGI	1	FLR/VLR		Phase 1 messages
MSGK	2	FLR/VLR		Phase 2 messages
MSGN	0	FLR/VLR		Phase 0 messages
MSGO	3	FLR/VLR		Phase 3 messages
OPUA	3	FLR		Phase 3 subroutines
OPUB	3	FLR	B3.3	Phase 3 I/O handling
OPUT	3	FLR	B3.3	Handle records and indexes
OPVA	3	VLR	B3.3	Output phase subroutines
OPVB	3	VLR	B3.3	Output phase I/O handler
OPVT	3	VLR	B3.3	Main output driver
OXIV	3	VLR	B3.3	Output exit and message entry points
OXOV	3	VLR	B3.3	SMF write and final exit from sort
SUBS	1,3	FLR		Suballocate main storage
SUBX	1,3	VLR		Suballocate main storage
XPUT	1,2,3	FLR		Load user exits
15V	1	VLR	B3.1	Exit E15 with SORTIN interface
35VL	3	VLR	B3.3	Exit E35 interface
FLR = fixed-length record VLR = variable-length record				

Peerage and Vale Directory

This directory lists Peerage and Vale load modules. Their names are in the form ICEmod, where mod is the three or four character identification of the module. Only these last characters are listed. The list also gives a reference to the Method of Operation diagrams (MO diag) provided in Section 2.

Module Name	Used in Phase:	MO Diag	Purpose
AM1	0		Supply installed defaults
BUG	All		Handle formatted dumps
CKP	2		Prepare for checkpoint and/or release unused work space
COM	All		Source code for ICECOMMA (formatted dump)
CRE	1	P3.1	Manage Phase 1
CRO	1		Final output in Phase 1
DEC	0	D3.2	
DED	0	D3.2	Manage Phase 0 (part 1)
DEF	0	D3.2	
DEG	0	D3.2, D3.3, P3.1	Manage Phase 0 (part 2)
DEV	0	D3.3	Manage Phase 0 (part 3)
ERR	0,1,3		Handle VSAM I/O errors
FIX	0,1		Page fixing and freeing (SVC)
(SVS/VS1)			
FIXO (OS)	0,1		DEB modification for I/O chaining (SVC)
LIM	3	P3.4	Manage Phase 3
LIV	3	P5.31	Handle VSAM output in Phase 3 (Peerage only)
MAN	0	D3.1	Handle transfer from Blockset
MON	All		Overall program management
OBS	0		Open for SORTIN/SORTOUT EXCP
PAR	2	P3.2	Manage Phase 2 (partitioning)
RED	2	P3.3	Manage Phase 2 (merging)
VED	2	P3.5	Manage Phase 2 (merging, with variable length or very long records)
VEE	2	P3.5	Take E25 if specified
VIM	3	P3.6	Manage Phase 3 (variable length or very long records)
VIP	3		Initialize Phase 3
VRE	1	P3.1	Manage Phase 1 (variable length and very long records)
VRN	1	P3.1	Manage Phase 1 (variable length or very long records)
VRO	1		Final output in Phase 1
XCP	0		Build channel programs for SORTIN and SORTOUT

Directory for Conventional Techniques

The names are listed alphabetically. All CSECTS are included, plus any other labels referenced in other sections of this publication.

EXPLANATION OF COLUMN HEADINGS

CSECT Name

Naming conventions are described in Appendix D.

Each CSECT name consists of six characters, the first three of which are always ICE. For easy reference, the names are listed by their last three characters only. In Phases 1, 2 and 3 those which begin with 'A' or '9' are generally assignment modules, and those which begin with 'R' or '8' are running modules. With a few exceptions, module Axy will carry out assignment for module Rxy, and so on.

Used in Phase:

The phases are:

- 0 (Def) - Definition
- 0 (Opt) - Optimization
- 1 - Sort (only for sorting applications)
- 2 - Intermediate merge (only for sorting applications)
- 3 - Final merge

The first and last phases have some alternative modules for sorting applications and for merge-only applications, which are indicated as follows:

- 3 Sort - Used in Phase 3 of a sorting application
- 3 Merge - Used in the merge phase of a merge-only application
- 3 All - Can be used in this phase for all applications

The words 'sort', 'merge' and 'all' are used with 0 (Def) and 0 (Opt) in the same way.

MO Diagram

Provides a cross reference to the relevant diagram in the Method of Operation section (Section 2).

Purpose

The major purpose of the CSECT is briefly described. Keep in mind the notes on modules beginning with 'A' and '9' (above, under 'CSECT Name').

- Mult - Means a multiple compare routine is used to compare control fields;
- No Mult - Means it is not;
- Extract - Means an extract routine is used to compare control fields.

CSECT Name	Used in Phase:	MO Diag	Purpose
ABA	1		CRCX & OSCL: block var. records
ABB	1		Block fixed-length records with in-line move
ABC	1		Block fixed-length records with link to multiple move
ABE	1		Block var. records with move
ABF	1		Move var. records
ABG	2		Block or deblock fixed-length records with in-line move (no exits)
ABH	2		Block or deblock fixed-length records with link to multiple move (no exits)
ABI	2		Block or deblock var. records (no exits)
ABJ	2		Block or deblock fixed-length records (exits used)
ABK	2		Block or deblock var. records (exits used)
ABL	3 all		Block fixed-length records with in-line move (no exits)
ABM	3 all		Block fixed-length records (exits used)
ABN	3 all		Block var. records (no exits)
ABO	3 all		Block var. records (exits used)
ABP	3 all		Block fixed-length records with link to multiple move
ABQ	3 all		Move generator for fixed-length records
ABR	2	N3.2	Move generator for fixed-length records
ABS	1	N4.11	Move generator for fixed-length records
ABT	2		CRCX & OSCL: block/deblock fixed-length records up to 256 bytes (no exits)
ABU	2		CRCX & OSCL: block/deblock fixed-length records >256 bytes (no exits)
ABV	2		CRCX & OSCL: block/deblock var. records (no exits)
ABW	2		CRCX & OSCL: block/deblock fixed-length records (exits used)
ABX	2		CRCX & OSCL: block/deblock var. records (exits used)
ABY	1		CRCX & OSCL: block fixed-length records up to 256 bytes
ABZ	1		CRCX & OSCL: block fixed-length records >256 bytes
ADB	1		Deblock fixed-length records with in-line move (no exits)
ADC	1		Deblock fixed-length records with link to multiple move (no exits)
ADD	1		Deblock fixed-length records (exits used)
ADE	1		Deblock var. records (exits used)
ADG	1		Deblock var. records (no exits)
ADH	3 sort		Deblock fixed-length records
ADI	3 sort		Deblock var. records
ADJ	3 merge		Deblock (no exits)
ADL	2		Build tables in input buffer addresses
ADP	1		CRCX & OSCL: deblock fixed-length records up to 256 bytes (no exits)

CSECT Name	Used in Phase:	MO Diag	Purpose
ADQ	1		CRCX & OSCL: deblock fixed-length records >256 bytes (no exits)
ADR	1		CRCX & OSCL: deblock fixed-length records (exits used)
ADS	1		CRCX & OSCL: deblock var. records (exits used)
ADT	1		CRCX & OSCL: deblock var. records (no exits)
ADU	3 merge		Deblock (exits used)
ADX	3 sort		Deblock for read-forward tape, fixed-length records
AGA	1	N3.1	For tape, generate DCBs, IOBs, DCB addresses
AGB	2		Read tape backward
AGC	2		Read disk
AGD	3 sort		Read tape backward
AGE	3 sort		Read disk
AGF	3 merge		Open files
AGG	2	N3.2	For tape, generate DCBs, IOBs, DCB addresses
AGH	3 sort		Open files (and call checkpoint module)
AGI	1	N3.1	For disk, generate DCBs, IOBs, DCB addresses
AGJ	2	N3.2	For disk, generate DCBs, IOBs, DCB addresses
AGK	3 sort	N3.3	For disk, generate DCBs, IOBs, DCB addresses
AGL	2		For tape, read forward
AGM	3 sort		For tape, read forward
AGN	1	N3.1	OSCL: generate DCBs and IOBs
AMA	1		Contain messages for phase 1 assignment modules
AMB	2		Contain messages for phase 2 assignment modules
AMC	3 all		Contain messages for phase 3 assignment modules
AM1	0		Supply installed defaults
AOA	1		Sort fixed-length records, 'multiple' (not POLY)
AOB	1		Sort fixed-length records, 'single' (not POLY)
AOC	1		Sort var. records, 'multiple' (not POLY)
AOD	1		Sort var. records, 'single' (not POLY)
AOE	1		POLY: sort fixed-length records, 'multiple'
AOF	1		POLY: sort fixed-length records, 'single'
AOG	1		POLY: sort var. records, 'multiple'
AOH	1		POLY: sort var. records, 'single'
AOI	1		BALN (tape) sort algorithm
AOJ	1		POLY sort algorithm
AOK	1		BALN (disk) sort algorithm
AOL	0 (Opt) all	D3.4	Generate equals routine
AOM	0 (Opt) all	D3.4	Generate extract routine (part 1)
AON	1		OSCL sort algorithm
AOP	2 & 3 all		Merge, 'multiple'
AOQ	2 & 3 all		Merge, 'single'
AOR	2		BALN (tape) merge algorithm
AOS	2		POLY merge algorithm
AOT	2		BALN (disk) merge algorithm

