CHAPTER 1

About

VyOS is an open source network operating system based on Debian GNU/Linux.

VyOS provides a free routing platform that competes directly with other commercially available solutions from well known network providers. Because VyOS runs on standard amd64, i586 and ARM systems, it is able to be used as a router and firewall platform for cloud deployments.

We use multiple live versions of our manual, hosted thankfully by <https://readthedocs.org>. We will provide one version of the manual for every VyOS major version starting with VyOS 1.2 which will receive Long-term support (LTS).

The manual version is selected/specified by it's Git branch name. You can switch between versions of the documentation by selecting the appropriate branch on the bottom left corner.

VyOS CLI syntax may change between major (and sometimes minor) versions. Please always refer to the documentation matching your current, running installation. If a change in the CLI is required, VyOS will ship a so called migration script which will take care of adjusting the syntax. No action needs to be taken by you.

VyOS is a Linux-based network operating system that provides software-based network routing, firewall, and VPN functionality.

The VyOS project was started in late 2013 as a community fork of the [GPL](#) portions of Vyatta Core 6.6R1 with the goal of maintaining a free and open source network operating system in response to the decision to discontinue the community edition of Vyatta. Here everyone loves learning, older managers and new users.

VyOS is primarily based on [Debian GNU/Linux](#) and the [Quagga](#) routing engine. Its configuration syntax and *Command Line Interface* are loosely derived from Juniper JUNOS as modelled by the [XORP project](#), which was the original routing engine for Vyatta.

In the 4.0 release of Vyatta, the routing engine was changed to Quagga. As of VyOS version 1.2, VyOS now uses [FRRouting](#) as the routing engine.

How is VyOS different from any other router distributions and platform?

- It's more than just a firewall and VPN, VyOS includes extended routing capabilities like OSPFv2, OSPFv3, BGP, VRRP, and extensive route policy mapping and filtering
- Unified command line interface in the style of hardware routers.
- Scriptable CLI
- Stateful configuration system: prepare changes and commit at once or discard, view previous revisions or roll-back to them, archive revisions to remote server and execute hooks at commit time
- Image-based upgrade: keep multiple versions on the same system and revert to previous image if a problem arises
- Multiple VPN capabilities: OpenVPN, IPsec, Wireguard, DPMVPN, IKEv2 and more
- DHCP, TFTP, mDNS repeater, broadcast relay and DNS forwarding support
- Both IPv4 and IPv6 support
- Runs on physical and virtual platforms alike: small x86 boards, big servers, KVM, Xen, VMware, Hyper-V, and more
- Completely free and open source, with documented internal APIs and build procedures

- Community driven. Patches are welcome and all code, bugs, and nightly builds are publicly accessible

3.1 1.4 Sagitta

3.1.1 2021-08-01

- [T3707](#) (bug): Ping incorrect ip host checks

3.1.2 2021-07-31

- [T3711](#) (default): service router-advert interface <name> dnssl option has no effects
- [T3716](#) (feature): Linux kernel parameters ignore_routes_with_link_down- ignore disconnected routing connections

3.1.3 2021-07-30

- [T1176](#) (default): FRR - BGP replicating routes
- [T1210](#) (feature): About IKEv2 IPSec VPN remote access

3.1.4 2021-07-23

- [T3699](#) (bug): login: verify selected “system login user” name is not already used by the base system.
- [T3698](#) (default): Support bridge monitoring

3.1.5 2021-07-13

- [T3679](#) (default): Point the unexpected exception message link to the new rolling release location

3.1.6 2021-07-11

- T3665 (bug): Missing VRF support for VxLAN but already documented

3.1.7 2021-07-10

- T3636 (feature): SSTP / L2TP ipv6 support broken

3.1.8 2021-07-09

- T3667 (bug): brctl is damaged

3.1.9 2021-07-06

- T3660 (feature): Conntrack-Sync configuration command to specify destination udp port for peer

3.1.10 2021-07-03

- T57 (enhancement): Make it possible to disable the entire IPsec peer

3.1.11 2021-07-01

- T3658 (feature): Add support for dhcpdv6 fixed-prefix6
- T2035 (bug): Executing vyos-smoketest multiple times makes ssh test fail on execution

3.1.12 2021-06-29

- T3593 (bug): PPPoE server called-sid format does not work
- T3657 (default): BGP neighbors ipv6 not able to establish with IPv6 link-local addresses
- T1441 (feature): Add support for IPSec XFRM interfaces

3.1.13 2021-06-27

- T3653 (default): Cloudinit subnet error if a cidr (/24) is used instead of a subnet mask (255.255.255.0)

3.1.14 2021-06-25

- T3641 (feature): Upgrade base system from Debian Buster -> Debian Bullseye
- T3649 (feature): Add bonding additional hash-policy

3.1.15 2021-06-23

- T3647 (feature): Bullseye: gcc defaults to passing `-as-needed` to linker
- T3644 (default): Replace GCC with a simpler preprocessor for including nested XML snippets in XML documents
- T3356 (feature): Script for remote file transfers

3.1.16 2021-06-22

- T3629 (bug): IPoE server shifting address in the range
- T3645 (feature): Bullseye: ethtool changed output for ring-buffer information
- T3582 (default): ‘delete log file’ does not work

3.1.17 2021-06-21

- T3563 (default): commit-archive breaks with IPv6 source addresses

3.1.18 2021-06-20

- T3637 (bug): vrf: bind-to-all didn’t work properly
- T3639 (default): GCC preprocessor clobbers C comments

3.1.19 2021-06-19

- T3633 (feature): Add LRO offload for interface ethernet
- T3632 (bug): policy: route-map: unable to configure route-target / site-of-origin

3.1.20 2021-06-18

- T3634 (feature): Add op command option for ping for do not fragment bit to be set
- T3599 (default): Migrate NHRP to XML/Python

3.1.21 2021-06-17

- T3624 (feature): BGP: add support for extended community bandwidth definition

3.1.22 2021-06-16

- T3623 (default): Fix for dummy interface option in the operational command “clear interfaces dummy”
- T3630 (feature): op-mode: add “show version kernel” command

3.1.23 2021-06-13

- T3620 (feature): Rename WWAN interface from wirelessmodem to wwan to use QMI interface
- T2173 (feature): Add the ability to use VRF on VTI interfaces
- T3622 (feature): WWAN: add support for APN authentication
- T3606 (bug): SNMP unknown notification OID
- T3621 (bug): PPPoE interface does not validate if password is supplied when username is set

3.1.24 2021-06-12

- T3611 (bug): WWAN interface (MC7710) no longer works on Kernel 5.10
- T1534 (bug): IPSec w/ IKEv2 Invalid local-address “any”
- T3616 (bug): Update to FastAPI causes regression in vyos-http-api-server

3.1.25 2021-06-11

- T3614 (bug): Container network name with hyphen fail

3.1.26 2021-06-10

- T3250 (bug): PPPoE server: wrong local usernames
- T3138 (bug): ddclient improperly updated when apply rfc2136 config
- T2620 (feature): Add ipsec peer-name to log to simplifies grepping and troubleshooting
- T2645 (default): Editing route-map Action Requires New Rule

3.1.27 2021-06-08

- T3605 (default): Allow to set prefer-global for ipv6-next-hop
- T3607 (feature): [route-map] set ipv6 next-hop prefer-global
- T3289 (bug): No description for node “service” conf-mode

3.1.28 2021-06-07

- T3461 (bug): OpenConnect Server redundancy check
- T3455 (bug): system users can not be added in “edit”
- T3588 (default): IPSec: migrate no longer available options from CLI which are now hardcoded/enabled in strongSwan

3.1.29 2021-06-06

- T842 (feature): Adopt VyOS CLI to latest StrongSwan options and deprecated Keywords

3.1.30 2021-06-04

- T3595 (default): Cannot create new VTI interface
- T3592 (feature): Set default TTL 64 for tunnels

3.1.31 2021-06-03

- T3384 (feature): Support UDP bandwidth testing

3.1.32 2021-06-02

- T3233 (bug): Interface redirect to dum0

3.1.33 2021-06-01

- T3585 (default): Fix NHRP module for updated interfaces tunnel syntax
- T3594 (bug): Disable by default service strongswan-starter

3.1.34 2021-05-30

- T3524 (default): Please implement bgp graceful-shutdown
- T3518 (bug): Warning messages when using SCP commit-archive
- T3093 (default): Add xml for vpn ipsec
- T1866 (bug): Commit archive over SFTP doesn't work with non-standard ports
- T3590 (feature): bgp: add option for limiting maximum number of prefixes to be sent to a peer
- T3589 (feature): op-mode: support clearing out logfiles from CLI
- T2641 (feature): Rewrite vpn ipsec OP commands in new style XML syntax
- T3351 (feature): Installer checking MD5 checksums on the ISO image

3.1.35 2021-05-29

- T1944 (bug): FRR: Invalid route in BGP causes update storm, memory leak, and failure of Zebra.
- T1888 (feature): Update to StrongSwan 5.9.1
- T1995 (bug): "show vpn ike sa" command always show child-sas as down

3.1.36 2021-05-27

- T3561 (feature): router-advert: support advertising specific routes
- T2669 (bug): DHCP-server overlapping ranges.

3.1.37 2021-05-26

- T3540 (bug): Keepalived memory utilisation issue when constantly getting its state in JSON format

3.1.38 2021-05-25

- T3569 (bug): Firewall wrong completion help values

3.1.39 2021-05-24

- T3575 (bug): pseudo-ethernet: must check source-interface MTU
- T3571 (bug): Broken Show Tab Complete
- T3555 (bug): GRE TAP tunnel does not silent fragment packets / kernel fix available
- T3576 (bug): ISIS does not support IPV6

3.1.40 2021-05-23

- T3570 (default): Prevent setting of a larger MTU on child interfaces
- T3573 (bug): as-path-prepend Description Invalid
- T3572 (feature): Basic Drive Diagnostic Tools

3.1.41 2021-05-22

- T3564 (default): Multiple BGP Confederation Peers Not Allowed

3.1.42 2021-05-21

- T3551 (bug): QoS control failure of VLAN sub interface

3.1.43 2021-05-20

- T3554 (feature): Add area-type stub for ospfv3
- T3565 (feature): sysctl: rewrite in XML and Python and drop from vyatta-cfg-system

3.1.44 2021-05-19

- T3562 (feature): Update Accel-PPP to a newer revision
- T3559 (feature): Add restart op-command for OpenConnect Server

3.1.45 2021-05-18

- T3525 (default): VMWare resume script syntax errors

3.1.46 2021-05-17

- T3557 (bug): ddclient: FileNotFoundError in op-mode

3.1.47 2021-05-15

- T3549 (bug): DHCPv6 “service dhcpv6-server global-parameters name-server” is not correctly exported to dhcpdv6.conf when multiple name-server entries are present
- T3532 (bug): Not possible to change ethertype after interface creation
- T3550 (bug): Router-advert completion typo
- T3547 (feature): conntrackd: remove deprecated config options
- T3535 (feature): Rewrite vyatta-conntrack-sync in new XML and Python flavor

3.1.48 2021-05-14

- T3346 (bug): nat 4-to-5 migration script fails when a ‘source’ or ‘destination’ node exists but there are no rules
- T3248 (default): Deal with VRRP mode-force command that exists in 1.2 but not in 1.3
- T2809 (bug): An issue with config migration (system ntp server)
- T3426 (default): add support for script arguments to vyos-configd

3.1.49 2021-05-13

- T3539 (bug): Typo in RPKI interface definition
- T439 (feature): local PBR support
- T3544 (feature): DHCP server should validate configuration before applying it
- T3543 (feature): Support for setting lacp_rate on LACP bonded interfaces

3.1.50 2021-05-12

- T3302 (default): Make vyos-configd relay stdout from scripts to the user’s console
- T3542 (bug): udev net.rules not installed in image since may 2nd

3.1.51 2021-05-10

- T3374 (bug): IPv6 GRE Tunnel issues

3.1.52 2021-05-09

- T3530 (bug): BGP peer-group can’t contain a hyphen
- T3531 (bug): policy: prefix-list and route-map names do not allow underscores in names (FRR does)

3.1.53 2021-05-07

- T3333 (bug): “show vpn ipsec sa” reports ESP tunnels to be up when they are not.

3.1.54 2021-05-06

- T3523 (bug): VRF BGP daemon route-map command missing
- T3519 (bug): Cannot add / assign L2TPv3 to vrf

3.1.55 2021-05-05

- T3520 (bug): Cannot add tunnel interface to isis within vrf
- T3335 (bug): Some OSPFv3 show commands do not work

3.1.56 2021-05-04

- T3504 (feature): BGP Per Peer Graceful Restart

3.1.57 2021-05-02

- T3511 (bug): Update libnss-mapuser and libpam-radius packages from CUMULUS Linux
- T3510 (bug): RADIUS username is not shown on CLI

3.1.58 2021-05-01

- T3379 (feature): Add global-parameters name-server for dhcpv6-server
- T3491 (default): Change Kernel HZ to 1000

3.1.59 2021-04-29

- T3503 (bug): “route-reflector-client” fails when “remote-as” is “internal”
- T3502 (bug): “system ip multipath layer4-hashing” doesn’t work

3.1.60 2021-04-28

- T3473 (bug): IPSec op-mode show sa error

3.1.61 2021-04-27

- T3458 (default): vyos docs missing gretap from tunnel section
- T2946 (bug): call to commandd ‘stty_size’ cause show interfaces API to fail.

3.1.62 2021-04-26

- T3487 (bug): Specifying an invalid “interface address” like dhcp leads to commit error

3.1.63 2021-04-25

- T3490 (bug): priority inversion on PBR “policy route” create, breaks default route from dhcp (live iso)
- T3468 (bug): Tunnel interfaces aren’t suggested as being available for bridging (regression)
- T3497 (bug): Prefix list with rule containing only action is not detected as error during parse
- T3492 (bug): BGP Configuration Migration failed (badly!) from rolling 202102240218 to rolling 202104221210
- T1802 (feature): Wireguard QR code in cli for mobile devices

3.1.64 2021-04-24

- T3472 (bug): commit-confirm script not found
- T3439 (bug): Commit-archive location not working for scp

3.1.65 2021-04-23

- T3395 (bug): WAN load-balancing fails with nexthop dhcp
- T3290 (bug): Disabling GRE conntrack module fails

3.1.66 2021-04-20

- T3488 (bug): Specifying an invalid “interface address” like dhcp leads to commit error

3.1.67 2021-04-18

- T3481 (default): Exclude tag node values from key mangling
- T3475 (bug): XML dictionary cache unable to process syntaxVersion elements

3.1.68 2021-04-17

- T3470 (bug): as-override isn’t applied to frr

3.1.69 2021-04-15

- T3386 (bug): PPPoE-server don’t start with local authentication
- T3190 (feature): Unable to subtract value from local-preference in route-map

3.1.70 2021-04-14

- T3398 (bug): Can't commit
- T3055 (bug): op-mode incorrect naming fo ipsec policy-based tunnels

3.1.71 2021-04-13

- T3436 (feature): Refactoring ospf op-mode for support vrf
- T3434 (feature): Refactoring bgp op-mode for support vrf

3.1.72 2021-04-12

- T3454 (enhancement): dhclient reject option
- T3328 (bug): Bgp not possible to delete bgp route-map

3.1.73 2021-04-11

- T3435 (bug): NAT rules show corruption

3.1.74 2021-04-10

- T3460 (bug): bgp, Configuration FRR failed while committing code

3.1.75 2021-04-09

- T3464 (bug): OSPF: route-map names containing a hypen are not “found”

3.1.76 2021-04-08

- T3462 (default): show ipv6 bgp – missing
- T3456 (bug): firewall: rules that should be deleted seem to be still in use
- T3463 (bug): Prevent IPv4 Route exchange with IPv6 neighbors

3.1.77 2021-04-05

- T3438 (bug): VRF: removing vif which belongs to a vrf, will delete the entire vrf from the operating system
- T3418 (bug): BGP: system wide known interface can not be used as neighbor

3.1.78 2021-04-04

- T3457 (feature): Output the “monitor log” command in a colorful way

3.1.79 2021-03-31

- T3445 (bug): vyos-1x build include not all nodes

3.1.80 2021-03-30

- T3448 (bug): Loading vyos on a system without xdp installed fails

3.1.81 2021-03-29

- T3415 (feature): bridge: add support for isolated interfaces (private-vlan)
- T1711 (feature): BGP - migrate from tagNode to node (remove ASN from tagNode)

3.1.82 2021-03-28

- T3440 (bug): HTTP API: give uvicorn time to initialize before restarting Nginx proxy

3.1.83 2021-03-27

- T3423 (bug): Cannot create ipv4 static route for default gateway in vrf

3.1.84 2021-03-26

- T3412 (default): HTTP API: move to FastAPI as web framework
- T2397 (feature): HTTP API: export OpenAPI definition

3.1.85 2021-03-24

- T3419 (bug): show interfaces | strip-private fails
- T3307 (default): address prefix destination NAT fails to render nftables rules / commit

3.1.86 2021-03-22

- T3402 (feature): Add VyOS programming library for operational level commands
- T3284 (bug): merge/load fail silently if unable to resolve host

3.1.87 2021-03-21

- T3417 (default): ISIS: provide per VRF instance support
- T3416 (bug): NTP: when running inside a VRF op-mode commands do not work

3.1.88 2021-03-20

- T3392 (bug): vrrp over dhcp default route bug (unexpected vrf)
- T3373 (feature): Upgrade to SaltStack version 3002.5
- T3329 (default): “system conntrack ignore” rules can no longer be created due to an iptables syntax change
- T3300 (feature): Add DHCP default route distance
- T3306 (feature): Extend set route-map aggregator as to 4 Bytes

3.1.89 2021-03-18

- T3411 (default): Extend the redirect_stdout context manager in vyos-config to redirect stdout from subprocesses
- T3271 (bug): qemu-kvm grub issue

3.1.90 2021-03-17

- T3413 (bug): Configuring invalid IPv6 EUI64 address results in “OSError: illegal IP address string passed to inet_pton”

3.1.91 2021-03-15

- T3354 (default): Convert strip-private script from Perl to Python

3.1.92 2021-03-14

- T3345 (default): BGP: add per VRF instance support
- T3344 (default): Per VRF dynamic routing support
- T3325 (bug): Bgp listen-range wrong commit message
- T1513 (default): Move OSPF and RIP interface configuration under protocols

3.1.93 2021-03-13

- T3406 (bug): tunnel: interface no longer supports specifying encaps limit none - or migrator is missing
- T3407 (bug): console-server: do not allow to spawn a console-server session on serial port used by “system console”

3.1.94 2021-03-11

- T3305 (bug): Ingress qdisc does not work anymore in 1.3-rolling-202101 snapshot
- T2927 (bug): isc-dhcpd release and expiry events never execute

3.1.95 2021-03-09

- T3389 (default): gretap tunnel type missing from vyos documentation after renamed from gre-bridge
- T3382 (bug): Error creating Console Server

3.1.96 2021-03-08

- T3387 (bug): Command “Monitor vpn ipsec” is not working

3.1.97 2021-03-07

- T3388 (bug): show interfaces doesn’t display pppoeX
- T3211 (feature): ability to redistribute ISIS into other routing protocols

3.1.98 2021-03-04

- T3377 (bug): show interfaces throws error

3.1.99 2021-03-02

- T3375 (bug): Interface becomes up at boot even when disabled

3.1.100 2021-02-28

- T3370 (bug): dhcp: Invalid domain name “private”
- T3369 (feature): VXLAN: add IPv6 underlay support
- T3363 (bug): VyOS-Build interactive prompt when using Podman
- T3320 (bug): Bgp neighbor peer-group without peer-group fail

3.1.101 2021-02-27

- T3365 (bug): Bgp neighbor interface ordering for remote-as
- T3225 (bug): Adding a BGP neighbor with an address on a local interface throws a vyos.frr.CommitError: Configuration FRR failed while committing code: ‘’
- T3368 (feature): macsec: add support for gcm-aes-256 cipher
- T3173 (feature): Need ‘nopmtudisc’ option for tunnel interface

3.1.102 2021-02-26

- T3324 (bug): Bgp space in the password
- T3357 (default): HTTP-API redirect from http correct https port
- T3323 (bug): Bgp ttl-security and ebgp-multihop fail

3.1.103 2021-02-24

- T3303 (feature): Change welcome message on boot

3.1.104 2021-02-22

- T3322 (bug): Bgp neighbor timers not applied to FRR config
- T3327 (bug): OSPFv3: Cannot add dummy interface

3.1.105 2021-02-21

- T3331 (bug): Bgp unsuppress-map should be as “value leafNode”
- T3330 (bug): Bgp capability orf prefix-list fail
- T3163 (feature): ethernet ring-buffer can be set with an invalid value

3.1.106 2021-02-19

- T3326 (bug): OSPFv3: Cannot add L2TPv3 interface
- T3332 (bug): BGP unnumbered - UnboundLocalError: local variable ‘peer_group’ referenced before assignment

3.1.107 2021-02-18

- T3259 (default): many dnat rules makes the vyos http api crash, even showConfig op timeouts

3.1.108 2021-02-17

- T3312 (feature): SolarFlare NICs support

3.1.109 2021-02-16

- T3313 (bug): ospfv3 interface missing options
- T3318 (feature): Update Linux Kernel to v5.4.135 / 5.10.53

3.1.110 2021-02-15

- T3311 (bug): BGP Error: Remote AS must be set for neighbor or peer-group

3.1.111 2021-02-14

- T2848 (feature): bgp-add-path configuration options
- T1875 (feature): Add the ability to use network address as BGP neighbor (bgp listen range)

3.1.112 2021-02-12

- T3301 (bug): Wrong format and valueHelp for policy as-path-list regex

3.1.113 2021-02-11

- T3281 (default): Rewrite protocol RIPng [conf-mode] to new XML/Python style
- T3282 (default): Add XML for [conf-mode] RIPng
- T3279 (default): Rewrite protocol STATIC [op-mode] to new XML/Python style
- T3297 (bug): Optimize irrelevant error stack hints

3.1.114 2021-02-08

- T3295 (feature): Update Linux Kernel to v5.4.96 / 5.10.14

3.1.115 2021-02-05

- T3030 (feature): Support ERSPAN Tunnel Protocol

3.1.116 2021-02-04

- T3283 (feature): Support for IPv4 neigh tables
- T3280 (default): Add XML for [conf-mode] STATIC

3.1.117 2021-02-03

- T3278 (feature): Add XML for “protocols vrf” [conf-mode]
- T3239 (default): XML: override ‘defaultValue’ for mtu of certain interfaces; remove workarounds
- T2910 (feature): XML: generator should support override of variables

3.1.118 2021-02-02

- T3018 (bug): Unclear behaviour when configuring vif and vif-s interfaces
- T3255 (default): Rewrite protocol RPKI to new XML/Python style
- T3263 (feature): OSPF Hello subsecond timer

3.1.119 2021-01-31

- T3276 (feature): Update Linux Kernel to v5.4.94 / 5.10.12

3.1.120 2021-01-30

- T3240 (feature): Support per-interface DHCPv6 DUIDs
- T3273 (default): PPPoE static default-routes deleted on interface down when not added by interface up

3.1.121 2021-01-29

- T3261 (bug): Does not possible to disable pppoe client interface.
- T3272 (default): OSPF: interface config is not removed

3.1.122 2021-01-27

- T3257 (feature): tcpdump supporting complete protocol
- T3244 (default): Rewrite protocol OSPFv3 to new XML/Python style

3.1.123 2021-01-26

- T3251 (bug): PPPoE client trying to authorize with the wrong username
- T3256 (default): Add XML for protocol RPKI [conf-mode]

3.1.124 2021-01-25

- T3249 (feature): Support operation mode forwarding table output

3.1.125 2021-01-24

- T3227 (bug): Latest releases don't work with RPKI (crash)
- T3230 (bug): RPKI can't be deleted
- T3221 (bug): FRR config
- T3245 (default): Add XML for protocol ospfv3 [conf-mode]

3.1.126 2021-01-23

- T3236 (default): Add XML for [conf-mode] OSPF

3.1.127 2021-01-17

- T3222 (bug): BGP dampening description
- T3226 (bug): Repair bridge smoke test damage

3.1.128 2021-01-16

- T3215 (bug): show ipv6 route Broken on 1.4 Rolling
- T3157 (bug): salt-minion fails to start due to permission error accessing /root/.salt/minion.log
- T3137 (feature): Let VLAN aware bridge approach the behavior of professional equipment

3.1.129 2021-01-15

- T3210 (feature): ISIS three-way-handshake
- T3184 (feature): Add correct descriptions for BGP neighbors

3.1.130 2021-01-14

- T3213 (bug): show interface command python error

3.1.131 2021-01-12

- T3205 (bug): Does not possible to configure tunnel mode gre-bridge

3.1.132 2020-12-20

- T3132 (feature): Enable egress flow accounting

3.1.133 2020-07-20

- T2717 (default): Wrong DHCP server pool size in statistics

3.2 1.3 Equuleus

3.2.1 2021-08-01

- T3707 (bug): Ping incorrect ip host checks

3.2.2 2021-07-31

- T3711 (default): service router-advert interface <name> dnssl option has no effects
- T3716 (feature): Linux kernel parameters ignore_routes_with_link_down- ignore disconnected routing connections
- T1626 (bug): BGP exchanges prefixes without specified address-family

3.2.3 2021-07-30

- T1176 (default): FRR - BGP replicating routes
- T1123 (bug): Inconsistency in community-list naming validation

3.2.4 2021-07-29

- T3498 (default): Prevent automated publication of releases that weren't yet hand-tested
- T2931 (bug): Unicode decode error causes vyos.configd service to restart
- T2727 (bug): Add a dotted decimal value validator
- T2328 (default): dhcpv6 server not starting (disable check reversed?)
- T1758 (default): Switch vyos.config to libvyosconfig
- T954 (bug): Using the 10.255.255.0/24 subnet on other interfaces breaks L2TP/IPSec
- T1187 (bug): Command show log vpn display wrong information

3.2.5 2021-07-23

- T3699 (bug): login: verify selected "system login user" name is not already used by the base system.