CSECT Name	Used in Phase:	MO Diag	Purpose
AOW	1		CRCX & OSCL: initialization for fixed-length records, 'multiple'
AOX	1		CRCX & OSCL: initialization for fixed-length records, 'single'
AOY	1		CRCX & OSCL: initialization for var. records, 'multiple'
AOZ	1		CRCX & OSCL: initialization for var. records, 'single'
AO1	0 (Opt)	sort	Optimize disk unit assignment
AO2	0 (Opt)	sort	Optimize tape unit assignment
AO4	0 (Opt)	all D3.4	Generate extract routine (part 2)
AO5	0 (Opt)	all D3.4	Generate extract routine (part 3)
APA	1		Write tape
APB	1		Write disk
APC	1		Open files (and call checkpoint module); skip records on SORTIN
APD	2		Write tape
APE	2		Write disk
APF	3 merge	N3.3	Generate DCBs, DCB addresses
APG	1	N3.1	Allocate storage for I/O buffers, RSA, (three, control blocks, etc.)
APH	2	N3.2	Allocate storage for I/O buffers, control blocks, etc.
API	3 all	N3.3	Allocate storage for I/O buffers, control blocks, etc.
APJ	2		Open files (and call checkpoint module)
APK	3 sort	N3.3	For tape: generate DCBs, IOBs, DCB addresses
APL	1	N3.1	CRCX & OSCL: allocate storage for I/O buffers, RSA, control blocks, etc.
AP1	1		Specify area for DCB list for OPEN
AP2	2		Specify area for DCB list for OPEN
AP3	3		Specify area for DCB list for OPEN
BGB	0 (Def)	sort D3.4	CRCX: calculate B and G
CHK	1,2,3 sort		Checkpoint routine for sorting applications
DM4	All		Hexadecimal and decimal conversion
EX1	1		Act as link between user routines and program exits.
EX2	2		Routines which need linkage editing are linkage edited together with these modules:
EX3	3 all		phase 1 routines with EX1, and so on.
RBA	1	N4.11	CRCX & OSCL: block var. record
RBB	1	N4.11	Block fixed-length records with inline move
RBC	1	N4.11	Block fixed-length records with link to multiple move
RBE	1	N4.11	Block var. records with move
RBF	1	N4.11	Move var. records
RBG	2	N3.2	Block or deblock fixed-length records with in-line move (no exits)

CSECT Name	Used in Phase:	MO Diag	Purpose
RBH	2	N3.2	Block or deblock fixed-length records with link to multiple move (no exits)
RBI	2	N3.2	Block or deblock var. records with move (no exits)
RBJ	2	N3.2	Block or deblock fixed-length records (exits used)
RBK	2	N3.2	Block or deblock var. records (exits used)
RBL	3 all	N3.3	Block fixed-length records with in-line move (no exits)
RBM	3 all	N3.3	Block fixed-length records (exits used)
RBN	3 all	N3.3	Block var. records (no exits)
RBO	3 all	N3.3	Block var. records (exits used)
RBP	3 all	N3.3	Block fixed-length records with link to multiple move
RBT	2	N3.2	CRCX & OSC: block/deblock fixed-length records up to 256 bytes (no exits)
RBU	2	N3.2	CRCX & OSC: block/deblock fixed-length records >256 bytes (no exits)
RBV	2	N3.2	CRCX & OSC: block/deblock var. records (no exits)
RBW	2	N3.2	CRCX & OSC: block/deblock fixed-length records (exits used)
RBX	2	N3.2	CRCX & OSC: block/deblock var. records (exits used)
RBZ	1	N4.11	CRCX & OSC: block fixed-length records up to 256 bytes
RBY	1	N4.11	CRCX & OSC: block fixed-length records >256 bytes
RCA	All but 0 (Def)		Specify PPI area
RCB	All but 0 (Def)		System interface
RCD	0 (Def) all	D3.4	Scan MODS control statement
RCI	0 (Def) all		Identify input, output and work data sets and their characteristics
RCJ	0 (Opt) sort		Check disk capacity
RCK	0 (Opt) sort	D3.4	BALN (disk): optimize B and G
RCL	0 (Def) merge	D3.4	Merge-only optimization
RCM	0 (Def) all	D3.4	System interface
RCN	0 (Def) sort	D3.4	Calculate bin sizes
RCO	0 (Def) all		System interface controlling phase 0 (Def) (and linkage editor)
RCP	0 (Def) all	D3.4	List exit routines to be linkage edited
RCQ	0 (Def) all		Specify input area for control statements
RCR	0 (Def) sort	D3.4	Calculate B and G for tape sort and choose optimal technique; interpret MODS statement
RCR		D3.4	Free storage between phases
RCU	1,2,3 all		Contain error messages for phase 0
RCV	0 (Def+Opt) all		System interface for processing records
RCW	1,2,3 all		Contain messages for MODS card errors
RCX	0 (Def) all		Control of phase 0 (Opt)
RCZ	0 (Opt) all		
RC1	0 (Opt) all	D3.4	Move CPI information to PPI
RC2	0 (Def) all		Calculation for extract
RC3	0 (Def) all		Contains messages for MODS card scanning

CSECT Name	Used in Phase:	MO Diag	Purpose
RC4	0 (Opt) sort		Calculate and optimize disk work areas
RC6	1	N3.1	Determine modules needed in phase 1
RC7	2	N3.2,N3.1	Determine modules needed in phase 2
RC8	3 all	N3.3	Determine modules needed in phase 3
RC9	1,2,3 all	N3.3, N3.2, N3.1	Load necessary modules for each phase
RDB	1	N3.1	Deblock fixed-length records with in-line move (no exits)
RDC	1	N3.1	Deblock fixed-length records with link to multiple move (no exits)
RDD	1	N3.1	Deblock fixed-length records (exits used)
RDE	1	N3.1	Deblock var. records (exits used)
RDG	1	N3.1	Deblock var. records (no exits)
RDH	3 sort	N3.3	Deblock fixed-length records (for disk and read-backward tape)
RDI	3 sort	N3.3	Deblock var. records
RDJ	3 merge	N3.3	Deblock
RDL	2		Set up deblock area
RDP	1	N3.1	CRCX & OSL: deblock fixed-length records up to 256 bytes (no exits)
RDQ	1	N3.1	CRCX & OSL: deblock fixed-length records up to 256 bytes (no exits)
RDR	1	N3.1	CRCX & OSL: deblock fixed-length records (exits used)
RDS	1	N3.1	CRCX & OSL: deblock variable records (exits used)
RDT	1	N3.1	CRCX & OSL: deblock var. records (no exits)
RDU	3 merge	N3.3	Deblock (exits used)
RDX	3 sort	N3.3	Deblock fixed-length records (for read-forward tape)
RGB	2	N3.2	Read tape backwards
RGD	3 sort	N3.3	Read tape backwards
RGE	3 sort	N3.3	Read disk
RGF	3 merge		Indicate input end-of-file
RGL	2	N3.2	Read tape forward
RGM	3 sort	N3.3	Read tape forward
RGV	1 sort, 3 merge	N3.1, N3.3	VSAM read
RMA	1		Contain messages for ph1 running modules
RMB	2		Contain messages for ph2 running modules
RMC	3 all		Contain messages for ph3 running modules
ROA	1	N4.11	Sort fixed-length records, 'multiple' (not POLY)
ROB	1	N4.11	Sort fixed-length records, 'single' (not POLY)
ROC	1	N4.11	Sort var. records, 'multiple' (not POLY)
ROD	1	N4.11	Sort var. records, 'single' (not POLY)
ROE	1	N4.11	POLY: sort fixed-length records, 'multiple'
ROF	1	N4.11	POLY: sort fixed-length records, 'single'
ROG	1	N4.11	POLY: sort var. records, 'multiple'

CSECT Name	Used in Phase:	MO Diag	Purpose
ROH	1	N4.11	POLY: sort var. records, 'single'
ROI	1	N4.12	BALN (tape): sort algorithm
ROJ	1	N4.12	POLY: sort algorithm
ROK	1	N4.12	BALN (disk): sort algorithm
RON	1	N4.12, N3.2	OSCL: sort algorithm; initiate checkpoint operations
ROP	2 & 3 all	N3.2, N3.3	Merge records 'multiple'
ROQ	2 & 3 all	N3.2 N3.3	Merge records, 'single'
ROR	2	N3.2	BALN (tape): merge algorithm
ROS	2	N3.2	POLY: merge algorithm
ROT	2	N3.2	BALN (disk): merge algorithm
ROW	1		CRCX & OSCL: sort fixed-length records, 'multiple'
ROX	1		CRCX & OSCL: sort fixed-length records, 'single'
ROY	1		CRCX & OSCL: sort var. records, 'multiple'
ROZ	1		CRCX & OSCL: sort var. records, 'single'
RPA	1	N4.12, N3.2	Write tape
RPB	1	N4.12	Write disk
RPC	1	N3.1	End-of-phase housekeeping (not CRCX or OSCL)
RPD	2	N3.2	Write tape
RPE	2	N3.2	Write disk
RPF	2	N3.2	End-of-phase housekeeping (not CRCX or OSCL)
RPG	3 all	N3.3	Open output; end-of-phase housekeeping procedures
RPM	1 & 2	N3.2	OSCL: end-of-phase housekeeping
RPV	3 all	N3.3	VSAM write
8BN	3 all	N3.3	Block var. spanned records (no exits)
8BO	3 all	N3.3	Block var. spanned records (exits used)
8CI	0 (Def) all		Contain tables and constants for RCI
8CK	0 (Opt) sort		BALN (disk) timing estimate routine
8CR	3 merge		Checkpoint routine at end of output volume
8DJ	3 merge	N3.3	Deblock variable-length spanned records (no exits)
8GB	2	N3.2	CRCX read
8GC	3 sort	N3.3	CRCX read
8ON	1	N4.12, N3.2	CRCX sort algorithm
8PA	1 & 2	N4.12, N3.2	CRCX write
8PM	1 & 2	N3.2	CRCX end-of-phase housekeeping
9BN	3 all		Block var. spanned records, no exits (assignment)
9BO	3 all		Block var. spanned records, exits used (assignment)

CSECT Name	Used in Phase:	MO Diag	Purpose
9DJ	3 merge		Assignment deblock variable-length spanned records (no exits)
9GB	2		CRCX read assignment
9GC	3 sort		CRCX read assignment
9GN	1	N3.1	CRCX: generate DCBs, OBs, ECBs, alternate CCW pointers
9ON	1		CRCX algorithm assignment
9PA	1 & 2		CRCX write assignment

Section 5: Data Areas

The program makes extensive use of a large data area. For Blockset applications the area is called COMMON, and its layout is defined in the DSECT COMMON, for Peerage and Vale applications the area is called COMMA, and its layout is defined in the DSECT ICECOMMA. For other applications the information in COMMA is moved in phase 0 to a 'control phase information area', the CPI, and thence to a 'phase-to-phase information area', the PPI, the DSECT for which resides in module ICERCA. How to list COMMA is described in Section 6. The CPI and PPI are described in detail below together with Module ICEAM1, which contains CSECT ICEAM1, which contains the default values specified when the program was installed.

For the CPI and PPI a listing is given showing the position, length, name and contents of each field. For the PPI a 'map' is also provided, as well as an index.

If you know the name of a field in the CPI or the PPI, but not its position, you can find its displacement from the cross-reference tables in Section 6.

| Blockset Area (COMMON)

| This area is allocated by ICEMAN and is used by all Blockset modules.
| It is described in the DSECT COMMON. The program uses register 13 as a
| base register for COMMON.

| COMMON PRINTOUT

Peerage and Vale Communication Area (COMMA)

- | This area is allocated by ICEDEF and is used by all Peerage and Vale technique modules. It is described in the DSECT ICECOMMA. The program uses register 13 as a base register for COMMA.
- | It can be listed as described in Section 6, 'Debugging Aids'. Such a listing gives not only field definitions (name, position, length, description), but also current contents.

Control Phase Information Area (CPI), Conventional Techniques

The program's Control Phase Information Area is set up by ICERCO and ICERCM. It is used for the communication of parameters that are needed by the general assignment routines. It is expanded into the PPI (Phase-to-Phase Information Area) by ICERC1 in the Optimization Phase.

DISPLACEMENT DEC	(HEX)	SIZE	FIELD NAME	DESCRIPTION MEANING/USE
0	(0)	72	ICERC5	Register area
72	(48)	72		Control Field Information
72	(48)	2	CPINUMCF	No of control fields
74	(4A)	72	CPIPCFxx	12 entries in the form:
		3		- Position
		2		- Length
		1		- Format + sequence
146	(92)	8	CPISW1	Switch of 64 Bits (See PPISW1 for details)
154	(9A)	4	CPILAB09	Output buffers:
			(Byte 1)	No of ph2 output buffers
			(Byte 2)	No of ph3 output buffers
			(Bytes 3-4)	Size of ph3 output buffers
158	(9E)	2	CPINWKU	No of work units
160	(A0)	2	CPIP1ASZ	Ph1 assignment size
162	(A2)	2	CPIIPBLK	Input blocking
164	(A4)	2	CPIFFF	Displacement of F field (used by extract routine)
166	(A6)	2	CPIPBUFF	Displacement of packing buffer
168	(A8)	2	CPIP2ASZ	Size of ph2 assignment modules
170	(AA)	2	CPIP3ASZ	Size of ph3 assignment modules
172	(AC)	2	CPIOPBLK	Output blocking
174	(AE)	2	CPIBUF23	No of buffers (ph2,3)
176	(B0)	2	CPISRIBL	B (blocking used on work areas)
178	(B2)	2	CPIRCDL1	1, from RECORD stmt (LENGTH)
180	(B4)	2	CPIRCDL2	1 ₂ from RECORD stmt (LENGTH)
182	(B6)	2	CPIRCDL3	1 ₃ from RECORD stmt (LENGTH)
184	(B8)	2	CPIRCDL4	1 ₄ from RECORD stmt (LENGTH)
186	(BA)	2	CPIRCDL5	1 ₅ from RECORD stmt (LENGTH)
188	(BC)	2	CPILAB03	Size of ph1 input buffers
190	(BE)	2	CPILAB07	Output buffer information
192	(C0)	2	CPIPGCSZ	Size of area used by extract rtn
194	(C2)	2	CPIBINSZ	Bin size
196	(C4)	3	CPISKPRD	Count of skipped records
199	(C7)	3	CPIATP1E	Addr of invoking pgm's ph1 exit
202	(CA)	3	CPIMODEX	Exits Activated (see first 3 bytes of PPIMODEX for details)
205	(CD)	3	CPIATP3E	Addr of invoking pgm's ph3 exit
208	(D0)	3	CPITAVLC	Size of available core, ph1
211	(D3)	3	CPIFILSZ	Value of FILSZ/SIZE parameter
214	(D6)	3	CPISRIG	G (Capacity of RSA, in records)
217	(D9)	3	CPISIRG	Size of interblock gap (tape wk)
220	(DC)	3	CPIP1GC	Size of ph1 work area
220	(DC)	3	CPIP1RSZ	Ph1 running modules size
223	(DF)	3	CPIP2GC	Size of ph2 work area
223	(DF)	3	CPIP2RSZ	Ph2 running modules size
226	(E2)	3	CPIP3GC	Size of ph3 work area
226	(E2)	3	CPIP3RSZ	Ph3 running modules size
229	(E5)	1	CPIBUF1	No of ph1 buffers
230	(E6)	1	CPIMRGMX	Maximum merge order

DISPLACEMENT DEC	(HEX)	SIZE	FIELD NAME	DESCRIPTION MEANING/USE
231	(E7)	1	CPIMRGAL	Alternate merge order
232	(E8)	3	CPILINK	Link Edit Info for exit rtns
		xxxx xxxx	(Byte 1)	Exits in order as for PPIMODEX:
		xxxx xxxx	(Byte 2)	1=Routine was link edited,
		x...	(Byte 3)	0=Not edited (via the program)
		.1..		E11 routine edited separately
		..1.		E21 routine edited separately
		...1		E31 routine edited separately
		 1...		Linkage editing was carried out
		1..		VSAM output not reusable
		1.		Linkage edit error
		1		VSAM release 1 in system
235	(EB)	3	CPIADDCF	When more than 12 ctl fields: addr of additional information
238	(EE)	8	CPISORCE	DDname of user mod library
246	(F6)	4	CPIDDSRT	4 chars to replace SORT in DDnames (fr param list when pgm invoked)
250	(FA)	2	CPIDCBIN	Size of SORTIN DCB
252	(FC)	2	CPIDCBOU	Size of SORTOUT DCB
254	(FE)	4	CPIXCAP	OSCL:RMAX (max no of bytes/reel) Otherwise: Capacity of interm. storage (in records)
258	(102)	16	CPIDDEV	Device inf: words 2-5 fr DEVTYPE macro (used by ICERCI)
274	(112)	3	CPIAUENT	Addr of user exit name table
277	(115)	1	CPISUENT	Size of user exit name table
278	(116)	8	CPIMSGDD	Message DDname if not SYSOUT
286	(11E)	1	CPIRECFM	User record format for ph3
287	(11F)	8	CPIJOBNM	Jobname
295	(127)	8	CPISTPNM	Stepname
303	(12F)	1	CPISW2	Switch of 8 Bits
		1...	CPIFSEON	FILSZ given with exact value
		.1..		Exec sort with ABEND option
		..1.		AQ control fields present
		...1		Preserve order of equals
		 1...		VSAM input
		1..		KSDS VSAM output
		1.		ESDS VSAM output
		1		SIZE (MAX) used
306	(130)	2	CPIMXCOL	Rightmost col included in any control field
308	(132)	1	CPIDEVCD	Device code for unit with RPS
309	(133)	256	CPIAQTAB	Translate table for use with AQ control fields

Phase-to-Phase Information Area (PPI), Conventional Techniques

The Phase-to-Phase information area (PPI) is a communication area for all modules of the conventional sort/merge program. It is created during Phase 0 and resides in main storage throughout execution. It is not executable, and has the CSECT name ICERCA.

The program uses register 13 as the base register for the PPI. Reference to any field within the area can be made by adding the appropriate displacement to the contents of register 13. The displacement for each field within the PPI appears in decimal and hexadecimal form in the description which follows Figure 15.

Abbreviations

Mult	means a multiple compare routine is used to compare records;
No mult	means it is not;
Extract	means an extract routine is used to compare records.
Fix	means records are fixed length;
Var	means records are variable length.

Index to PPI

The following index covers PPI fields only. For any given subject, it shows the name of the PPI field referenced, plus the field's displacement from the beginning of the PPI area, in hexadecimal.

Since all fields begin with the letters 'PPI', these letters are omitted.

When the reference is to a field which occupies a whole number of bytes, the displacement is shown in whole bytes. When the reference is to one or more bits within the field, the reference is given in the form 'bytes.bits'. For example, the field PPISW1 is at displacement 560. A reference to 'SW1,561.0' therefore means the first bit (bit 0) of the second byte in the field.