3.2.6 2021-07-21

- T3689 (bug): static ipv6 route doesn't deleted in some cases
- T3685 (feature): IPv6 PBR doesn't allow setting of an egress interface

3.2.7 2021-07-20

- T3691 (bug): GRETAP: key is not applied when interface is created

3.2.8 2021-07-13

- T3679 (default): Point the unexpected exception message link to the new rolling release location

3.2.9 2021-07-11

- T3665 (bug): Missing VRF support for VxLAN but already documented

3.2.10 2021-07-06

- T3660 (feature): Conntrack-Sync configuration command to specify destination udp port for peer

3.2.11 2021-07-01

- T3658 (feature): Add support for dhcpdv6 fixed-prefix6

3.2.12 2021-06-29

- T3593 (bug): PPPoE server called-sid format does not work

3.2.13 2021-06-27

- T3653 (default): Cloudinit subnet error if a cidr (/24) is used instead of a subnet mask (255.255.255.0)

3.2.14 2021-06-25

- T3650 (bug): OpenVPN: Upgrade package to 2.5.1 before releasing VyOS 1.3.0
- T3649 (feature): Add bonding additional hash-policy

3.2.15 2021-06-24

- T2722 (bug): get_config_dict() and key_mangling=('-', '_') will alter CLI data for tagNodes

3.2.16 2021-06-22

- T3629 (bug): IPoE server shifting address in the range
- T3582 (default): 'delete log file' does not work

3.2.17 2021-06-20

- T3637 (bug): vrf: bind-to-all didn't work properly

3.2.18 2021-06-19

- T3633 (feature): Add LRO offload for interface ethernet
- T3632 (bug): policy: route-map: unable to configure route-target / site-of-origin

3.2.19 2021-06-18

- T3634 (feature): Add op command option for ping for do not fragment bit to be set

3.2.20 2021-06-17

- T3631 (feature): route-map: migrate "set extcommunity-rt" and "set extcommunity-soo" to "set extcommunity rtlsso" to match FRR syntax

3.2.21 2021-06-16

- T3623 (default): Fix for dummy interface option in the operational command “clear interfaces dummy”
- T2425 (feature): Rewrite all policy zebra filters to XML/Python style
- T3630 (feature): op-mode: add “show version kernel” command

3.2.22 2021-06-13

- T3620 (feature): Rename WWAN interface from wirelessmodem to wwan to use QMI interface
- T3622 (feature): WWAN: add support for APN authentication
- T3621 (bug): PPPoE interface does not validate if password is supplied when username is set

3.2.23 2021-06-12

- T3609 (bug): BGP Peer Group Changes Slow

3.2.24 2021-06-10

- T3250 (bug): PPPoE server: wrong local usernames
- T3138 (bug): ddclient improperly updated when apply rfc2136 config
- T2620 (feature): Add ipsec peer-name to log to simplifies grepping and troubleshooting
- T2645 (default): Editing route-map Action Requires New Rule

3.2.25 2021-06-09

- T3602 (bug): Renaming BGP Peer Groups Leaves Router Broken
- T2916 (bug): A state of VTI interface in a configuration does not being processing properly
- T2855 (default): disabled vti interfaces still working

3.2.26 2021-06-08

- T3605 (default): Allow to set prefer-global for ipv6-next-hop
- T3607 (feature): [route-map] set ipv6 next-hop prefer-global
- T3289 (bug): No description for node “service” conf-mode

3.2.27 2021-06-07

- T3581 (bug): Incomplete command *show ipv6 ospfv3 linkstate*
- T3516 (bug): FRR 7.5 adds a second route when you attempt to change a static route distance instead of overwriting the old route
- T3461 (bug): OpenConnect Server redundancy check
- T3455 (bug): system users can not be added in “edit”

3.2.28 2021-06-04

- T3592 (feature): Set default TTL 64 for tunnels

3.2.29 2021-06-01

- T406 (bug): VPN configuration error: IPv6 over IPv4 IPsec is not supported when using IPv6 ONLY tunnel.

3.2.30 2021-05-30

- T3524 (default): Please implement bgp graceful-shutdown
- T1866 (bug): Commit archive over SFTP doesn't work with non-standard ports
- T3589 (feature): op-mode: support clearing out logfiles from CLI
- T3508 (bug): Check if there's enough drive space for an upgrade before downloading an image
- T1506 (enhancement): commit-archive scp/sftp public key authentication

3.2.31 2021-05-29

- T3135 (bug): BFD configurations fail to be applied
- T3103 (default): Rewrite parts of vyosfrr.py for readability, logging and to fix multiline regex "bugs"
- T2739 (default): vyos-utils is not compiled with a Jenkins pipeline.
- T2451 (bug): Cannot use !tcp or !tcp_udp while adding firewall rule
- T2436 (default): equuleus: Testing: vyos-1x: syntax checking python scripts in PR
- T2184 (bug): OpenVPN op_mode tools broken
- T1944 (bug): FRR: Invalid route in BGP causes update storm, memory leak, and failure of Zebra.
- T1995 (bug): "show vpn ike sa" command always show child-sas as down

3.2.32 2021-05-28

- T1579 (feature): Rewrite all interface types in new XML/Python style

3.2.33 2021-05-27

- T2629 (bug): VXLAN interfaces don't actually allow you to configure most settings
- T2617 (feature): Rewrite vyatta-op-quagga "show" to XML
- T2512 (feature): vyatta-op-quagga [show ip] to XML format
- T1905 (default): Update to Keepalived 2.0.19
- T2669 (bug): DHCP-server overlapping ranges.

3.2.34 2021-05-26

- T3558 (default): autocomplete options for dhcp-interface is not showing for the static route command
- T3540 (bug): Keepalived memory utilisation issue when constantly getting its state in JSON format
- T2807 (feature): IPv6 Link-Local Address - Automatically generation/configuration on GRE Interfaces

3.2.35 2021-05-25

- T3569 (bug): Firewall wrong completion help values

3.2.36 2021-05-24

- T3575 (bug): pseudo-ethernet: must check source-interface MTU
- T3571 (bug): Broken Show Tab Complete
- T3576 (bug): ISIS does not support IPV6

3.2.37 2021-05-23

- T3570 (default): Prevent setting of a larger MTU on child interfaces
- T3572 (feature): Basic Drive Diagnostic Tools

3.2.38 2021-05-20

- T3554 (feature): Add area-type stub for ospfv3

3.2.39 2021-05-19

- T3562 (feature): Update Accel-PPP to a newer revision
- T3559 (feature): Add restart op-command for OpenConnect Server

3.2.40 2021-05-18

- T3525 (default): VMWare resume script syntax errors
- T2462 (default): LLDP op-mode exception: IndexError: list index out of range

3.2.41 2021-05-17

- T3557 (bug): ddclient: FileNotFoundError in op-mode

3.2.42 2021-05-15

- T3549 (bug): DHCPv6 “service dhcpv6-server global-parameters name-server” is not correctly exported to dhcpdv6.conf when multiple name-server entries are present
- T3532 (bug): Not possible to change ethertype after interface creation
- T3550 (bug): Router-advert completion typo
- T3547 (feature): conntrackd: remove deprecated config options
- T3535 (feature): Rewrite vyatta-conntrack-sync in new XML and Python flavor
- T2049 (feature): Update strongSwan cipher suites list for IPSec settings

3.2.43 2021-05-14

- T3346 (bug): nat 4-to-5 migration script fails when a ‘source’ or ‘destination’ node exists but there are no rules
- T3248 (default): Deal with VRRP mode-force command that exists in 1.2 but not in 1.3
- T2809 (bug): An issue with config migration (system ntp server)
- T3426 (default): add support for script arguments to vyos-configd

3.2.44 2021-05-13

- T3538 (default): Can’t configure wireless as access-point
- T3544 (feature): DHCP server should validate configuration before applying it
- T3543 (feature): Support for setting lacp_rate on LACP bonded interfaces

3.2.45 2021-05-12

- T3302 (default): Make vyos-configd relay stdout from scripts to the user’s console

3.2.46 2021-05-11

- T3526 (bug): Smoketest policy fail in CI

3.2.47 2021-05-10

- T3528 (bug): Frr 7.5.1 uses ‘seq’ for community-lists

3.2.48 2021-05-09

- T3531 (bug): policy: prefix-list and route-map names do not allow underscores in names (FRR does)

3.2.49 2021-05-08

- T3517 (bug): FRR 7.5 bfd behavior for 1.3

3.2.50 2021-05-07

- T3333 (bug): “show vpn ipsec sa” reports ESP tunnels to be up when they are not.
- T1171 (bug): 1.2.0 epa2 - IPsec VPN initiation

3.2.51 2021-05-06

- T3519 (bug): Cannot add / assign L2TPv3 to vrf

3.2.52 2021-05-01

- T3379 (feature): Add global-parameters name-server for dhcpv6-server
- T3491 (default): Change Kernel HZ to 1000

3.2.53 2021-04-30

- T3170 (default): Add a sanity check for empty node.def files

3.2.54 2021-04-29

- T3502 (bug): “system ip multipath layer4-hashing” doesn’t work
- T3029 (bug): Generated NGINX configuration is wrong for the redirection (http -> https)
- T3156 (feature): Add op and additional conf commands for ISIS
- T2012 (feature): Global PBR
- T1314 (feature): Allow BGP on unnumbered interfaces

3.2.55 2021-04-28

- T3447 (bug): Default IPv6 route is not created in VRF

3.2.56 2021-04-27

- T3458 (default): vyos docs missing gretap from tunnel section
- T2946 (bug): call to commandd ‘stty_size’ cause show interfaces API to fail.

3.2.57 2021-04-26

- T3487 (bug): Specifying an invalid “interface address” like dhcp leads to commit error

3.2.58 2021-04-25

- T3468 (bug): Tunnel interfaces aren’t suggested as being available for bridging (regression)
- T1802 (feature): Wireguard QR code in cli for mobile devices

3.2.59 2021-04-23

- T3395 (bug): WAN load-balancing fails with nexthop dhcp
- T3290 (bug): Disabling GRE conntrack module fails

3.2.60 2021-04-18

- T3481 (default): Exclude tag node values from key mangling
- T3475 (bug): XML dictionary cache unable to process syntaxVersion elements

3.2.61 2021-04-15

- T3386 (bug): PPPoE-server don't start with local authentication

3.2.62 2021-04-14

- T3055 (bug): op-mode incorrect naming fo ipsec policy-based tunnels

3.2.63 2021-04-12

- T3454 (enhancement): dhclient reject option

3.2.64 2021-04-08

- T3456 (bug): firewall: rules that should be deleted seem to be still in use

3.2.65 2021-04-05

- T1612 (default): dhcp-server time-offset fails to validate
- T3438 (bug): VRF: removing vif which belongs to a vrf, will delete the entire vrf from the operating system
- T3418 (bug): BGP: system wide known interface can not be used as neighbor

3.2.66 2021-04-04

- T3457 (feature): Output the "monitor log" command in a colorful way

3.2.67 2021-03-31

- T3445 (bug): vyos-1x build include not all nodes

3.2.68 2021-03-29

- T3446 (default): Cloudinit error message when empty domain is passed to filter.
- T3432 (default): Azure ssh keys not working for version 1.2.7/1.3.x

3.2.69 2021-03-25

- T2639 (feature): sort output of show vpn ipsec sa

3.2.70 2021-03-24

- T3359 (default): static route table not working properly
- T3307 (default): address prefix destination NAT fails to render nftables rules / commit

3.2.71 2021-03-22

- T3284 (bug): merge/load fail silently if unable to resolve host

3.2.72 2021-03-21

- T3416 (bug): NTP: when running inside a VRF op-mode commands do not work

3.2.73 2021-03-20

- T3392 (bug): vrrp over dhcp default route bug (unexpected vrf)
- T3373 (feature): Upgrade to SaltStack version 3002.5
- T3329 (default): “system conntrack ignore” rules can no longer be created due to an iptables syntax change
- T3300 (feature): Add DHCP default route distance
- T3306 (feature): Extend set route-map aggregator as to 4 Bytes

3.2.74 2021-03-18

- T3411 (default): Extend the redirect_stdout context manager in vyos-configd to redirect stdout from subprocesses
- T3271 (bug): qemu-kvm grub issue

3.2.75 2021-03-17

- T3413 (bug): Configuring invalid IPv6 EUI64 address results in “OSError: illegal IP address string passed to inet_pton”

3.2.76 2021-03-14

- T2271 (feature): OSPF: add per VRF instance support
- T175 (feature): Add source route option to vti interface

3.2.77 2021-03-13

- T3406 (bug): tunnel: interface no longer supports specifying encaps limit none - or migrator is missing
- T3407 (bug): console-server: do not allow to spawn a console-server session on serial port used by “system console”

3.2.78 2021-03-11

- T3399 (bug): RPKI: dashes in hostnames are replaced with underscores when rendering the FRR config
- T3305 (bug): Ingress qdisc does not work anymore in 1.3-rolling-202101 snapshot
- T2927 (bug): isc-dhcpd release and expiry events never execute
- T899 (bug): Tunnels cannot be moved from one bridge to another
- T786 (feature): new style xml and conf-mode scripts: possibility to add tagName value as parameter to conf-script

3.2.79 2021-03-09

- T3389 (default): gretap tunnel type missing from vyos documentation after renamed from gre-bridge
- T3382 (bug): Error creating Console Server

3.2.80 2021-03-08

- T3387 (bug): Command “Monitor vpn ipsec” is not working

3.2.81 2021-03-07

- T3319 (bug): VXLAN uses ttl 1 (auto) by default
- T3391 (feature): Add CLI support for specifying maximum-paths per address family ipv4 unicast and ipv6 unicast
- T3211 (feature): ability to redistribute ISIS into other routing protocols

3.2.82 2021-03-05

- T2659 (feature): Add fastnetmon (DDoS detection) support

3.2.83 2021-03-04

- T2861 (bug): route-map “set community additive” not working correctly

3.2.84 2021-03-03

- T2966 (feature): tunnel: add new encapsulation types ip6tnl and ip6gretap

3.2.85 2021-03-01

- T3342 (bug): On xen-netback interfaces must set “scattergather” offload before MTU>1500

3.2.86 2021-02-28

- T3370 (bug): dhcp: Invalid domain name “private”
- T3369 (feature): VXLAN: add IPv6 underlay support

3.2.87 2021-02-27

- T2291 (bug): Bad hostnames in /etc/hosts with static-mapping in dhcp server config
- T3364 (feature): tunnel: cleanup/rename CLI nodes
- T3368 (feature): macsec: add support for gcm-aes-256 cipher
- T3366 (bug): tunnel: can not change local / remote ip address for gre-bridge tunnel
- T3173 (feature): Need ‘nopmtudisc’ option for tunnel interface

3.2.88 2021-02-26

- T3347 (default): vyos 1.3 beta fails to configure Xen HVM guest ethernet interfaces due to ethtool -g error
- T3357 (default): HTTP-API redirect from http correct https port

3.2.89 2021-02-24

- T1774 (default): Add a show config operation to the HTTP API
- T3303 (feature): Change welcome message on boot

3.2.90 2021-02-21

- T3163 (feature): ethernet ring-buffer can be set with an invalid value
- T2521 (bug): Need to restart pdns-recursor to check new entries in /etc/hosts

3.2.91 2021-02-20

- T2647 (default): ipsec disableuniqueids generate a wrong ipsec.conf

3.2.92 2021-02-19

- T3326 (bug): OSPFv3: Cannot add L2TPv3 interface
- T2061 (bug): protocol logs not sent to remote syslog

3.2.93 2021-02-18

- T3259 (default): many dnat rules makes the vyos http api crash, even showConfig op timeouts

3.2.94 2021-02-17

- T3047 (bug): OSPF : virtual-link and passive-interface default parameters does not work together
- T3312 (feature): SolarFlare NICs support

3.2.95 2021-02-16

- T3318 (feature): Update Linux Kernel to v5.4.135 / 5.10.53

3.2.96 2021-02-14

- T2152 (bug): ddclient has bug which prevents use_web from being used
- T3308 (feature): BGP: add graceful shutdown support

3.2.97 2021-02-13

- T3028 (feature): Create a default user when metadata is not available (for Cloud-init builds)
- T2867 (feature): Cleanup DataSourceOVF.py in the Cloud-init
- T2726 (feature): Allow to use all supported SSH key types in Cloud-init
- T2403 (feature): Full support for networking config in Cloud-init
- T2387 (feature): Create XML scheme for [conf_mode] BGP
- T2174 (feature): Rewrite protocol BGP to new XML/Python style
- T1987 (bug): A default route can be deleted by dhclient-script in some cases
- T2310 (bug): vyos-cloud-init use global config to configure pass and ssh login
- T723 (feature): Add support for first boot or installation time saved config modification
- T1775 (bug): Cloud-init not running userdata runcmd
- T1389 (feature): Add support for NoCloud cloud-init datasource
- T1315 (feature): Allow BGP to use address-family l2vpn evpn

3.2.98 2021-02-12

- T3301 (bug): Wrong format and valueHelp for policy as-path-list regex

3.2.99 2021-02-11

- T2638 (default): FRR: New framework for configuring FRR
- T3035 (enhancement): Allow IPv4 over IPv6 IPsec and vice versa
- T1957 (feature): PPPoE server: maintenance mode
- T1773 (default): Make it possible to export config to JSON

3.2.100 2021-02-08

- T3295 (feature): Update Linux Kernel to v5.4.96 / 5.10.14
- T3292 (bug): RIPng: access-lists/prefix-list reference IPv4 and not IPv6 lists during verification

3.2.101 2021-02-07

- T3293 (bug): RPKI migration script errors out after CLI rewrite

3.2.102 2021-02-06

- T3285 (feature): Schedule reboots through systemd-shutdown instead of atd
- T661 (feature): Show a warning if router going to reboot soon (due to “commit-confirm” command)

3.2.103 2021-02-05

- T2450 (feature): Rewrite “protocols vrf” tree in XML and Python
- T208 (feature): Ability to ignore default-route from dhcpd per interface

3.2.104 2021-02-04

- T2834 (bug): Config rollback function is broken due lack access to the config.boot

3.2.105 2021-02-03

- T3239 (default): XML: override ‘defaultValue’ for mtu of certain interfaces; remove workarounds
- T2910 (feature): XML: generator should support override of variables
- T2873 (bug): “show nat destination translation address” doesn’t filter at all
- T627 (bug): IPSec configuration directive deletion fails, causes bad IPSec state on reboot.

3.2.106 2021-02-02

- T3018 (bug): Unclear behaviour when configuring vif and vif-s interfaces
- T3255 (default): Rewrite protocol RPKI to new XML/Python style

3.2.107 2021-02-01

- T3268 (feature): Add VRF support to VIF-S interfaces
- T3274 (default): ask_yes_no() doesn't handle EOFError

3.2.108 2021-01-31

- T3276 (feature): Update Linux Kernel to v5.4.94 / 5.10.12

3.2.109 2021-01-30

- T3269 (bug): VIF-C interfaces don't verify configuration
- T3240 (feature): Support per-interface DHCPv6 DUIDs
- T3037 (bug): Bgp afi ipv6-unicast capability dynamic bug
- T3273 (default): PPPoE static default-routes deleted on interface down when not added by interface up

3.2.110 2021-01-29

- T3262 (bug): DHCPv6 client runs when dhcpv6-options is configured without requesting an address or PD
- T3261 (bug): Does not possible to disable pppoe client interface.
- T3246 (bug): OSPFv3 router ID not configured in FRR
- T3126 (bug): unsuppress-map doesn't work for BGP IPv4

3.2.111 2021-01-27

- T3257 (feature): tcpdump supporting complete protocol
- T3194 (bug): OSPF redistribution metric issue
- T3110 (bug): Broken pipe in show interfaces
- T3085 (feature): IPv6 BGP Neighbor Weight
- T651 (enhancement): Split CI'ed, VyOS-specific packages and other packages into separate repos
- T597 (enhancement): Code testing on sonarcloud.com
- T516 (default): Make Python / XML code development more testable
- T625 (default): IKEv1 lifetime negotiation in VyOS 1.2.0
- T613 (bug): Missing linux-kbuild
- T505 (bug): Hostapd cannot log

3.2.112 2021-01-26

- T3251 (bug): PPPoE client trying to authorize with the wrong username
- T2859 (bug): show nat source translation - Errors out

3.2.113 2021-01-25

- T3252 (bug): rpki: AttributeError: ‘Config’ object has no attribute ‘return__value’
- T3249 (feature): Support operation mode forwarding table output

3.2.114 2021-01-24

- T3230 (bug): RPKI can’t be deleted
- T3243 (feature): Update Linux Kernel to v5.4.92 / 5.10.10

3.2.115 2021-01-21

- T3237 (bug): DHCP Server Static-Mapping Validation Error

3.2.116 2021-01-18

- T2761 (feature): Extend “show vrrp” op-mode command with router priority
- T2679 (feature): VRRP with BFD Failure Detection
- T3212 (bug): SSH: configuration directory is not always created on boot
- T3231 (bug): “system option ctrl-alt-delete” has no effect

3.2.117 2021-01-17

- T3222 (bug): BGP dampening description
- T2944 (bug): NTP by default listen on any address/interface
- T3226 (bug): Repair bridge smoke test damage
- T2442 (enhancement): Move application of STP settings for bridge members from interfaces-bridge.py to Interface.add_to_bridge()
- T2381 (bug): OpenVPN: openvpn-option parsed/rendered improperly

3.2.118 2021-01-16

- T3215 (bug): show ipv6 route Broken on 1.4 Rolling
- T3172 (bug): Builds sometime after 2020-12-17 have broken routing after reboot
- T3157 (bug): salt-minion fails to start due to permission error accessing /root/.salt/minion.log
- T3167 (default): Recurring bugs in Intel NIC drivers
- T3151 (default): Decide on the final list of packages for 1.3
- T3137 (feature): Let VLAN aware bridge approach the behavior of professional equipment
- T3223 (feature): Update Linux Kernel to v5.4.89 / 5.10.7

3.2.119 2021-01-15

- T3210 (feature): ISIS three-way-handshake
- T3184 (feature): Add correct descriptions for BGP neighbors
- T2850 (feature): Add BGP template for FRR

3.2.120 2021-01-14

- T3218 (feature): Replace Intel out-of-tree drivers with Linux Kernel stock drivers.

3.2.121 2021-01-13

- T3186 (bug): NAT: bug with “!” invert character

3.2.122 2021-01-12

- T3205 (bug): Does not possible to configure tunnel mode gre-bridge

3.2.123 2021-01-11

- T3208 (bug): Does not possible to change user password
- T3198 (bug): OSPF database filtering issue
- T3206 (bug): Unable to delete destination NAT rule
- T3193 (bug): DHCPv6 PD verification issues
- T3201 (bug): show log all Not Working for RADIUS Users

3.2.124 2021-01-10

- T3178 (feature): Migrate vyatta-op-quagga to vyos-1x

3.2.125 2021-01-09

- T2467 (bug): Restarting Flow Accounting Fails
- T3199 (feature): Update Linux Kernel to v5.4.88 / 5.10.6

3.2.126 2021-01-07

- T3192 (feature): login: radius: add support for IPv6 RADIUS servers

3.2.127 2021-01-05

- T3169 (enhancement): Reimplement smoke test of span (mirror)
- T3161 (default): Consider removing ConfigLoad.pm
- T1398 (default): Remove vyatta-config-migrate package
- T805 (enhancement): Drop config compatibility with Vyatta Core older than 6.5

3.2.128 2021-01-04

- T3185 (bug): [conf-mode] Wrong CompletionHelp for Tunnel local-ip
- T3152 (bug): wan-load-balance does not show connections
- T2601 (bug): pppoe-server: does not possible to disable ccp

3.2.129 2021-01-03

- T3180 (bug): DHCP server raises NameError

3.2.130 2021-01-02

- T3175 (bug): Dynamic DNS validations don't reflect supported protocols in ddclient
- T2321 (feature): VRF support for SSH, NTP, SNMP service
- T3177 (bug): Rolling Release no longer reports VMware UUID

3.2.131 2021-01-01

- T3171 (feature): Add CLI option to enable RPS (Receive Packet Steering)

3.2.132 2020-12-31

- T3162 (bug): PPPoE server pado-delay issue
- T3160 (bug): PPPoE server called-sid option does not work
- T3168 (feature): Update Linux Kernel to v5.4.86

3.2.133 2020-12-29

- T3082 (bug): multi_to_list must distinguish between values and defaults
- T1466 (feature): Add EAPOL login support

3.2.134 2020-12-28

- T1732 (feature): Removing vyatta-webproxy module
- T2666 (feature): Packet Processing with eBPF and XDP
- T2581 (default): webproxy: implement proxy chaining
- T563 (feature): webproxy: migrate 'service webproxy' to get_config_dict()

3.2.135 2020-12-27

- T3150 (bug): When configuring QoS, the setting procedure of port mirroring is wrong

3.2.136 2020-12-23

- T3143 (bug): OpenVPN server: Push route does not work
- T3146 (feature): Upgrade FRR from 7.4 -> 7.5 version incl. new libyang
- T3145 (feature): Update Linux Kernel to v5.4.85
- T3147 (feature): Upgrade to SaltStack version 3002.2

3.2.137 2020-12-22

- T3142 (bug): OpenVPN op-command completion issue
- T2940 (feature): Update FRR to 7.4
- T2573 (bug): BFD opmode Commands are broken
- T2495 (feature): Add xml for ISIS [conf_mode]
- T1316 (feature): Support for IS-IS

3.2.138 2020-12-20

- T3131 (bug): Typo in ipsec preshared-secret help
- T3134 (bug): DHCPv6 DUID configuration node missing
- T3140 (feature): Relax "ethernet offload-options" CLI definition
- T3132 (feature): Enable egress flow accounting

3.2.139 2020-12-17

- T2810 (default): Docs for vpn anyconnect-server
- T2036 (default): Open Connect VPN Server () support

3.2.140 2020-12-14

- T3128 (bug): pppoe smoke test failed
- T3129 (feature): Update Linux Kernel to v5.4.83
- T3089 (feature): Migrate port mirroring to vyos-1x and support two-way traffic mirroring
- T3130 (feature): Replace vyos-netplug with upstream debian version

3.2.141 2020-12-13

- T3114 (bug): When the bridge member is a non-ethernet interface, setting VLAN-aware bridge parameters fails

3.2.142 2020-12-11

- T3123 (bug): Configuration of vti interface impossible

3.2.143 2020-12-10

- T3117 (bug): OpenVPN config migration errors upgrading from 1.3-rolling-202010280217 to 1.3-rolling-202012060217

3.2.144 2020-12-09

- T3122 (feature): Update Linux Kernel to v4.19.162
- T3121 (bug): get_config_dict() and key_mangling=('-', '_') Broke PowerDNS dns_forwarding config file

3.2.145 2020-12-08

- T2562 (bug): VyOS can't be used as a DHCP server for a DHCP relay

3.2.146 2020-12-07

- T3120 (bug): 1.3-rolling-202012070217 python error when deleting nat rule
- T3119 (feature): migrate "system ip" to get_config_dict() and provide smoketest

3.2.147 2020-12-05

- T2744 (bug): igmp-proxy issue: Address already in use

3.2.148 2020-12-04

- T3108 (bug): Section Config overlapped match with FRRConfig
- T3112 (feature): PPPoE IPv6: remove "enable" node
- T3100 (feature): Migrate DHCP/DHCPv6 server to get_config_dict()

3.2.149 2020-12-03

- T3105 (bug): static-host-mapping writing in one line
- T3107 (feature): Update Linux Kernel to v4.19.161
- T3104 (bug): LLDP Traceback error

3.2.150 2020-12-01

- T3094 (bug): Can not specify multiple deny ports in FW rule
- T3102 (bug): Destination NAT fails to commit
- T2713 (bug): VyOS must not change permissions on files in /config/auth

3.2.151 2020-11-30

- T3091 (feature): Add “tag” for static route
- T1207 (feature): DMVPN behind NAT

3.2.152 2020-11-29

- T2297 (feature): NTP add support for pool configuration
- T3095 (feature): Migrate dhcp-relay and dhcpv6-relay to get_config_dict()

3.2.153 2020-11-28

- T2890 (bug): NAT error adding translation address range
- T2868 (bug): Tcp-mss option in policy calls kernel-panic
- T3092 (feature): nat: migrate to get_config_dict()

3.2.154 2020-11-27

- T2715 (feature): Duplicate address detection option supporting ARP
- T2714 (feature): A collection of utilities supporting IPv6 or ipv4
- T3088 (feature): Migrate IGMP-Proxy over to get_config_dict() and add smoketests

3.2.155 2020-11-24

- T3087 (feature): Update Linux Kernel to v4.19.160

3.2.156 2020-11-23

- T2177 (default): Commit fails on adding disabled interface to bridge
- T3066 (bug): reboot in - Invalid time
- T2802 (bug): Tunnel interface does not apply EUI-64 IPv6 Address
- T2359 (bug): Adding IPIP6 tun interface to bridge [conf_mode] errors
- T2357 (bug): GRE-bridge conf_mode errors
- T2259 (feature): Support for bind vif-c interfaces into VRFs
- T2205 (bug): “set interface ethernet” fails on Hyper-V
- T2182 (bug): Failure to commit an IPv6 address on a tunnel interface
- T2155 (bug): Cannot set anything on Intel 82599ES 10-Gigabit SFI/SFP+
- T2153 (bug): traceroute circular reference
- T3081 (bug): get_config_dict() does not honor whitespaces in the CLI values field
- T3080 (bug): OpenVPN failing silently for a number of reasons in rolling post Nov/02
- T3074 (bug): openvpn site-to-site doesn't work
- T2542 (bug): OpenVPN client tap interfaces not coming up
- T3084 (bug): wifi: TypeError on “show interfaces wireless info”