Ascending
 - order for SORTOUT SW1,563.2
 - order for merge pass SW1,563.3

Assignment modules
 - size in ph1 P1ASZ,76

BALN (disk) technique
 - being used SW1,561.2
 - on 2314 SW1,566.?
 - disk end addresses ENDAR,424
 - count of strings on each work area SEQCT,592
 - alternate merge order MRGAL,660
 - optimum merge order MRGOP,662
 - pointer to table of formatted tracks FTTAB,1084

BALN (tape) technique
 - being used both SW1,560.4
 and SW1,561.1
 - count of strings on each work area SEQCT,592
 - current pass odd or even SW1,565.2

Blocking
 - of input IPBLK,88

Buffer, packing
 - displacement of PBUFF,104

Buffers
 - size of input buffer LAB03,685
 - no. of input buffers LAB03,684
 - size of output buff. LAB07,689
 - no of output buffs LAB07,688
 - alignment SW1,563.?
 - no of ph1 buffers BUF1,92
 - no of ph2&3 buffers BUF23,628
 - addr of input buffer table LAB02,724
 - addr of ph1 buffer pool LAB06,736
 - addr of merge-only buffer pool LAB06,736

Channels
 - types and combinations of channels SW1,565.3+4
 - tape switch (or alternative channel option) present SW1,564.?
 - >1 channel available SW1,564.?

Checkpoint
 - being used SW1,562.7
 - module address CHKAD,1060

Communication area
 for user USER,672

Comparison techniques:
 - multiple techn used SW1,562.?

- extract techn used SW1,562.?
 (see also F field)
 - addr of compare rtn AXERT,668
 - addr of 2nd move rtn for multiple techn MOVEQ,1112

Control blocks
 - addr of DCB table STDCB,760
 - addr of IOB table STIOB,768
 - DCB addr of SYSLMOD user library SORCE,788
 - DCB addr of SORTLIB SLIB,796
 - size of SORTIN DCB DCBIN,1064
 - size of SORTOUT DCB DCBOU,1066

Control fields
 - definitions: field1 PCF01,114
 field2 PCF02,120
 field3 PCF03,126
 .
 .
 field12 PCF12,180
 further fields--
 definitions pointed to by ADDCF,1048
 - no of fields NUMCF,112
 - rightmost column included in ctl fld MXCOL,1104
 - 'E' type present SW1,564.0
 - 'A' type present SW1,563.2
 - 'D' type present SW1,563.2

Control statements
 - SORT present SW1,564.1
 - MERGE present SW1,564.2
 - RECORD present SW1,564.3
 - MODS present SW1,564.4
 - RECORD absent or incorrect SW1,564.5

Control word
 - length of LEXFD,676

Counter (blocks)
 - addr of count table SBLCT,764

Counter (records)
 - total records entering the phase RCDCT,588
 - records inserted INSCT,584
 - records skipped SKPRD,80
 - records deleted DELCT,580
 - records written to work units (ph2) COUNT,576
 - records written to SORTOUT (ph3) COUNT,576
 - records deblocked fr SORTIN (OSCL, ph1) COUNT,576

Counter (strings)
 - no of strings to each work area (BALN only) SEQCT,592

CRCX technique		- given exactly	SW2,571.0
- being used	SW1,565.?	- value of	FILSZ,604
- merge pass to follow	SW1,566.?	Final merge (phase 3)	
Data chaining		- size of work area	P3GC,700
- none	SW1,561.3	- no. of bins (var)	BDSVA,745
- input	SW1,561.4	- addr of next bin (var)	BDSVA,744
- output	SW1,561.5	- addr of input buffer	
DCB table		table	BDSVA,744.1-3
- address of	STDCB,760	- addr of move list (fix)	BDSVA,745
Descending		- return addr to RCV	ADSSC,804
- order for SORTOUT	SW1,563.2	- pointers to modules used:	
- order for merge pass	SW1,563.3	RPG	WRT,840
Disk sort		read	RD,856
- addr of disk directory	DIRAD,280	open list	OPEN,944
- no of SORTWK areas	NDSKA,680	deblock	DEB,816
- no of blocks/track	BPTRK,682	merge	NET,824
- no of tracks/cyl.	TPCYL,1068	block	BLK,832
- no of directory blocks		messages (assignment)	AMC,936
per track	DPTRK,1070	messages (running)	RMC,923
- no of bytes/track	CPTRK,1072	Fixed-length records (fix)	
- RPS feature used for		- being used	SW1,560.0
SORTWK	SW1,565.?	Generated core, permanent	
- device code for unit		- size of	PGCSZ,96
with RPS	DEVCD,1106	- address of	ARGC,1074
- disk addresses,ph1,2,3	DSKED,152	- address of network table	
- disk starting addr	STAR,288	in area	NETAR,1080
End of file		GETMAIN	
- reached for OSCL	SW1,563.7	- addr of table of addr	GETMN,780
Exits		- addr of table of sizes	GETSZ,784
- none activated	SW1,561.6	Initiation of the program	
- some activated	SW1,561.7	- how achieved	SW1,563.5
- those activated	MODEX,568	Input buffers	
- pointers to routines:		- no & size of buffers	LAB03,684
for E11	X11,952	- addr of buffer table	LAB02,724
for E21 or E31	Xx1,960	Input DCB	
for E15	X15,968	- size of SORTIN DCB	DCBIN,1064

Module ICEAM1: Generated Defaults

The option values generated when the program is installed are stored in module ICEAM1. The format of the module is shown below. Values underlined are generated by default if no specification is made when the program is installed. The generated values can be changed by use of the IMASPZAP, HMASPZAP (VS1) or AMASPZAP (VS2) Service Aid Program.

Note: If you have changed the generated values and reenterable modules are placed resident, you have to re-IPL the operating system to activate the changes. For SVS/MVS specify option CLPA when you re-IPL.				

Section 6. Debugging Aids

This section is intended to help you if Sort behaves in an unexpected way, and you want to localize the problem and if possible solve or bypass it. It contains the following subsections:

- How to decide whether a problem is due to a program error.
 - General considerations when an error has been located.
 - How the microfiche are organized.
 - Adding a temporary change to the maintenance area.
 - How Sort uses registers.
 - How to read a dump to find DCBs and IOBs for SORTIN, SORTOUT, and SORTWK.
 - Various uses of the DEBUG control statement.
 - Explanations of the diagnostic messages.
 - Explanation of program dumps.
 - Finding an object module in a storage dump.
 - Message-to-module cross reference. How to find messages in the code.
 - Cross references showing the displacement of each field in the common data areas (COMMON, COMMA, CPI, and PPI) for the various techniques.
- Other diagnostic aids are provided in Section 3, where the phase structures are given; Section 5, which shows the layout of some important control blocks; and Appendix A, showing which modules activate the various program exits.

Defining Problem Cause

If the program is unable to successfully complete sorting or merging, you will certainly get one or more program messages, and possibly also an ABEND code.

The OS/VS Sort/Merge Programmer's Guide gives explanations of the various program messages, and suggestions as to how to cope with them. It is assumed that you have exhausted those explanations before turning to this section.

| IS THIS A PROGRAM ERROR?

| Your first task is to decide whether or not the problem is due to an error in Sort code.

| If your installation has just installed a new release or PTF level of Sort, it is worth checking that any necessary additional alias names have been added to module ICEMAN. If they have not, mixed levels of program modules can be executed, which can give rise to unpredictable abnormal terminations.

| Otherwise, if Sort is run alone in its region, problems are unlikely to arise from the environment. If no routines of yours were invoking Sort, or being used at program exits, you can therefore work on the assumption that you have found a program error, and turn to the section 'Bypassing the Problem' below.