3.2.157 2020-11-21

- T3079 (bug): Fix the problem that VLAN 1 will be deleted in VLAN-aware bridge
- T3060 (bug): OpenVPN not working in vyos-1.3-rolling-20201101 and after

3.2.158 2020-11-20

- T3078 (feature): CLI cleanup: rename “system options” -> “system option”
- T2997 (feature): DHCP: disallow/do-not-request certain options when requesting IP address from server
- T3077 (feature): WireGuard: automatically create link-local IPv6 addresses
- T2550 (default): OpenVPN: IPv4 not working in client mode
- T3072 (feature): Migrate tunnel interfaces to new get_config_dict() approach
- T3065 (feature): Add “interfaces wirelessmodem” IPv6 support
- T3048 (feature): Drop static smp-affinity for a more dynamic way using tuned

3.2.159 2020-11-19

- T3067 (bug): Wireless interface can no longer be added to the bridge after bridge VLAN support
- T3075 (feature): Update Linux Kernel to v4.19.158

3.2.160 2020-11-16

- T3003 (enhancement): Extend smoketest framework to allow loading an arbitrary config file

3.2.161 2020-11-15

- T3069 (bug): openvpn - routed networks not available
- T3038 (feature): Supporting AZERTY keyboards
- T2993 (bug): op-mode: lldp: show lldp neighbors - AttributeError: 'str' object has no attribute 'items'
- T2564 (enhancement): Extend VyOS to support appliance LCDs

3.2.162 2020-11-14

- T3041 (bug): Intel QAT: vyos-1.3-rolling-202011020217-amd64 kernel panic during configure

3.2.163 2020-11-13

- T3063 (feature): Add support for Huawei LTE Module ME909s-120
- T3059 (bug): L2TPv3 interface: Enforced to shutdown but no command to enable interface permanently

3.2.164 2020-11-12

- T3064 (feature): Update Linux Kernel to v4.19.157

3.2.165 2020-11-10

- T2103 (bug): Abnormal interface names if VIF present

3.2.166 2020-11-08

- T3050 (bug): Broken address/subnet validation on NAT configuration

3.2.167 2020-11-07

- T2914 (bug): OpenVPN: Fix for IPv4 remote-host hostname in client mode:
- T2653 (feature): "set interfaces" Python handler code improvements - next iteration
- T311 (feature): DHCP: set client-hostname via CLI

3.2.168 2020-11-06

- T3051 (bug): OpenVPN: multiple client routes do not work in server mode
- T3046 (bug): openvpn directory is not auto-created
- T3052 (feature): Update Linux firmware files to 20201022 version
- T2731 (bug): “show interfaces” returns invalid state when link is down

3.2.169 2020-11-05

- T3049 (feature): Update Linux Kernel to v4.19.155
- T2994 (feature): Migrate OpenVPN interfaces to get_config_dict() syntax

3.2.170 2020-11-03

- T3043 (feature): Wireless: Refactor CLI
- T3034 (feature): Add WiFi WPA 3 support
- T2967 (bug): Duplicate IPv6 BFD Peers Created
- T2483 (bug): DHCP most likely not restarting pdns_recursor

3.2.171 2020-11-02

- T3024 (bug): DHCPv6 PD configuration doesn't really render an expected behavior

3.2.172 2020-11-01

- T3036 (feature): OpenVPN remote-address does not accept IPv6 address
- T3032 (feature): Ability to “set table” in the policy route-map
- T2193 (feature): Display disabled VRRP instances in a *show vrrp* output

3.2.173 2020-10-30

- T2790 (feature): Add ability to set ipv6 protocol route-map for OSPFv3
- T3033 (feature): Update Linux Kernel to v4.19.154
- T2969 (bug): OpenVPN: command_set on interface is not applied, if interface doesn't come up in commit

3.2.174 2020-10-28

- T2631 (default): l2tp, sstp, pptp add option to disable radius accounting
- T2630 (feature): Allow Interface MTU over 9000
- T3027 (bug): Unable to update system Signature check FAILED
- T2995 (bug): Enhancements/bugfixes for vyos_dict_search()

- T2968 (feature): Add support for Intel Atom C2000 series QAT

3.2.175 2020-10-27

- T3026 (default): qemu: update script for deprecated ssh_host_port_min/max
- T2938 (feature): Adding remote Syslog RFC5424 compatibility
- T2924 (bug): Using 'set src' in a route-map invalidates it as part of a subsequent boot-up
- T2587 (bug): Cannot enable the interface when the MTU is set to less than 1280
- T2885 (default): config: print commit errors to config session terminal
- T2808 (default): Add smoketest to ensure script consistency with config daemon
- T2582 (default): Script daemon to offload processing during commit
- T1721 (bug): Recursive Next Hop not updated for static routes

3.2.176 2020-10-26

- T3016 (feature): dhcp-server: use better constraint error message on invalid subnet

3.2.177 2020-10-24

- T3007 (default): HTTP-API should use config load script, not backend config load
- T2984 (bug): (igb, ixgbe) HW queues applied only for the first 2 interfaces
- T3009 (bug): vpn l2tp remoteaccess require option broken
- T3010 (bug): ttl option of gre-bridge
- T3005 (bug): Intel: update out-of-tree drivers, i40e driver warning
- T3004 (feature): ConfigSession should (optionally) use config load script
- T2723 (feature): Support tcptraceroute

3.2.178 2020-10-22

- T2978 (bug): IPoE service does not work on shared mode.
- T2906 (bug): OpenVPN: tls-auth missing key direction

3.2.179 2020-10-21

- T2828 (bug): BGP conf_mode error enforce-first-as
- T2749 (bug): Setting ethx configuration issue.
- T2138 (default): Can't load archived configs as they are gzipped

3.2.180 2020-10-20

- T2987 (bug): VxLAN not working properly after upgrading to latest October build (also with newinstallation)
- T2989 (default): MPLS documentation expansion

3.2.181 2020-10-19

- T1588 (bug): VRRP failed to start if any of its interfaces not exist
- T1385 (feature): Allow bonding interfaces to have pseudo-ethernet interfaces
- T3000 (bug): Mismatch between “prefix-length” and “preference” in dhcp6-server syntax
- T2992 (feature): Automatically verify sha256 checksum on ISO download
- T752 (feature): Disable IPv4 forwarding on specific interface only

3.2.182 2020-10-18

- T2965 (feature): Brief BFD Peer Info
- T2907 (feature): OpenVPN: Option to disable encryption
- T2985 (feature): Add glue code to create bridge interface on demand

3.2.183 2020-10-17

- T2980 (bug): FRR bfdd crash due to invalid length
- T2991 (feature): Update WireGuard to 1.0.20200908
- T2990 (feature): Update Linux Kernel to v4.19.152
- T2981 (feature): MPLS LDP neighbor session clear capability
- T2792 (default): Failed to run *sudo make qemu* with vyos-build container due to the change of packer

3.2.184 2020-10-14

- T2972 (bug): PPPoE server rate limiter allows max 65535 kbps to be set

3.2.185 2020-10-13

- T2976 (bug): Client IP pool does not work for PPPoE local users

3.2.186 2020-10-12

- T2951 (bug): monitor nat not working
- T2782 (bug): Changing timezone, does not restart rsyslog

3.2.187 2020-10-11

- T2973 (bug): tftp-server cannot listen on IPv6 address

3.2.188 2020-10-08

- T2891 (feature): Support to change ring-buffers from CLI

3.2.189 2020-10-06

- T2957 (bug): show openvpn not returning anything

3.2.190 2020-10-05

- T2963 (bug): Wireless: WIFI is not password protected when security wpa mode is not defined but passphrase is

3.2.191 2020-10-04

- T2953 (feature): Accel-PPP services CLI config cleanup (SSTP, L2TP, PPPoE, IPoE)
- T2829 (bug): PPPoE server: mppe setting is implemented as node instead of leafNode
- T2960 (feature): sstp: migrate to get_config_dict()

3.2.192 2020-10-03

- T2956 (feature): Add support for list of defaultValues
- T2955 (feature): Update Linux Kernel to v4.19.149

3.2.193 2020-10-02

- T2952 (bug): config: timeout breaks synchronization of messages, causing freeze

3.2.194 2020-10-01

- T2945 (bug): Interface removed from BRIDGE on setting changed
- T2948 (bug): NAT: OSError when configuring translation address range
- T2936 (feature): Migrate PPPoE server to get_config_dict() do reduce boilerplate code

3.2.195 2020-09-30

- T2939 (bug): Wireguard Remove Peer Fails
- T2932 (bug): The second QAT device does not start

3.2.196 2020-09-29

- T2919 (feature): PPPoE server: Called-Station-Id attribute
- T2918 (feature): Accounting interim jitter for pppoe, l2tp, pptp, ipoe
- T2917 (feature): PPPoE server: Preallocate NAS-Port-Id
- T2937 (feature): Update Linux Kernel to v4.19.148

3.2.197 2020-09-27

- T2930 (feature): Support configuration of MAC address for VXLAN and GENEVE tunnel

3.2.198 2020-09-26

- T2902 (bug): “add system image” fails when appending XX to image name
- T2856 (bug): equuleus: *show version all* throws broken pipe exception on abort
- T2482 (enhancement): Update PowerDNS recursor to 4.3.1 for CVE-2020-10995
- T2929 (bug): Upgrading from 1.2 (crux) to 1.3 rolling causes vyos.configtree.ConfigTreeError for RADIUS settings
- T2928 (bug): MTU less then 1280 bytes and IPv6 will raise FileNotFoundError
- T2926 (bug): snmp.py missing an import
- T2912 (feature): When setting MTU check for hardware maximum supported MTU size

3.2.199 2020-09-25

- T2915 (bug): Lost “proxy-arp-pvlan” option for vlan
- T2925 (feature): Update Linux Kernel to v4.19.147
- T2921 (feature): Migrate “service dns forwarding” to get_config_dict() for ease of source maintenance

3.2.200 2020-09-24

- T2896 (bug): set ip route 0.0.0.0/0 dhcp-interface eth0
- T2923 (bug): Configuring DHCPv6-PD without a interface to delegate to raises TypeError

3.2.201 2020-09-23

- T2846 (bug): ip route doesn't show longer-prefixes

3.2.202 2020-09-20

- T2904 (feature): 802.1ad / Q-in-Q ethertype default not utilized
- T2905 (feature): Sync CLI nodes between PPPoE and WWAN interface
- T2903 (feature): Q-in-Q (802.1.ad) ethertype should be defined explicitly and not via its raw value

3.2.203 2020-09-19

- T2894 (bug): bond: lacp: member interfaces get removed once bond interface has vlans configured
- T2901 (feature): Update Linux Kernel to v4.19.146
- T2900 (bug): DNS forwarding: invalid warning is shown for “system name-server” or “system name-servers-dhcp” even if present

3.2.204 2020-09-18

- T945 (bug): Unable to change configuration after changing it from script (vbash + script-template)

3.2.205 2020-09-16

- T2886 (bug): RADIUS authentication broken only returns operator level
- T2887 (bug): WiFi ht40+ channel width is not set in hostaptd.conf

3.2.206 2020-09-15

- T2515 (bug): Ethernet interface is automatically disabled when removing it from bond

3.2.207 2020-09-14

- T2872 (bug): “Show log” for nat and openvpn got inter-mixed
- T2301 (bug): Delete PBR vyatta_policy_ref
- T2880 (feature): Update Linux Kernel to v4.19.145
- T2879 (feature): Cleanup 4.19.144 kernel configuration

3.2.208 2020-09-13

- T2878 (feature): LACP / bonding: new op-mode command: show interfaces bonding bond0 detail
- T2858 (feature): Rewrite dynamic dns client to get_config_dict()
- T2857 (feature): Cleanup Intel QAT configuration script
- T2841 (bug): “monitor bandwidth-test initiate” does not accept IPv6 address as option
- T2877 (feature): LACP / bonding: support configuration of minimum number of links

3.2.209 2020-09-12

- T2863 (default): Wireguard IPv6 Link-Local Addresses Are Not Unique
- T2876 (feature): Update Linux Kernel to v4.19.144

3.2.210 2020-09-10

- T2870 (feature): Update Linux Kernel to v5.8.8

3.2.211 2020-09-09

- T2728 (bug): Protocol option ignored for IPSec peers in transport mode
- T1934 (default): Change default hostname when deploy from OVA without params.
- T1953 (bug): DDNS service name validation rejects valid service names

3.2.212 2020-09-07

- T1729 (default): PIM (Protocol Independent Multicast) implementation

3.2.213 2020-09-06

- T2860 (bug): Update Accel-PPP to fix l2tp CVE

3.2.214 2020-09-02

- T2833 (bug): vyos 1.3-rolling-202008200357 RIP outgoing update filter list no longer operational
- T2849 (bug): vyos.xml.defaults should return a list on multi nodes, by default

3.2.215 2020-08-31

- T2636 (bug): get_config_dict() shall always return a list on <multi/> nodes

3.2.216 2020-08-30

- T2843 (feature): Upgrade Linux Kernel to 5.8 series
- T2814 (default): kernel 5.1+ : NAT : module *nft_chain_nat_ipv4* renamed
- T2839 (feature): Upgrade WireGuard user-space tools and Kernel module
- T2842 (feature): Replace custom “wireguard, wireguard-tools” package with debian-backports version
- T1205 (bug): module pcspkr missing

3.2.217 2020-08-29

- T2836 (default): show system integrity broken in 1.3

3.2.218 2020-08-28

- T2126 (bug): show vpn ipsec sa IPSec - Process NOT Running
- T2813 (bug): NAT: possible to commit illegal source nat without translation
- T1463 (bug): Missing command *show ip bgp scan* appears in command completion

3.2.219 2020-08-27

- T2832 (feature): Migrate vyos-smoketest content into vyos-lx

3.2.220 2020-08-26

- T2830 (default): Migrate “service https” to use `get_config_dict()`
- T2831 (feature): Update Linux Kernel to v4.19.142

3.2.221 2020-08-25

- T2826 (bug): frr: frr python lib error in `replace_section`

3.2.222 2020-08-24

- T2423 (bug): Loadkey scp ssh key errors

3.2.223 2020-08-23

- T2811 (bug): Does not possible to delete vpn anyconnect
- T2823 (bug): VXLAN has state A/D after configuration
- T2812 (default): Add basic smoketest for anyconnect

3.2.224 2020-08-22

- T2822 (feature): Update Linux Kernel to v4.19.141
- T2821 (feature): Support DHCPv6-PD without “address dhcpv6”
- T2677 (feature): Proposal for clearer DHCPv6-PD configuration options

3.2.225 2020-08-20

- T2209 (bug): Documentation has reference to the old ‘user x level admin’ option
- T1665 (default): prefix-list and prefix-list6 rules incorrectly accept a host address where prefix is required
- T2815 (default): Move certbot config directory under `/config/auth`

3.2.226 2020-08-19

- T2794 (bug): op-mode: lldp: “show lldp neighbors” IndexError: list index out of range
- T2791 (feature): “monitor traceroute” has no explicit IPv4/IPv6 support
- T1515 (bug): FRR ospf6d crashes when performing: “show ipv6 ospfv3 database”

3.2.227 2020-08-16

- T2277 (bug): dhclient-script-vyos does not support VRFs
- T2090 (default): Deleting ‘service salt-minion’ causes python TypeError

3.2.228 2020-08-15

- T2797 (feature): Update Linux Kernel to v4.19.139
- T2796 (bug): PPPoE-Server: listen interface is mandatory but validation check is missing

3.2.229 2020-08-14

- T2795 (bug): console server fails to commit

3.2.230 2020-08-12

- T2786 (bug): OSPF Interface Cost
- T2325 (bug): NHRP op-mode errors
- T2227 (feature): MPLS documentation
- T2767 (bug): The interface cannot be disabled for network enabled configuration
- T2316 (bug): DHCP-server op-mode errors

3.2.231 2020-08-11

- T2779 (bug): LLDP: “show lldp neighbors interface” does not yield any result
- T2379 (bug): But when I get DHCPv6 address for interface deletion, script execution error occurs
- T2784 (default): Remove unused arg from host_name.py functions verify and get_config

3.2.232 2020-08-10

- T2780 (feature): Update Linux Kernel to v4.19.138

3.2.233 2020-08-08

- T2716 (bug): Shaper-HFSC shapes but does not control latency correctly
- T2497 (default): Cache config string during commit
- T2501 (bug): Cannot recover from failed boot config load
- T1974 (feature): Allow route-map to set administrative distance
- T1949 (bug): Multihop IPv6 BFD is unconfigurable

3.2.234 2020-08-04

- T2758 (bug): router-advert: 'infinity' is not a valid integer number
- T2637 (bug): Vlan is not removed from the system
- T1194 (bug): cronjob is being setup even if not saved
- T1287 (bug): No DHCPv6 leases reported for "show dhcpv6 client leases"

3.2.235 2020-08-03

- T2241 (default): Changing settings on an interface causes it to fall out of bridge
- T2757 (bug): "show system image version" contains additional new-line character breaking output
- T1826 (bug): Misleading message on "reboot at" command
- T1511 (default): Rewrite ethernet setup scripts to python
- T1600 (default): Convert 'ping' operation from vyatta-op to new syntax
- T1486 (bug): Unknown LLDP version reported to peers
- T1414 (enhancement): equuleus: buster: 10-unmountfs.chroot fail under apply
- T1076 (bug): SSH: make configuration (sshd_config) volatile and store it to /run
- T770 (bug): Bonded interfaces get updated with incorrect hw-id in config.
- T2724 (feature): Support for IPv6 Toolset
- T2323 (bug): LLDP: "show lldp neighbors detail" returns warnings when service is not configured
- T1754 (bug): DHCPv6 client is impossible to restart

3.2.236 2020-08-02

- T2756 (feature): Accel-PPP: make RADIUS accounting port configurable

3.2.237 2020-08-01

- T2752 (bug): Exception when configuring unavailable ethernet interface
- T2751 (feature): Update Linux Kernel to v4.19.136
- T2753 (feature): Rewrite "add system image" op mode commands in XML
- T2690 (feature): Add VRF support to the add system image command

3.2.238 2020-07-30

- T2746 (feature): IPv6 link-local addresses not configured
- T2678 (bug): High RAM usage on SSH logins with lots of IPv6 routes in the routing table.
- T2701 (bug): *vpn ipsec pfs enable* doesn't work with IKE groups
- T2745 (feature): router-advert: migrate to `get_config_dict()`

3.2.239 2020-07-29

- T2743 (feature): WireGuard: move key migration from config script to migration script
- T1241 (bug): Remove of policy route throws CLI error
- T2742 (feature): mDNS repeater: migrate to `get_config_dict()`

3.2.240 2020-07-28

- T1117 (feature): 'show ipv6 bgp route-map' missing
- T928 (feature): pimd support

3.2.241 2020-07-27

- T2729 (feature): Pseudo-ethernet replace fail message.
- T1249 (feature): multiply PBR rules can set to a single interface
- T1956 (feature): PPPoE server: support PADO-delay
- T1295 (feature): FRR: update documentation
- T1222 (bug): OSPF routing problem - route looping
- T1158 (bug): Route-Map configuration dropped updating `rc11` to `epa2`
- T1130 (bug): Deleting BGP communities from prefix does not work
- T1086 (bug): Configs not saving
- T2067 (feature): pppoe-server: Add possibility set multiple service-name

3.2.242 2020-07-26

- T2734 (feature): WireGuard: fwmark CLI definition is inconsistent
- T2733 (feature): Support MTU configuration on pseudo ethernet devices
- T2644 (default): Disabling Bonded Interfaces Broken
- T2476 (bug): Bond member description change leads to network outage
- T2443 (feature): NHRP: Add debugging information to syslog
- T2021 (bug): OSPFv3 doesn't support decimal area syntax
- T1901 (bug): Semicolon in values is interpreted as a part of the shell command by validators
- T2000 (bug): strongSwan does not install routes to table 220 in certain cases

- T2091 (bug): swanctl.conf file is not generated properly is more than one IPsec profile is used
- T1983 (feature): Expose route-map when BGP routes are programmed in to FIB
- T1973 (feature): Allow route-map to match on BGP local preference value
- T1853 (bug): wireguard - disable peer doesn't work
- T832 (bug): *show monitoring protocols bgp* doesn't work with frr
- T1985 (feature): pppoe: Enable ipv6 modules without configured ipv6 pools

3.2.243 2020-07-25

- T2730 (feature): Update Linux Kernel to v4.19.134
- T2106 (bug): Wrong interface states after reboot
- T1507 (default): cli: logical redundancy with boolean type

3.2.244 2020-07-24

- T2097 (bug): Problems when using <path> as completion helper in op-mode
- T2092 (bug): dhcp-server rfc3442 static route should add default route
- T1817 (bug): BGP next-hop-self not working.
- T1462 (bug): Upgrade path errors 1.1.8 to 1.2.1-S2
- T1372 (bug): Diff functionality behaves incorrectly in some cases
- T2073 (feature): ipoe-server: reset op-mode command for sessions
- T1715 (bug): System DNS Server Order Incorrect

3.2.245 2020-07-23

- T2673 (bug): After the bridge is configured with Mac, bridge is automatically disabled
- T2626 (bug): Changing pseudo-ethernet mode, throws CLI error
- T2608 (bug): delete pseudo-ethernet failed (another error type)
- T2527 (bug): bonding: the last slave interface is not deleted
- T2358 (bug): ip6ip6 bridge conf_mode errors
- T2346 (bug): Setting Hostname Returns Error
- T2330 (bug): Vpn op-mode syntax
- T2188 (default): NTP op-mode commands don't work

3.2.246 2020-07-22

- T2718 (bug): ntp.conf updated incorrectly.
- T2658 (bug): Interface description comment display error
- T2643 (bug): Show Interface Command Issues

- T2725 (bug): Recent 1.3 rolling (since May) fail to load config if user has no password - KeyError: 'password_encrypted'
- T2707 (default): Allow alternative initialization data for Config

3.2.247 2020-07-20

- T2709 (bug): Destination NAT translation port without address fails to commit
- T2717 (default): Wrong DHCP server pool size in statistics
- T2519 (bug): Broadcast address does not add automatically

3.2.248 2020-07-19

- T2708 (bug): “show flow-accounting” should not display script’s “usage” help
- T2592 (default): dhcp-relay discarding packets on valid interfaces
- T2712 (feature): udp-broadcast-relay: service no longer starts
- T2706 (feature): Support NDP protocol monitoring

3.2.249 2020-07-18

- T2704 (bug): connect/disconnect Missing newline in op-mode tab completion helper
- T2689 (feature): Add helper functions to query changes between session and effective configs
- T2585 (bug): Unable to access the Internet after opening PPPoE on-demand dialing

3.2.250 2020-07-15

- T2675 (bug): DNS service failed to start
- T2596 (feature): Allow specifying source IP for ‘add system image’

3.2.251 2020-07-12

- T1575 (default): *show snmp mib ifmib* crashes with IndexError
- T2696 (bug): Some bugfixes of vyatta-wanloadbalance

3.2.252 2020-07-11

- T2687 (feature): SNMP: change logic on v3 password encryption
- T2693 (bug): Dhcp6c cannot be restarted after PPPoE link is reset

3.2.253 2020-07-08

- T2692 (bug): Evaluate Setting Default Hash Policy to L3+L4
- T2646 (bug): Sysctl for IPv4 ECMP Hash Policy Not Set

3.2.254 2020-07-07

- T2691 (bug): Upgrade from 1.2.5 to 1.3-rolling-202007040117 results in broken config due to case mismatch
- T2389 (bug): BGP community-list unknown command
- T2686 (bug): FRR: BGP: large-community configuration is not applied properly after upgrading FRR to 7.3.x series

3.2.255 2020-07-06

- T2680 (bug): Dhcp6c service can not recover when it fails.

3.2.256 2020-07-05

- T2684 (feature): Update Linux Kernel to v4.19.131
- T2685 (feature): Update Accel-PPP to fix SSTP client issues
- T2681 (bug): PPPoE stops negotiating IPv6

3.2.257 2020-07-04

- T2682 (bug): VRF aware services - connection no longer possible after system reboot

3.2.258 2020-07-03

- T2670 (default): Remove dependency on show_config from get_config_dict
- T2676 (feature): NTP: migrate to get_config_dict() implementation

3.2.259 2020-07-02

- T2668 (default): get_config_dict: add get_first_key arg to utility function get_sub_dict

3.2.260 2020-07-01

- T2662 (default): get_config_dict includes node name as key only for tag and leaf nodes
- T2667 (feature): get_config_dict: Use utility function for non-empty path argument

3.2.261 2020-06-28

- T2660 (bug): XML: Python default dictionary does not obey underscore (_) when flat is False

3.2.262 2020-06-27

- T2656 (bug): XML: Python default dictionary returns wrong dictionary level(s)

3.2.263 2020-06-26

- T2642 (bug): sshd Broken on Latest Rolling Release
- T2588 (default): Add support for default values to the interface-definition format
- T2622 (bug): An issue with config migration (interface pseudo ethernet)
- T2057 (feature): Generalised Interface configuration
- T2625 (feature): Provide generic Library for package builds

3.2.264 2020-06-25

- T2487 (bug): VRRP does not display info when group disabled
- T2329 (bug): Show remote config openvpn
- T2165 (bug): When trying to add route to ripng it complains that ip address should be IPv4 format.
- T2159 (default): webproxy log read from wrong file
- T2101 (feature): Fix VXLAN config option parsing
- T2062 (bug): Wrong dhcp-server static route subnet bytes
- T1986 (bug): Python configuration manipulation library leaks open files
- T1762 (bug): VLAN interface configuration fails after internal representation of edit level was switched from a string to a list
- T1538 (bug): Update conntrack-sync packages to fix VRRP issues
- T1808 (feature): add package nftables

3.2.265 2020-06-24

- T2634 (feature): remove autogeneration of interface “ip section” from vyatta-cfg-system
- T2633 (bug): Error with arp_accept on tun interface
- T2595 (feature): Update Linux Kernel to v4.19.128
- T1938 (bug): syslog doesn’t start automatically

3.2.266 2020-06-23

- T2632 (bug): WireGuard: Can not use only one preshared-key for one peer
- T1829 (bug): Install Image script does not respect size of partition greater than 2G but less than disk size
- T2635 (feature): SSH: migrate to get_config_dict()

3.2.267 2020-06-22

- T2486 (bug): DNS records set via ‘system static-host-mapping’ return NXDOMAIN from ‘service dns forwarding’ after a request to a forwarded zone
- T2463 (bug): DHCP-received nameserver not added to vyos-hostsd

- T2534 (bug): pdns-recursor override.conf error
- T2054 (bug): Changing “system name-server” doesn’t update dns forwarding config, neither does “restart dns forwarding”
- T2225 (default): PIM/IGMP documentation

3.2.268 2020-06-21

- T2624 (feature): Serial Console: fix migration script for configured powersave and no console
- T2610 (bug): default-lifetime is not reflected in the RA message
- T2299 (feature): login radius-server priority
- T1739 (bug): Serial interface seems not to be deleted properly
- T480 (bug): Error if no serial interface is present (/dev/ttyS0: not a tty)

3.2.269 2020-06-20

- T2621 (bug): show interfaces repeats interface description if it is longer then an arbitrary number of characters
- T2618 (default): Conversion from 1.2 to 1.3 lost RADVD prefix autonomous-flag setting