| However, if you are invoking Sort from a program of your own, or if you are using routines at program exits, you will need to eliminate your own programs as sources of error. In the example in Figure 16, for instance, an exit (E15) is being used.

```

| Figure 16. A Sample Set of Messages

| POTENTIAL PROBLEMS WITH ROUTINES AT PROGRAM EXITS

| Use of Registers

| The first thing to check with your routines is that they observe the standard linkage conventions. If, for example, they corrupt register 12, results are unpredictable but almost certain to result in an ABEND of some kind, because Sort uses register 12 as its main base register.

| Check, too, that you are not using registers for loading or storing that are accidentally causing overlay of sort code or work areas. If this happens Sort could work without errors with one technique, but fail with another.

Space

The next thing to check is whether your routines are trying to use more space than you have allocated to them. Have you installed a new operating system release since the last time you used these routines? Each time you use an OPEN macro, for example, your program may take buffer space; but the amount it tries to take will depend upon such factors as the current release of the operating system.

A change of operating system could therefore lead to an ABEND in your own routine; or it could lead to too little space being left for Sort.

You can see whether too little space was left for sorting by studying the information in message ICE093I. As shown in Figure 16, the third field in the 'MAIN STORAGE' parameter will tell you how much was actually left for Sort after your own routines had taken what they needed, in a region or partition of only 256K. Since in the example the input block size is large, the 48,528 bytes left are not enough.

Similar situations can occur if Sort is dynamically invoked using the MAX option, and a fairly large reserved value is passed to Sort or taken by default.

Another problem could arise if the E15 routine issues a GETMAIN without a corresponding FREEMAIN at the end. This problem can be caused indirectly, for example by leaving a data set open so that a buffer pool remains reserved.

Record Contents

If the output records do not appear to contain the same data as the input records, and either E15 or E35 has been used, check that your routine is handling register 1 correctly; especially, check that it is correct on return to Sort.

If for example you first load register 1 and then restore all registers (including register 1), it will probably have the wrong contents.

Equally, if you first restore all registers and then try to load register 1 from a corrupted base register, you will almost certainly pass the wrong information to Sort.

POTENTIAL PROBLEMS WITH INVOKING PROGRAMS

Space can also be a problem when you invoke Sort from another program, especially if you are using SIZE=MAX and invoking exit E15 or E35 (or, from COBOL, using an Input or Output procedure).

If you do this, and particularly if you open a file in your exit routine, check that you specify a sufficiently large amount of reserved storage.

Considerations when an Error has been Located

When you have pinpointed an error to a particular module, it is always worth doing a RETAIN search to find out whether the problem is already known. If the problem itself has not been reported, you can search for other APAR fixes to the failing module, and apply them if appropriate.

If this procedure fails, you have the choice between trying to fix the problem, and trying to bypass it. You will then also want to report the problem.

WHEN NOT TO WASTE TIME ON REPAIR

Some modules contain extremely complex code. Attempts at field repair can be expected to take an unreasonable amount of time.

The following load modules are particularly unsuitable candidates for field repair:

	ICEIPUT	ICEIPVT	ICEOPUT	ICEOPVT
	ICEKPUT	ICEKPVT	ICEPAR	
	ICEKPUS	ICEKPVS	ICERED	

BYPASSING A PROBLEM

The simplest way of bypassing a problem in the program is to force it to use a different technique. Message ICE092I or ICE093I will tell you which sorting technique has been used.

You can use the DEBUG control statement, described later in this section, to force the use or non-use of a specific technique. Alternatively, if the problem is in the Blockset technique (the newest in the program), you can 'turn off' that technique altogether by including an OPTION statement with the parameter NOBLKSET.

| REPORTING A PROBLEM

| You have two alternative means available for reporting a problem: an incident report, or an APAR.

| Submitting an Incident Report

| Generally, central service needs the following information in a RETAIN incident entry:

- | • Symptom
- | • Was SORTIN or SORTOUT DD statement present? If so, list the DCB attributes.
- | • Was Sort invoked from another program? If so, try to list the contents of the parameter list passed. See the OS/VS Sort/Merge Programmer's Guide for parameter list format. At entry to Sort register 1 must point to the parameter list. Note, however, that (except with a standard disk sort) the initial contents of register 1 are lost towards the end of Phase 0.
- | • Was Sort invoked via JCL? If so, list all the program control statements used.
- | • List Release and PTF levels, and if possible the APAR fixes applied since the last PTF.
- | • Give the number of SORTWK data sets used, and their unit type.
- | • If message ICE092I or ICE093I was issued, give its contents.
- | • If you have a dump, list the Sort module(s) in storage when the program failed, and the displacement into the failing module at which the abend occurred.

| Submitting an APAR

| In addition to the information requested on an APAR form, you should supply the following information:

- | • A dump from the failing run of Sort.
- | • A list of PTFs applied, and if possible the APAR fixes applied since the last PTF.
- | • Source code (Assembler or compiler listings) and object code for any user routines and/or invoking program.
- | • A listing of the JCL.
- | • A copy of the input file(s) in machine-readable form.
- | • A list of program control statements used.

- A list of the generation options selected, which can be produced by using IMASPZAP (or an equivalent program) to dump the contents of module ICEAM1.

Microfiche Organization

For Peerage and Vale each load module is on one fiche, with the same name as the load module name. For example, module ICEDEF is completely contained on a fiche called ICEDEF.

Blockset has several fiches for each load module. Each object module is on a separate fiche. For example, load module ICEMESI consists of five object modules (ICEMESI, ICEMESS, ICEEXII, ICEMSGI, and ICESUBS), and is on five fiches with those names, as shown in Figure 17.

Figure 17. Microfiche for Load Module ICEMESI

The other techniques have one fiche per load module, except for modules ICERCM and ICERCZ. These two modules have an overlay structure, and are shown with one fiche per object module. Section 3 gives further details of module organization under the heading 'Phase Structures'.

| Adding a Temporary Change to the Maintenance Area

| Every new Sort module has a maintenance patch area.

| For Peerage and Vale the area is included in each load module. It is 100 bytes long, or 5% of the size of the module, and is at the end of the module. It is usually addressable by using register 11 plus the appropriate displacement (which can be calculated from the microfiche), and generally starts with the label PATCH in the source code.

| Blockset has a maintenance patch area of at least 64 bytes in each object module. It can be found in the fiche by looking for the label PATCH.

| The other, older techniques do not have patch areas. Instead you can use the EXPAND facility of the linkage editor to create one at the end of a module, if required.

| To use a patch area, first verify that it contains all zeros. Then use the appropriate utility (IMASPZAP, HMASPZAP, or AMASPZAP) to put in the required change.

| If the Sort reenterable modules are in the LPA library, do not forget to re-IPL with the CLPA option.

| How Sort Uses Registers

| In addition to the conventions described in Appendix D, the Peerage/Vale techniques make extensive use of certain internal register conventions. They are shown in Figure 18.

Register	Use
0 - 5	Work registers
6	Current RSA pointer
7	Pointer to current record in input buffer for SORTIN or SORTWK
8	Pointer to current record in output buffer for SORTWK or SORTOUT
10	Internal return register when branch-and-link to sub-routines is used
11	Secondary base register
12	Primary base register
13	Pointer to the common area (COMMA or COMMON)
14 - 15	Work registers

| Figure 18. Use of Registers by Peerage/Vale Techniques

| Finding DCBs and IOBs for SORTIN, SORTOUT, SORTWK

| This subsection describes how to locate the I/O control blocks in a system dump, for the standard disk techniques.

| The first step is to verify, from message ICE092I or ICE093I, which of the standard techniques has been used.

| You should then find the common area. Look at the address pointed to by register 13, and check whether the first word contains the characters 'SM1'. If it does, register 13 is intact, and can be used when calculating offsets. If it does not, and you are certain the Sort program is being used, then register 13 has been corrupted. However, you can still find the common area by looking for the eyecatcher 'SM1' with which it begins.

| BLOCKSET TECHNIQUE

| SORTIN and SORTOUT Control Blocks

| Figure 19 shows an example of interpreting a system dump for Blockset.

| The procedure for finding input and output control blocks is as follows:

- | 1. Look in COMMON at label COMINDCB, which is at register 13 + X'154'. There you will find a pointer to the SORTIN DCB.
- | 2. The SORTOUT DCB pointer is at label COMUTDCB, at register 13 + X'158'.
- | 3. There is no pointer from the DCBs to the corresponding IOBs, because EXCP is used for access. However the IOBs are in the same areas as the corresponding DCBs, at displacement X'48' from the start of the DCB.
- | 4. A fullword at IOB + X'14' points back to the DCB.

| SORTWK Control Blocks

| The procedure for finding SORTWK control blocks is as follows:

- | 1. Look in COMMON at label COMWKDCB, at register 13 + X'15C'. This is a pointer to the DCB list.
- | 2. Follow the pointer to the SORTWK DCB list. Each element in the list is a pointer to a DCB. The last element in the list has the first bit on.
- | 3. As for SORTIN and SORTOUT, the access method used is EXCP. The IOB for each work area follows the corresponding DCB, at DCB start address + X'48'.

Figure 19. Locating Control Blocks in a Dump with Blockset

| PEERAGE AND VALE TECHNIQUES

| The layout of all Peerage and Vale internal work I/O control blocks can
| be found in the microfiche for modules ICEMON and ICEDEV.

| SORTIN and SORTOUT Control Blocks

| First check which access method has been used. If EXCP was used, you
| will have received message ICE084I; otherwise (if SAM was used) you will
| not.

- | 1. Field CSORTIN in COMMA, at register 13 + X'5FC', points to the
| SORTIN DCB.
- | 2. Field CSORTOUT, at register 13 + X'600', points to the SORTOUT DCB.
- | 3. If EXCP is used, most I/O information is in a storage area, subpool
| 0, with label OBSBLOCK. See Figure 20. A pointer to this area is
| in ICECOMMA at label COBSBLOK, at register 13 + X'7E4'.

| At OBSBLOK + X'8' there is an eyecatcher consisting of the
| characters 'OBSBLOCK'.

| The layout of OBSBLOCK is given in the microfiche ICEOBS and
| ICEXCP.

- | a. In one of them, find the offsets to label OBSIOBP.
- | b. Add the value of the EQU' (OBSIOBP) to the address of OBSBLOCK
| (taken from register 13 + X'7E4', as described above). This
| gives the address of the IOB: if you are in Phase 1 it will be
| the SORTIN IOB; in Phase 3 it will be the SORTOUT IOB. If you
| are not sure of the phase, check the DCBs to see which one is
| open.

Figure 20. Locating SORTIN and SORTOUT Control Blocks with EXCP in a Dump with Peerage and Vale

- | 4. OBSBLOCK also contains read/write and check simulators, used to
| simulate SAM access methods. The SORTIN and SORTOUT DCBs contain
| the addresses of the simulators, at DCB + X'30' and DCB + X'34'
| respectively.
- | 5. After a read or write macro has been used to invoke a simulator,
| and before the subsequent check macro is issued, there are also
| valid pointers from OBSBLOCK to the DECB at the beginning of each
| buffer. See Figure 20. The address of the pointer list (a list of
| fake IOBs, or FIOBs) is at label OBSIFFIO. To find a DECB:
 - | a. Look in the fiche for ICEOBS or ICEXCP, and find label
| OBSFIOBP.
 - | b. Add the value of the EQU(OBSFIOBP) to the address of OBSBLOCK,
| taken from register 13 + X'7E4'.
 - | c. The result is the address of a pointer to the first FIOB.
 - | d. The other FIOBs follow consecutively, each X'48' bytes long on
| a doubleword boundary.
 - | e. The DCB NCP value tells how many valid FIOBs there are.
 - | f. The FIOB plus 4 points to the DECB.

SORTWK Control Blocks

Figure 21. Locating SORTWK Control Blocks in a Dump with Peerage/Vale

The procedure to find a work IOB is as follows:

1. Look in COMMA at label CPAGELOC, at register 13 + X'4D4'. This field contains a pointer to a control block called BUFFAR.
2. Follow the pointer to BUFFAR. At BUFFAR + X'4C' you will find a pointer to a control block called PAGED.
3. Follow the pointer to PAGED. At PAGED + X'4AC' is an area, WIOB, containing five control blocks.
4. WIOB + X'14' contains the IOB. IOB + X'14' points to the DCB.
5. The WIOB control blocks are each X'80' bytes long, and follow each other consecutively.

You can also go straight to the DCB, as follows:

1. The field CSORTWK in COMMA, at register 13 + X'61C', contains a pointer to the SORTWK DCB list. Each word in the list points to a work DCB, which forms part of a control block called WORKD. The last word in the list has the first bit on.

The DEBUG Control Statement

This statement is only valid when the program meets the criteria for the standard disk techniques. If it is supplied under other circumstances it is ignored.

The statement is not intended for regular use; only the first two parameters are of general interest. The other parameters can be used to provide a temporary bypass, or to supply detailed information on program execution for use when optimizing or debugging the standard disk sort.

DEBUG can be passed to an invoked sort by means of the SORTCNTL DD statement, for example:

```
//SORTCNTL DD *  
DEBUG BSAM
```

This DD statement is described in full in the OS/VS Sort/Merge Programmer's Guide. Note that the DD name might not always be SORTCNTL, because the first four letters of Sort's special DD statement names can be changed for an invoked application. It might, for example, need to be called //TESTCNTL instead. See the chapter in the Programmer's Guide on invoking Sort from another program. The Blockset techniques will not be used when the DEBUG control statement is used with a SORTCNTL DD statement.

SYNTAX

```
[label] DEBUG  ABEND      ,DUMP      [,PEERVALE] ,BALN
                NOABEND   ,NODUMP                      ,CRCX
                [,CLOCK] [,FLAG] [,CTRx] [,BSAM]
```

ABEND
NOABEND

Overrides the generated default for action to be taken when the program encounters an uncorrectable error.

DUMP and NODUMP

Recognized but ignored.

PEERVALE

With a disk sort one of the three standard techniques (Blockset, Peerage, or Vale) is normally used. If you have encountered a problem when using Blockset (see message ICE092I or ICE093I), you can temporarily bypass this technique by specifying PEERVALE, thus forcing Peerage or Vale to be used.

BSAM

With the disk sort techniques Peerage and Vale, normally the EXCP access method is used for SORTIN and SORTOUT. If you encounter a problem related to this I/O activity you can temporarily bypass it by specifying BSAM.

BALN
CRCX

With a disk sort you can use this parameter to force either the balanced (BALN) or crisscross (CRCX) disk sorting technique and therefore bypass the standard disk sort techniques used by the program. If either BALN or CRCX is forced then the following restrictions apply:

- At least three work data sets on the same type of device are needed, with amount as specified in OS/VS Sort/Merge Programmer's Guide. Mixed device types are not allowed.
- Maximum record length must be less than work device track length.
- Allocation must be contiguous (the CONTIG parameter is required), and only primary extents will be used.
- Six or more work data sets are required for the CRCX technique.
- For SORTWKnn: nn can be any number from 01 to 32. The first number must be 01 and the others must follow consecutively with no gaps.
- Unused work space will not be released; the RLSE parameter must not be specified.

	CLOCK	Instructs the program to measure elapsed and CPU
	(only Peerage	times for the different phases.
	and Vale)	
	FLAG(0)	Instructs the program to print information messages
	(only Peerage	(ICE120-125). These messages are listed under
	and Vale)	'Messages Produced by Using the DEBUG Statement'.
	CTRx=value	Specifying this parameter will force Peerage or Vale
		to be used. The program will keep a count of the
		input or output records. When the count reaches the
		value specified the program will ABEND, and a
		formatted dump will be printed.
		The numbers that may be assigned to x are:
	2	Count of input records being moved from the input
		buffer.
	3	Count of output records being moved to the output
		buffer.
	4	Count of input records inserted by E15.
	5	Count of output records deleted by E35.
	<u>Note:</u> When the count reaches 'value', the program will ABEND. It will	
	also terminate with message ICE025A if the 'value' is a number greater	
	than the number of input records.	

MESSAGES PRODUCED BY USING THE DEBUG CONTROL STATEMENT

Messages ICE120-125 are issued if the DEBUG statement is supplied with the appropriate parameters FLAG (a) (only for Peerage and Vale sorts).

ICE1200 RL=a B=b IL=c IS=d IB=e RM=f EM=g BA=h IX=j OX=k

Explanation:

This message relates to the Optimization part of the definition phase (Phase 0).

RL record length (within the Sort);
 B blocking factor used for work areas;
 IL number of physical index blocks per logical index block;
 IS index entry size;
 IB number of indexes/physical index block;
 RM maximum number of strings to be merged in one pass of Phase 2;
 EM maximum number of strings to be merged in Phase 3;
 BA base bin size;
 IX number of input buffers;
 OX number of final output buffers.

ICE121C ET=a CT=b BN=c X=d TO=e SN=f G=g

Explanation:

This message relates to Phase 1.

ET elapsed time taken in centiseconds;
 CT CPU time in centiseconds;
 BN number of blocks handled;
 X number of EXCPs issued;
 TO number of tracks put out;
 SN number of strings produced;
 G number of records in the record storage area.

ICE122R ET=a CT=b BN=c X=d ^G RM=e PN=f BT=g TO=h

Explanation:

This message relates to Phase 2 (Reduction).

ET elapsed time taken in centiseconds;
 CT CPU time in centiseconds;
 BN number of work data set blocks handled;
 X number of EXCPs issued;
 G number of records in the record storage area;
 RM maximum number of strings to be merged in one pass of Phase 2;
 PN highest partition number;
 BT number of tracks handled more than once.
 TO number of tracks put out;

|
| ICE123E ET=a CT=b BN=c X=d G EM =e TO=f BT=g

| Explanation:

| This message relates to Phase 3.

| ET elapsed time taken in centiseconds;
| CT CPU time in centiseconds;
| BN number of work data set blocks handled;
| X number of EXCPs issued;
| G number of records in the record storage area;
| EM maximum number of strings to be merged in
| Phase 3;
| TO number of tracks put out;
| BT number of tracks handled more than once.

| ICE124P ET=a CT=b PE=c RP=d CX=e CO=f C0=g CR=h G=i WB=j

| Explanation:

| This message relates to Phase 2 (Partitioning).

| ET elapsed time taken in centiseconds;
| CT CPU time in centiseconds;
| PE 'peerage': the number of logical strings
| obtained by logically rearranging the tracks
| of physical strings;
| RP number of partitions;
| CX number of exempt blocks;
| CO number of overflow blocks;
| C0 number of blocks in partition 0;
| CR number of blocks to be handled by partition 0;
| G number of records in the record storage area;
| WB number of blocks written back to work storage.

| ICE125O CT=a GP=b SA=e X=d

| Explanation:

| This message relates to work I/O, and is cumulative:
| it appears after each of Phases 1-3, and shows
| cumulative totals each time.

| CT CPU time in centiseconds;
| GP number of work I/O blocks;
| SA number of standalone seeks;
| X number of EXCPs issued.

Messages Produced by Using the DIAG Option

Diagnostic messages are obtained when you specify the DIAG option in the PARM field of the EXEC job control statement. This option is only available for tape techniques, a merge-only application, or when forcing a non-standard disk technique.

The DIAG option impairs program performance, and should be removed as soon as it is no longer needed.

The diagnostic messages are as follows:

ICE900I GENERATED CORE END ADDRxxx	ICE926I IOB TBL ADDR xxxxx
ICE901I INPUT BFR TBL ADDRxxxxx	ICE927I I/P CCW ADDR xxxxx
ICE902I OUTPUT BFR ADDR xxxxx,xxxx	ICE940I GENERATED CORE END ADDR
ICE903I RSA TBL ADDR xxxxx	ICE941I INPUT BFR TBL ADDR xxxxx
ICE904I TREE ADR FROM xxxxx TO xxxxx	ICE942I OUTPUT BFR ADDR xxxxx,xxxxx
ICE905I MOVE RTN ADDR xxxxx	ICE943I MOVE RTN ADDR xxxxx
ICE906I DCB TBL ADDR xxxxx	ICE944I ECB TBL ADDR xxxxx
ICE907I O/P CCW ADDR xxxxx	ICE945I I/P CCW ADDR xxxxx
ICE908I OUTPUT IOB ADDR xxxxx	ICE961I TECHNIQUE xxxxx
ICE909I OPEN LIST ADDR xxxxx	ICE962I NO/SIZE OF BFRS, PH x, x, xxxxx
ICE920I GENERATED CORE END ADDR xxxxx	ICE963I MAX.SYSGEN CORE xxxxx
ICE921I INPUT BFR TBL ADDR xxxxx	ICE964 CALC. CORE PH1=xxxxx
ICE922I OUTPUT BFR ADDR xxxxx,xxxxx	ICE965I MERGE ORDER=xxxxx
ICE923I MOVE RTN ADDR xxxxx	ICE988I ICEyyy LOC. AT xxxxx ¹
ICE924I DCB TBL ADDR	ICE989I CLOCK - xx,xx,xx ²
ICE925I O/P CCW ADDR xxxxx	ICE990I NO OF STRINGS PROD BY PH1 xxxxxxxxx

¹Appears frequently; provides the starting addresses of the program modules.

²Appears at the beginning of each phase (except Phase 0), and at the end of the program.

| Dumps

| There are two types of failure that can cause dumps:

- | • Sort-detected uncorrectable errors which give critical error messages.
- | • Sort program failures that are detected by the operating system.

| NORMAL ABEND DUMPS

| The default `ERETINV|ERETJCL=ABEND|RC16`, which was set when Sort was installed, can be overridden in a standard disk sort by the `DEBUG` control statement or by the `PARM` Field Option `DIAG`. To obtain a normal ABEND dump you must provide a `SYSUDUMP` or `SYSABEND DD` statement.

| An invoked tape sort program, upon detecting an error, will give a return code of 16 unless `DIAG` is specified in the `PARM` Field Option, and a `SYSUDUMP` or `SYSABEND DD` statement is provided.

| THE TRACE TABLE

| In main storage the TRACE table is stored for Blockset in `COMMON` at `COMTRACE` (Register 13 + X'818') and for Peerage and Vale in `ICECOMMA` at `CTRACE` (Register 13 + X'814'). In a formatted dump it is eliminated from `ICECOMMA` dump and shown separately at the end of the `FORMATTED DATA` (see Figure 22). The TRACE table can hold up to 128 trace records, each one byte long. The table is divided into four fields:

FIELD 1	FIELD 2	FIELD 3	FIELD 4
4 bytes	32 bytes	32 bytes	60 bytes

| The table is initialized with zeros.

| How Events are Recorded

| Four types of events are traced

Type	Blockset	Peerage and Vale
Type 1	Record level	Record level
Type 2	Block level	Block level
Type 3	Blockset level	Main loop level
Type 4	Mainly module level	Module level

The object is to keep a long trace of Type 4 events, a shorter trace of Types 3, and 2, and only a short trace of Type 1. For this reason record insertion is carried out as follows:

- A new event is inserted at the end of the field corresponding to the type number; Type 4 goes at the end of field 4, Type 3 at the end of field 3, etc.
- All records to the left of the new one move one byte to the left; the leftmost one (in Field 1) is thus lost.