3.2.270 2020-06-19

- T2589 (bug): delete pseudo-ethernet failed
- T2490 (feature): Add serial (rs232) to ssh bridge service

3.2.271 2020-06-18

- T2614 (default): Add an option to mangle dict keys to vyos.config.get_config_dict()
- T2026 (default): Make cli-shell-api correctly exit with non-zero code on failures
- T1868 (default): Add opportunity to get current values from API

3.2.272 2020-06-17

- T2478 (feature): login radius: use NAS-IP-Address if defined source address
- T2141 (bug): Static ARP is not applied on boot
- T2609 (bug): router-advert: radvd does not start when lifetime is improperly configured
- T1720 (feature): support for more ‘show ip route’ commands

3.2.273 2020-06-16

- T2604 (default): Remove use of is_tag in system-syslog.py
- T2605 (bug): SNMP service is not disabled by default
- T2568 (bug): Add some missing checks in config

- T2156 (default): PIM op-mode commands

3.2.274 2020-06-15

- T2600 (bug): RADIUS system login configuration rendered wrongly
- T2599 (bug): “show interfaces” does not list VIF interfaces in ascending order
- T2591 (bug): show command has wrong interfaces ordering
- T2576 (bug): “show interfaces” does not return VTI

3.2.275 2020-06-14

- T2354 (bug): Wireless conf_mode errors
- T2593 (bug): source NAT translation port can not be set when translation address is set to masquerade
- T2594 (default): Missing firmware for iwlwifi

3.2.276 2020-06-11

- T2578 (bug): ipaddrcheck unaware of /31 host addresses - can no longer assign /31 mask to interface addresses
- T2571 (bug): NAT destination port with ! results in error
- T2570 (feature): Drop support for “system console device <device> modem”
- T2586 (bug): WWAN default route is not installed into VRF
- T2561 (feature): Drop support for “system console netconsole”
- T2569 (feature): Migrate “set system console” to XML and Python representation

3.2.277 2020-06-10

- T2575 (bug): pppoe-server: does not possibly assign IP address
- T2565 (bug): Does not possible connect to l2tp server with radius auth
- T2553 (bug): Regression: set interface ethN vif-s nnnn does not commit on 1.3-rolling-202006050621

3.2.278 2020-06-08

- T2559 (feature): Add operational mode command to retrieve hardware sensor data

3.2.279 2020-06-07

- T2529 (feature): WWAN: migrate from ttyUSB device to new device in /dev/serial/by-bus
- T2560 (feature): New op-mode command to display information about USB interfaces

3.2.280 2020-06-05

- T2548 (bug): Interfaces allowing inappropriate network addresses to be assigned
- T1958 (default): Include only firmware we actually need

3.2.281 2020-06-04

- T2514 (enhancement): “mac” setting for bond members

3.2.282 2020-06-02

- T2129 (feature): XML schema: tagNode not allowed on first level in new XML op-mode definition
- T2545 (feature): Show physical device offloading capabilities for specified ethernet interface
- T2544 (feature): Enable Kernel CONFIG_KALLSYMS
- T2543 (feature): Kernel: always build perf binary but ship as additional deb package to not bloat the image
- T1096 (bug): BGP process memory leak

3.2.283 2020-06-01

- T2535 (feature): Update Intel QAT drivers to 1.7.1.4.9.0-00008
- T2537 (feature): Migrate “show log dns” from vyatta-op to vyos-1x
- T2536 (bug): “show log dns forwarding” still refers to dnsmasq
- T2538 (feature): Update Intel NIC drivers to recent release (preparation for Kernel >=5.4)
- T2526 (feature): Wake-On-Lan CLI implementation

3.2.284 2020-05-31

- T2532 (feature): VRF aware OpenVPN

3.2.285 2020-05-30

- T2388 (feature): template rendering should create folder and set permission
- T2531 (feature): Update Linux Kernel to v4.19.125
- T2530 (bug): Error creating VRF with a name of exactly 16 characters
- T2460 (default): Migrate vyatta-nat-translations.pl to Python

3.2.286 2020-05-29

- T2528 (bug): “update dns dynamic” throws FileNotFoundError excepton

3.2.287 2020-05-28

- T1291 (default): Under certain conditions the VTI will stay forever down

3.2.288 2020-05-27

- T2395 (feature): HTTP API move to flask/flask-restx as microframework
- T1121 (bug): Can't search for prefixes by community: Community malformed: AA:NN

3.2.289 2020-05-26

- T2520 (bug): Show conntrack fail
- T2502 (bug): PPPoE default route not installed for IPv6 when "default-route auto"
- T2458 (feature): Update FRR to 7.3.1
- T2506 (feature): DHCPv6-PD add prefix hint CLI option

3.2.290 2020-05-25

- T2391 (bug): pppoe-server session-control does not work
- T2269 (feature): SSTP specify tunnels names
- T1137 (bug): 'sh ip bgp sum' being truncated

3.2.291 2020-05-22

- T2491 (feature): MACsec: create CLI for replay protection
- T2489 (feature): Add MACsec interfaces to "show interfaces" output
- T2201 (feature): Rewrite protocol BGP [op-mode] to new XML/Python style
- T2492 (feature): Do not set encrypted user password when it is not changed
- T2496 (feature): Set default to new syntax for config file component versions
- T2493 (feature): Update Linux Kernel to v4.19.124
- T2380 (bug): After PPPoE 0 is restarted, the default static route is lost

3.2.292 2020-05-21

- T1876 (bug): IPSec VTI tunnels are deleted after rekey and dangling around as A/D
- T2488 (feature): Remove logfile for dialup interfaces like pppoe and wwan
- T2475 (bug): linting
- T1820 (bug): VRRP transition scripts for sync-groups are not supported in VyOS (anymore)
- T2364 (default): Add CLI command for mroute
- T2023 (feature): Add support for 802.1ae MACsec

3.2.293 2020-05-20

- T2480 (bug): NAT: after rewrite commit tells that dnat IP address is not locally connected
- T103 (bug): DHCP server prepends shared network name to hostnames

3.2.294 2020-05-19

- T2481 (feature): WireGuard: support tunnel via IPv6 underlay
- T421 (bug): VyOS lacks DHCPv6-PD (Prefix delegation) length / IA_PD support
- T815 (feature): Add DHCPv6 prefix-delegation support

3.2.295 2020-05-17

- T2471 (feature): PPPoE server: always add AdvAutonomousFlag when IPv6 is configured
- T2409 (default): At boot, effective config should not be equal to current config

3.2.296 2020-05-16

- T2466 (bug): live-build encounters apt dependency problem when building with local packages
- T2470 (feature): Update to PowerDNS recursor 4.3
- T2469 (feature): Update Linux Kernel to v4.19.123
- T2198 (default): Rewrite NAT in new XML/Python style

3.2.297 2020-05-15

- T2449 (bug): 'ipv6 address autoconf' and 'address dhcpv6' don't work because interfaces have accept_ra=1 (they should have accept_ra=2 when forwarding=1)

3.2.298 2020-05-14

- T2456 (bug): netflow source-ip cannot be configured

3.2.299 2020-05-13

- T2435 (bug): Pseudo-ethernet Interfaces Broken
- T2294 (bug): ipoe-server broken (jinja2 template issue)

3.2.300 2020-05-12

- T2454 (feature): Update Linux Kernel to v4.19.122
- T2392 (bug): SSTP with ipv6

3.2.301 2020-05-10

- T2445 (bug): VRF route leaking for ipv4 not working
- T2372 (bug): VLAN: error on commit if main interface is disabled
- T2439 (bug): Configuration dependency problem, unable to load complex configuration after reboot

3.2.302 2020-05-09

- T2427 (default): Interface addressing broken since fix for T2372 was merged
- T2438 (default): isc-dhcp-server(6).service reports startup success immediately even if dhcpd fails to start up
- T2367 (default): Flush addresses from bridge members

3.2.303 2020-05-08

- T2441 (bug): TZ validator has a parse error
- T2429 (bug): Vyos cannot apply VLAN sub interface to bridge

3.2.304 2020-05-06

- T2402 (bug): Live ISO should warn when configuring that changes won't persist

3.2.305 2020-05-05

- T1899 (bug): Unionfs metadata folder is copied to the active configuration directory

3.2.306 2020-05-04

- T2412 (bug): ping flood does not work
- T701 (bug): LTE interface doesn't come up
- T951 (bug): command 'isolate-stations true/false' does not make any changes in the hostapd.conf

3.2.307 2020-05-03

- T2420 (feature): Update Linux Kernel to v4.19.120
- T2406 (feature): DHCPv6 CLI improvements
- T2421 (feature): Update WireGuard to Debian release 1.0.20200429-2_bpo10+1

3.2.308 2020-05-02

- T2414 (feature): Improve runtime from Python numeric validator
- T2413 (feature): Update Linux Kernel to v4.19.119

3.2.309 2020-05-01

- T2411 (feature): op-mode: make “monitor traceroute” VRF aware
- T2347 (bug): During commit, any script output directed to stdout will contain path
- T2239 (default): build-vmware-image script ignores the predefined file path, uses the environment variable unconditionally.

3.2.310 2020-04-29

- T2399 (bug): op-mode “dhcp client leases” does not return leases
- T2398 (bug): op-mode “dhcp client leases interface” completion helper misses interfaces
- T2394 (feature): dhcpv6 client does not start
- T2393 (feature): dhclient: migrate from SysVinit to systemd
- T2268 (bug): DHCPv6 is broken

3.2.311 2020-04-28

- T1227 (bug): rip PW can't be set at interface config

3.2.312 2020-04-27

- T2373 (feature): Required auth options for pppoe-server
- T1381 (feature): Enable DHCP option 121 processing
- T2010 (bug): Reboot at reports wrong time or missing timezone

3.2.313 2020-04-26

- T2386 (bug): salt: upgrade to 2019.2 packages
- T2385 (bug): salt-minion: improve completion helpers
- T2384 (bug): salt-minion: log to syslog and remove custom logging option
- T2383 (feature): Update Linux Kernel to v4.19.118
- T2382 (bug): salt-minion: Throws KeyError on commit
- T2350 (bug): Interface geneve conf-mode error

3.2.314 2020-04-25

- T2304 (feature): “system login” add RADIUS VRF support
- T1842 (bug): Equuleus: “reboot at 04:00” command not working

3.2.315 2020-04-24

- T2375 (feature): WireGuard: throw exception if address and port are not given as both are mandatory
- T2348 (bug): On IPv6 address distribution and DHCPv6 bugs

3.2.316 2020-04-23

- T2369 (feature): VRF: can not leak interface route from default VRF to any other VRF
- T2368 (bug): VRF: missing completion helper when leaking to default table
- T2374 (bug): Tunnel interface can not be disabled
- T2362 (default): IPv6 link-local addresses missing due to EUI64 address code, causing router-advert not to work
- T2345 (default): IPv6 router-advert not working

3.2.317 2020-04-22

- T2361 (bug): Unable to delete VLAN vif interface
- T2339 (bug): OpenVPN: IPv4 no longer working after adding IPv6 support
- T2331 (bug): VRRP op-mode errors
- T2320 (bug): Wireguard creates non-existing interfaces in [op-mode].
- T2096 (feature): Provide “generate” and “show” commands via the http API
- T2351 (feature): Cleanup PPTP server implementation and CLI commands

3.2.318 2020-04-21

- T2341 (bug): Pseudo-ethernet Interfaces Not Loaded on Boot
- T2270 (bug): using load with scp/sftp and a username and password does not work
- T2255 (bug): DNS forwarding op-mode error
- T1907 (bug): Traceback on a non-existent interface.
- T2204 (feature): Support tunnel source-interface

3.2.319 2020-04-20

- T2335 (bug): Unable to assign IPv6 from ISP
- T2317 (bug): l2tp overwriting ipsec config files
- T2292 (bug): Ensure graceful shutdown of vyos-http-api
- T2344 (bug): PPPoE server client static IP assignment silently fails

3.2.320 2020-04-19

- T2337 (default): hw-id gone missing from interfaces after upgrade to 1.3-rolling-202004191028
- T2340 (feature): Remove informational “sg” messages from syslog
- T2338 (bug): Can’t delete static IPv6 route on vrf
- T2336 (bug): OpenVPN service fails to start
- T2308 (default): openvpn op-mode scripts broken after migrating to systemd service
- T2185 (default): Start daemons with systemd units instead of with start-stop-daemon

3.2.321 2020-04-18

- T2318 (bug): dns-forwarding migrationscript broken
- T2319 (feature): Update Linux Kernel to v4.19.116
- T2314 (feature): Cleanup PPPoE server implementation and CLI commands
- T2313 (bug): Accel-PPP / PPPoEserver raises “Floating point exception” when not all limits are defined
- T2312 (feature): Use LED modules to enable more visible feedback on VyOS hardware chassis
- T2306 (feature): Add new cipher suites to the WiFi configuration
- T2286 (default): IPoE server vulnerability
- T2224 (feature): Update Linux Kernel to v4.19.114
- T2110 (feature): RADIUS: supply include file for radius config to have a uniform CLI
- T1874 (bug): FRR crashing triggered by RPKI
- T2324 (feature): Cleanup IPoE server implementation and CLI commands

3.2.322 2020-04-17

- T2275 (bug): flow-accounting broken in rolling
- T2256 (feature): Accel-ppp op-mode syntax

3.2.323 2020-04-16

- T2295 (bug): Passwords with Special Characters Broken
- T2305 (feature): Add release name to “show version” command
- T2235 (default): OpenVPN server client IP doesn’t reserve that IP in the pool
- T149 (feature): IPv6 support in OpenVPN tunnel

3.2.324 2020-04-15

- T2293 (bug): OpenVPN: UnboundLocalError after merging server_network PullRequest
- T2298 (bug): Errors PDNS with name-server set

3.2.325 2020-04-14

- T2213 (bug): vyos-1x: WiFi mode ieee80211ac should also activate ieee80211n

3.2.326 2020-04-13

- T2283 (default): openvpn not starting: ccd path in template not moved to /run/openvpn/ccd
- T2236 (bug): DMVPN broken after tunnel rewrite to XML/Python
- T2284 (default): Upgrade ddclient to 3.9.1 which also brings systemd files
- T2282 (feature): Clarify hw-id in ethernet and wireless interface nodes
- T611 (feature): Static route syntax should reflect *ip* command routing capabilities, if possible.