Format of an Event Record

The Event record is one byte long, and consists of a description code. There are 255 codes (X'00' - X'FF').

| FORCING A SPECIALLY FORMATTED DUMP

| This option is only available for Peerage and Vale.

| The default ERETJCL|ERETINV=ABEND|RC16, which was set when Sort was installed, can be overridden in a standard disk sort by the DEBUG control statement.

| To obtain a specially formatted dump for a sort, the CTRx=value must be specified in the DEBUG statement. This first prints a SNAP dump (corresponding to a normal SYSUDUMP dump), followed by formatted information as shown in Figure 22.

| The formatted part of the dump is derived from the source code, which is written in the PL/S language. As shown in Figure 23 this is not difficult to interpret, even without a knowledge of PL/S. However, if you would like to know more about the language you can find much information, including how to read source code, in the publication Guide to PL/S, GC28-6794.

| Example:

| DEBUG ABEND,CTR2=1

- 1 SYSTEM DUMP
SNAP dump corresponding to a normal SYSUDUMP dump.
- 2 FORMATTED DATA
 - 2.1 Save areas
The standard save areas used by different levels of the program.
 - 2.2 ABEND code
A fullword with the format X'xxsssuuu', where
xx is the standard ABEND code prefix,
sss is the system completion code at program failure (or zeros), and
uuu is the user completion code at uncorrectable error (or zeros).
This code is equal to zero for definition errors, and equal to the message number for other errors (for example, '046' would represent message ICE046A).
 - 2.3 A fullword containing the address of the instruction at which failure occurred.
 - 2.4 Register contents when program failure occurred: 16 fullwords giving the register contents in the order 0-15.
 - 2.5 Contents of ICECOMMA (sort variables) formatted when program failure occurred, with offsets from Register 13, comments, labels, and definitions.
 - 2.6 Trace of important events, in the form

x yyy

where x identifies the part of the program
yyy identifies the segment of code entered.

x can be one of the following codes:

DEF - definition (ICEDEF)
C - creation (ICECRE, ICEVRE, ICEVRN)
P - partitioning (ICEPAR)
R - reduction (ICERED, ICEVED)
E - elimination (ICELIM, ICEVIM, ICELIV, ICEVIP)
A - appendage (for PCI, channel end, or end-of-extent)

The first event listed is the most recent*;
the last is the first that occurred (normally DEF ENTRY).

*If one of the most recent events listed concerns an exit, the probable cause of program failure is a programming error in the exit routine.

Figure 22. Contents of a Specially Formatted Dump

Displacement (in hex) from the start of ICECOMMA	Comment from the source code	The data definition level; a 'level 3' area is always a subset of the preceding 'level 2' area, and so on	Label from the source code	One of the standard PL/S data attributes, eg PTR(31), meaning a fullword pointer	Comment of the area when the dump was taken

	/* WORK AREA */		CWORK108	PTR(8)	

① **Save areas:** The standard save areas are allocated at the beginning of ICECOMMA

② **ABEND CODE:** In the example the program ended with system completion code X'0C1'.

③ **Last instruction:** The address of the failed instruction, in this case X'0CA0F6'.

④ **Register contents:** Shows the register contents when the program failed

⑤ **ICECOMMA:** Remaining contents of ICECOMMA are shown in the same way. For example, field CTEMP1 (also known as CWORK1) contained X'000C936C'. CTEMP124, a subset of the larger area, thus contained X'C936C'.

Figure 23. Interpreting a Formatted Dump

Finding an Object Module in a Storage Dump

As shown in Figure 24, the name of each module appears at the beginning of the module in the storage dump.

Figure 24. The Start of a Module in a Dump

Each module starts with a header consisting of the eight-byte module name followed by the release and PTF number. Some modules have a copyright notice visible after the header.

The module entry point comes after this preliminary material.

With the Blockset technique each load module consists of many object modules. Details are given in Section 3 under 'Phase Structures'. Each object module starts with a header as for the other techniques.

Origin of Program Messages

This subsection shows which modules issue each message. It also tells you how to locate a given message in the source code. This can be useful if, for example, you encounter an error in Phase 0, and can thus not get a dump.

BLOCKSET TECHNIQUE

To find a Blockset message in the code, you should look in the cross reference for labels with the following format:

MSG0xxy

where xx is the message number and y is a letter of the alphabet. The letter A means this is the first use of the message in this module, B means it is the second, and so on. For example, MSG046B would be the second occurrence of message ICE046A.

Message	Module	Message	Module	Message	Module
000	EXIN	046	IPUM	071	COBU
010	INIB		IPVM		COBV
013	INIB		KPUB		E15B
015	COBV		KPUT		E35B
	IPVM		OPUA		OPVT
	15V		KPVT		15V
	35VL	047	IPUT		35VL
017	INIC		IPVT	073	COBV
018	INIB	052	EXIO		IPVM
019	EXIN		OXOV		15V
021	INIB	054	EXIO		35VL
023	INIB		OXOV	074	EXIN
024	INIB	055	EXIO	080	EXIO
025	EXIO		OXOV	081	INIC
	OXOV	056	INIB	083	DYNA
026	EXIO	059	INID	085	EXIO
	OXOV	061	IPUB		OXOV
027	INIC		IPVB	088	EXIN
039	INIO		KPUB	089	EXIN
	IPUT		KPVB	092	EXIN
	IPVT		OPUB	093	EXIN
	KPUT		OPVB	094	INIC
	KPVT	063	INIB	096	MESS
	SUBS		MAN	098	OXOV
042	MAN	067	EXIN	099	IPUM
043	IPUM				IPVB
	INIB				
	IPVT				
	MAN				

ALL OTHER TECHNIQUES

To find a Peerage or Vale message in the code, you should look in the cross reference for labels with the following format:

DIAGxxy

where xx is the message number and y is a letter of the alphabet. The letter A means this is the first use of the message in this module, B means it is the second, and so on. For example, DIAG46B would be the second occurrence of message ICE046A.

Exceptions to the above rule occur in modules ICEDEC and ICEDED, which also use tables for issuing messages. There you should look for labels:

SERRxxy

or

SNERRxx

where xx is the message number, and y is the letter L or P.

²⁰Or VRN

³⁰Or LIV

⁶⁰Or DED

⁹⁰Or RCI

¹⁶8BO if records are spanned

¹⁷RBO if variable non-spanned records, 8BO if spanned

¹⁸Can be issued by any of a large number of modules, including all those which generate control blocks, open, close, and block output.

Look in the dump at the address given in the message.

¹⁹With a conventional technique can be RCI, DED or RCZ

²⁰RCT if a sort terminates unsuccessfully

Cross-Reference Tables

CPI-PPI CROSS-REFERENCE TABLE

The following table contains the names of CPI and PPI fields together with their displacements; the last three letters of the names of modules that reference them; and the manner in which the modules are related to them. A dash is used to separate the module name from the related code. The codes are as follows:

- U The information in the field is u sed by the module.
- M The information in the field is created or m odified by the module. It may also be u sed.
- O Non-specific relationship exists between the module and the field. Either or both of the o ther two codes may, or may not, be applicable.

Register Usage

The general registers used by the sort/merge program for linkage and communication of parameters follow operating system conventions.

Register 1 is used to pass the address of a parameter list to the called routine.

Register 13 contains the address of an area set aside by the sort/merge program, in which a user routine may save the contents of registers.

Register 14 contains the address of the sort/merge program return point.

Register 15 contains the address of the user routine. It is also used by the user routine as a return code register to communicate information to the sort/merge program.

Appendix B: Format Codes (Conventional Techniques)

With a conventional sort or merge each node in the tree contains a code describing the current status of the node.

The structure of a node, and the various format codes as they appear in the second word of that node, are described below.

For fixed-length records the node consists of five words. The first word contains the address of the next-level node with which records associated with the current-level node are compared. In other words, the first-level node points to the second-level node, which points to the third-level node, etc.

The second word contains the format code. This code is a number that is used as a displacement value to index a branch table in the ordering module. The entries in the branch table reflect the sequence (old or new) to which each record at a node belongs. This knowledge precludes needless compares and facilitates the updating of a node after the position of a new record is determined.

The last three words refer to the actual addresses of the three records in the RSA. A binary compare is made to determine which word in the node is to receive which RSA address. If the user specifies ascending sequence, the address of the record with the smallest control field is placed into the first word, the address of the record with the largest control field is placed into the third word, and the address of the record with the control field that collates in the middle is placed into the second word. For descending sequences the order is reversed.

For variable-length records, the node consists of only three words. The first two words contain the next-level node address and format code and are functionally similar to the fixed-length record node described above.

Because of the complexity of address structuring in the variable-length record format, only one record is referred to in the RSA. Hence, only one word is required in the node for this purpose. Functionally, however, the word is similar to that in the fixed-length record node.

Fixed-Length Records

The format codes for fixed-length records are interpreted as follows:

Code	Meaning
0	No record addresses in node.
16	An event has occurred: flushing completed, winner obtained, or new string started. This is a program node, as opposed to a tree node.
32	One address in the node. Record is for new sequence.
48	One address in the node. Record is for same sequence.
64	Two addresses in the node. Both records for new sequence.
80	Two addresses in the node. One record for new sequence, and one record for same sequence.
96	Two addresses in the node. Both records for same sequence.
112	Three addresses in the node. All records for new sequence.
128	Three addresses in the node. Two records for new sequence, one record for same sequence.
144	Three addresses in the node. Two records for same sequence, one record for new sequence.
160	Three addresses in the node. All records for same sequence.

Variable-Length Records

For variable-length records, a slight difference occurs in the format codes because only one record address is entered in each node. The various codes and their meanings are as follows:

Code	Meaning
0	No record address in the node.
16	An event has occurred: flushing completed, winner obtained, or new string started. This is a program node, as opposed to a tree node.
32	Describes the status of the node (see program listing for details).
48	Record address in the node is for a new sequence.
64	Describes the status of the node (see program listing for details).
80	Record address in the node is for the same sequence.

FORMAT CONDITION CODES

The format code determines the point of entry into the instruction sequence. When the instruction sequence is entered, one of four condition codes exists. These condition codes dictate the final disposition of the record and are as follows:

Condition	Interpretation
Flush	Forces records from the tree.
Fill	Continue filling the tree.
Same	Record is of same sequence as previous records.
New	Record begins a new sequence.

Example: Fixed-Length Records

The examples below will aid in interpreting the listings for fixed-length records. The character to the left of the slash represents the record entering the node, and the three characters to the right of the slash represent the records already in the node. Hence, in the program listing, when the comments contain a statement 'This case handles an x/xxx situation', it can be resolved as follows:

Condition	Interpretation
S/SSS	New record is of same sequence as three previous records.
N/SSS	New record begins new sequence; previous three records of same sequence.
-/SSS	Records in tree are of the same sequence, and the program is in flush mode.
N/SSN	Two sequential records, one new sequence in node. New sequence record entering.
-/NNN	Flush mode; all records of new sequence to be flushed.
-/SS-	Flush mode; two records of same sequence to be flushed.
N/S--	One record in the node is of the same sequence; new record begins a new sequence.

Example: Variable-Length Records

For variable-length records, the listings may be interpreted as explained below. The two characters to the left of the slash represent the record entering the node and the two characters to the right of the slash represent the record already in the node.

Condition	Interpretation
S1/S1	New record is of same sequence as previous record.
T1/S1	Record in node is of the same sequence as others in tree. Set status of node to reflect this condition.
T2/S1	Record in node is of the same sequence. New record will change sequence. Set status of node to reflect change.
S2/S2	Record in node is of new sequence. New record is also for new sequence.
T2/S2	Record in node is for new sequence. Set node status to temporary new sequence record.
T2/T1	Set node status at temporary before next record is introduced.

Appendix C. Checkpoint/Restart Facility

If it is included at system generation the sort/merge program may make use of the Checkpoint/Restart Facility of the operating system. The user directs the sort/merge program to use this facility by (1) including the checkpoint parameter (CKPT) in the SORT or MERGE control statement, and (2) providing a SORTCKPT DD statement to define the checkpoint data set; this data set will store the information needed to restart processing.

| Checkpoint procedures are described below for Peerage and Vale, and for
| the conventional sort/merge techniques.

| With Blockset checkpoints are not taken. If a checkpoint has been
| requested the Blockset technique is rejected and another used instead.

Sorting Application (Peerage and Vale)

If checkpoints are requested, the checkpoint macro (CHKPT) is issued and checkpoint records are written on the checkpoint data set as follows:

- ICECKP/ICEVED start of intermediate merge phase
- ICEVIM start of final merge phase
- when the checkpoint track pool is empty.

The relative track addresses of 20-30% (maximum 1364 tracks) of the tracks primarily allocated to the intermediate work files are saved in a track pool. Every time a track of blocks has been read, the relative address is saved in the track pool. When the blocks have to be written the address of an unused track is found in the track pool. A checkpoint is taken when there are no more unused tracks. After the checkpoint has been taken, the saved tracks are available for use again.

Sorting Application (Conventional Techniques)

If checkpoints are requested the following modules link to module ICECHK. This issues checkpoint macro instruction (CHKPT), which causes checkpoint records to be written on the checkpoint data set.

- ICEAPC Start of phase 1 (all techniques)
- ICEAPJ Start of phase 2 (all techniques except crisscross and oscillating)
 Start of each intermediate merge phase pass (balanced direct access technique)
- ICERON During phase 2 (oscillating technique)
- ICEROS During phase 2 (polyphase technique)
- ICEROT During phase 2 (balanced DASD technique)
- ICEAGH Start of phase 3 (all techniques)

The program can be restarted from the checkpoint taken at the start of the sort phase, or from the last checkpoint taken.

Merge-Only Application

If checkpoints are requested they are taken whenever an end-of-volume condition occurs on SORTOUT, unless the user provides his own exit list address for the SORTOUT DCB. Module ICEAPF inserts the address of the checkpoint module ICE8CR in the DCBEXLST field when it generates the SORTOUT DCB (unless this field has been set by a user routine at exit E39). Module ICE8CR is thus entered at the DCB exit list, which contains only the end-of-volume entry. This entry points to the EOVS exit routine in this module, which in turn issues a checkpoint macro instruction (CHKPT), and then returns to the IOCS.

Appendix D. Program Listing Standards and Conventions

To facilitate the identification of modules, work areas, tables, and other aspects of the sort/merge program listing, each technique assigns symbolic names according to a pattern.

Blockset

MODULE NAMES

The format of all module names except ICEMAN and ICEAM1 is ICEmod, where:

ICE is the identification for program modules

mod is a descriptive name for the module (four characters)

INSTRUCTION NAMES

Descriptive names are used. All variables, which are resident in COMMON, begin with the characters 'COM'.

CONSTANT NAMES

Descriptive names are used. 'Constant' is used to mean any item of data defined outside COMMON which is not dynamic (i.e. based on a pointer).

WORK AREA NAMES

Since the program is reenterable, all work areas are variables, and are thus resident in COMMON

Peerage and Vale

MODULE NAMES

The format of all module names is ICEmod, as described under 'Blockset' above. The descriptive portion (mod) is 3 characters long.

INSTRUCTION NAMES

Descriptive names are used. All variables, which are resident in ICECOMMA, begin with the character 'C'.

CONSTANT NAMES

Descriptive names are used. 'Constant' is used to mean any item of data defined outside ICECOMMA which is not dynamic (i.e. based on a pointer).

WORK AREA NAMES

Since the program is reenterable, all work areas are variables, and are thus resident in ICECOMMA.

Conventional Techniques

MODULE NAMES

| The format of module names is ICEtmm, where:

ICE is the identification for program modules.

t, in general, is either an 'A' for an Assignment or an 'R' for a Running type module; however, for some assignment modules associated with the crisscross technique, t is '9', and for some running modules associated with the crisscross technique, t is '8'.

mm is the unique portion of the module name.

INSTRUCTION NAMES

The format of all internal type instruction names is mmmnnnnno or mmmnnnnno where:

mm or mmm represents the last two or three characters of the module name.

nnnnn or nnnn is a unique designation assigned by the programmer and may be from one to five characters.

o is an 'X' if the label is externally used; otherwise it can be used as another n.

Appendix E: SMF Record DSECT (ICESMF)

This area is allocated and filled in by ICEEXIO, ICEOXOV, or ICEMOS depending on the sort technique used. The record is passed to sort's SVC routine, ICEFIXM (OS/VS2) or ICEFIX (OS/VS1). The SVC routine uses the passed record and issues the SMF macro to write the SMF record out to the SMF data set, upon successful completion of the sort/merge application.

DISP	NAME			DESCRIPTION
0000	ICESMF	DSECT		
0000	ICERDW	DS	XL4	RECORD DESCRIPTOR WORD