3.2.327 2020-04-12

- T2273 (default): OpenVPN no longer starts in latest rolling, migrate to systemd
- T2263 (feature): Reset feature for SSTP sessions
- T2262 (bug): Broken reset commands for pptp and l2tp
- T2059 (default): Set source-validation on bond vif don't work
- T2276 (default): PPPoE server vulnerability
- T1490 (bug): BGP configuration (is lost/not applied) when updating 1.1.8 -> 1.2.1
- T1828 (bug): Missing completion helper for "set system syslog host 192.0.2.1 facility all protocol"
- T2031 (bug): pseudo-ethernet link interface can not be changed

3.2.328 2020-04-11

- T2264 (feature): l2tp: cleanup CLI definition
- T2233 (bug): Typos in wlanX.cfg
- T2238 (bug): After re-writing list_interfaces.py to use Interfaces() pseudo-ethernet is missing

3.2.329 2020-04-10

- T2265 (feature): DHCP to be an attribute of the class instead of a inheritance
- T2261 (bug): "client-config-dir" not being set for openvpn in 1.3-rolling-202004090909
- T2248 (bug): PPPoE Broken in Latest 1.3 Rolling (1.3-rolling-202004070629)
- T1629 (bug): IP addresses configured on vif-s interfaces are not added to the system
- T2266 (default): openvpn bridged client-server doesn't work (validation error)
- T2253 (default): Fix use of cmd in merge config and remote function helpers

3.2.330 2020-04-09

- T2260 (feature): vxlan, pseudo-ethernet: convert link nodes to source-interface
- T2252 (bug): HTTP API add system image can return ‘504 Gateway Time-out’
- T2172 (feature): Enable conf VXLAN without remote address
- T2237 (bug): l2tp, pptp, pppoe wrong chap-secrets file

3.2.331 2020-04-08

- T2244 (feature): WireGuard: cleanup Python implementation and reduce amount of boilerplate code
- T2186 (feature): Provide more information to the user when a traceback is reported to the user
- T2246 (bug): LLDP op-mode error
- T2240 (feature): Support for bind vif-c interfaces into VRFs
- T2160 (feature): Allow restricting HTTP API to specific virtual hosts
- T2247 (feature): WireGuard: add VRF support

3.2.332 2020-04-05

- T2228 (bug): WireGuard does not allow ports < 1024 to be used
- T2212 (bug): vyos-1x: WiFi card antenna count not set accordingly
- T2230 (feature): Split out inlined Jina2 template to data/templates folder
- T2206 (feature): Split WireGuard endpoint into proper host and port nodes
- T2032 (bug): Monitor bandwidth bits

3.2.333 2020-04-04

- T2158 (bug): Commit fails if ethernet interface doesn’t support flow control (pause)
- T2221 (bug): Ability to remove a VRF that has a next-hop-vrf as target
- T2211 (bug): vyos-1x: VHT channel width not set accordingly
- T2208 (bug): vyos-1x: commit on interfaces wireless wlanX capabilities vht link-adaptation (bothunsolicited) fails
- T2183 (bug): Number of bugs with wireguard script due to interface rearrangement.
- T2104 (default): ifconfig.py size
- T2028 (feature): Convert “interfaces tunnel” to new XML/Python representation
- T2219 (bug): VRF default route of PPPoE and WWAN interfaces do not get added into proper routing table
- T2222 (default): openvpn: requires “multihome” option to listen on all addresses with udp protocol

3.2.334 2020-04-02

- T2072 (bug): Shell autocomplete of option (config node) with quoted value doesn't work
- T1823 (feature): l2tpv3 interface migration fails
- T2202 (feature): Update PowerDNS recursor to 4.2 series
- T2200 (feature): Add VRF support on wirelessmodem interfaces

3.2.335 2020-03-31

- T2166 (bug): Broken proxy-arp on vif
- T2069 (bug): PPPoE-client does not works with service-name option
- T2180 (bug): get_config_dict should be independent of CLI edit level
- T2053 (default): Update vyos-load-config.py for version string syntax change
- T2052 (default): Update vyos-merge-config.py for version string syntax change
- T2144 (default): vyos-build: docker: selection of text in the terminal still selects it in vim (mouse isn't completely disabled)

3.2.336 2020-03-30

- T2176 (default): 'WiFiIf' object has no attribute 'set_state'
- T2029 (feature): Switch to new syntax for config file component versions

3.2.337 2020-03-29

- T2178 (bug): VRF interface don't get removed when VRF is deleted
- T2170 (feature): Add ability to create static route from default to VRF
- T1831 (feature): Denest IPv6 router-advert from Interfaces to general service

3.2.338 2020-03-28

- T2167 (bug): vyos.ifconfig.get_mac() broken
- T2151 (default): wireless: can't delete interface present in config but not present in system
- T1988 (feature): Migrate wirelessmodem to new XML/Python style interface

3.2.339 2020-03-27

- T2164 (bug): Package libstrongswan-standard-plugins missing from image
- T2105 (bug): wireless: not possible to disabled wlan0
- T2169 (default): Remove redundant use of show_config in vyos-merge-config

3.2.340 2020-03-26

- T2162 (default): migration script for router-advert sets link-mtu 0 on bridge interfaces
- T1735 (bug): Issue in “show vpn ipsec/ike sa” output with ipsec encryption algorithm aes128gcm128/aes256gcm128/chacha etc

3.2.341 2020-03-25

- T2148 (default): openvpn: setting “server client” config without “server client ip” results in ValueError: “ does not appear to be an IPv4 or IPv6 address
- T2146 (default): openvpn: “delete server client” doesn’t delete the corresponding ccd configs

3.2.342 2020-03-24

- T2157 (default): Organize service https listen-address/listen-port/server-name under ‘virtual-host’ node
- T1845 (bug): syslog host no longer accepts a port

3.2.343 2020-03-22

- T2150 (feature): SSTP ssl certificates can only be stored in /config/user-data/sstp
- T2149 (feature): Update Linux Kernel to v4.19.112
- T1884 (default): Keeping VRRP transition-script native behaviour and adding stop-script
- T1020 (bug): OSPF Stops distributing default route after a while
- T476 (enhancement): Start builds for Debian 10 (Buster)

3.2.344 2020-03-21

- T2142 (bug): vyos-build: Add required packages and step to build-GCE-image script
- T1870 (feature): Extend Pipeline scripts to support PullRequests
- T1936 (feature): pppoe-server CLI control features

3.2.345 2020-03-20

- T2006 (bug): SSTP RADIUS CLI accepts invalid values
- T2140 (default): openvpn: tls file check function checkCertHeader returns True even when no match is found
- T2007 (feature): SSTP accepts client MTU up to 16384 bytes
- T2008 (feature): Adjustment of SSTP CLI to be more consistent to the rest of VyOS

3.2.346 2020-03-19

- T2135 (bug): Login banner missing spacing now
- T2132 (feature): Document kernel boot parameter ‘vyos-config-debug’
- T1744 (default): Config load fails in ConfigTree with ValueError: Failed to parse config: lexing: empty token
- T1301 (default): bgp peer-groups don’t work when “no-ipv4-unicast” is enabled.

3.2.347 2020-03-17

- T2134 (bug): VXLAN: *NameError: name ‘config’ is not defined*

3.2.348 2020-03-16

- T1803 (bug): Unbind NTP while it’s not requested. . .
- T2131 (feature): Improve syslog remote host CLI definition

3.2.349 2020-03-15

- T2122 (feature): Update Intel out-of-tree drivers to latest version(s)
- T2121 (feature): Update Linux Kernel to v4.19.109
- T2119 (bug): Error on boot when removing ethernet interface from VM
- T1970 (bug): Correct adding interfaces on boot
- T1967 (bug): BGP parameter “enforce-first-as” does not work anymore
- T1432 (enhancement): Implement config write API for Python
- T1431 (feature): Implement an HTTP API for config reading and modification
- T2120 (bug): “reset vpn ipsec-peer” doesn’t work with named peers
- T2001 (bug): Error when router reboot
- T1891 (bug): Router announcements broken on boot
- T1832 (feature): radvd adding feature DNSSL branch.example.com example.com to existing package

3.2.350 2020-03-14

- T834 (feature): accel-ppp: l2tp implementation

3.2.351 2020-03-13

- T1935 (bug): NIC identification and usage problem in Hyper-V environments
- T1821 (bug): “authentication mode radius” has no effect for PPPoE server
- T1622 (default): Add failsafe and back trace to boot config loader

3.2.352 2020-03-11

- T1961 (bug): VXLAN - fails to commit due to non-existent variable, broken MTU
- T2084 (default): conntrack-tools package build error for current/equuleus

3.2.353 2020-03-10

- T1331 (bug): DNS stops working

3.2.354 2020-03-09

- T2111 (feature): VRF add route leaking support
- T2109 (bug): Ping by name broken in VyOS 1.3-rolling-202003080217
- T1416 (default): 2 dhcp server run in failover mode can't sync hostname with each other
- T2065 (bug): VyOS 1.3 Don't set daemon in openvpn-{intf}.conf file
- T31 (feature): Add VRF support

3.2.355 2020-03-08

- T1954 (bug): Having *system login radius* configured causes exponentially long boot times
- T1760 (bug): RADIUS shared secret is not redacted from "show configuration" op mode command

3.2.356 2020-03-07

- T2107 (bug): Wireless interfaces do not work in station mode without security

3.2.357 2020-03-05

- T2074 (bug): VyOS docker container: Does not possible to configure ethernet interface

3.2.358 2020-03-04

- T2098 (bug): Wrong call to cli-shell-api in generated op-mode templates for path completion helper

3.2.359 2020-03-03

- T2095 (bug): Copy command errors out

3.2.360 2020-03-01

- T2082 (bug): WireGuard broken after merging T2057
- T2089 (feature): RADIUS: do not query servers when commit is running started from a non RADIUS user
- T2087 (feature): Add maxfail 0 option to pppoe configuration.
- T2086 (feature): Move sudo session open/close log entries to auth.log

3.2.361 2020-02-29

- T2046 (feature): allowing sub-classes of Interface to redefine how the interface is created
- T2077 (bug): ISO build from crux branch is failing

3.2.362 2020-02-28

- T2083 (default): vyos-build: build-packages fails at mdns-repeater due to wrong branch
- T2080 (default): traffic-policy shaper error when setting bandwidth

3.2.363 2020-02-27

- T2075 (feature): Add support for OpenVPN tls-crypt file option
- T2079 (feature): Update Linux Kernel to v4.19.106
- T2068 (feature): Update Linux Kernel to v4.19.105
- T1703 (default): Macvlan PPPoE support
- T2078 (feature): Kernel: remove unused RAID functions 5,6,10,jbod,dm

3.2.364 2020-02-25

- T1971 (bug): Missing modules in initrd.img for PXE boot
- T2070 (feature): Rewrite (dis-)connect op-mode commands in XML and Python
- T2071 (feature): Add possibility to temporary disable a RADIUS server used for system login

3.2.365 2020-02-23

- T2055 (feature): Remove IPv6 router-advert options for PPPoE
- T1998 (feature): Update FRR to 7.3
- T1318 (feature): PPPoE client CLI redesign

3.2.366 2020-02-22

- T2063 (feature): vyos-salt-minion package is missing from vyos-world

3.2.367 2020-02-20

- T1969 (default): OSPF with WireGuard cause Route Inactive

3.2.368 2020-02-18

- T2034 (default): Removal of interfaces loopback lo removed 127.0.0.1 and ::1

3.2.369 2020-02-17

- T2047 (feature): Update Linux Kernel to v4.19.104
- T2048 (bug): ISO boot failes when wireleass adapter is present

3.2.370 2020-02-16

- T2043 (bug): Bond VLANs can't be extended on the fly
- T2030 (bug): Bond doesn't survive reboot
- T1992 (bug): Adding vlan on a bond resets all BGP connections on same bond
- T1908 (feature): Add zone option for Cloudflare DDNS
- T1246 (bug): VyOS 1.2.0 "openvpn-options" configuration does not allow quotes in values

3.2.371 2020-02-15

- T2042 (bug): Error on reboot after deleting "service snmp" and not "service lldp snmp enable"
- T2041 (bug): Adding non existent bond interface raises exception

3.2.372 2020-02-14

- T2039 (bug): Wrong system type displayed.
- T2040 (bug): vyos-http-api-server should reload Config in all routes

3.2.373 2020-02-13

- T2033 (feature): Drop vyos-replace package
- T1635 (feature): Rewrite interface pseudo-ethernet in new XML/Python style

3.2.374 2020-02-10

- T2024 (feature): Migrate "system login banner" to XML/Python

3.2.375 2020-02-09

- T2022 (feature): When RADIUS config is active, local logins won't work
- T2020 (default): Unable to log in after upgrade to 1.3-rolling-202002080217
- T1931 (bug): Enabling SNMP commit error

3.2.376 2020-02-08

- T1851 (bug): wireguard - changing the pubkey on an existing peer seems to destroy the running config.

3.2.377 2020-02-05

- T1948 (bug): RADIUS login broken in 1.3
- T1990 (feature): Migrate “system login” to XML/Python representation
- T1585 (default): Add letsencrypt/certbot support for ‘service https’

3.2.378 2020-02-04

- T1965 (bug): VyOS-1.3: ping no longer supports specifying interface or source

3.2.379 2020-02-02

- T2011 (feature): Update Linux Kernel to v4.19.101
- T640 (bug): Images no longer work when built without “recommended” packages

3.2.380 2020-02-01

- T2009 (bug): Ethernet Interface always stays down
- T1989 (bug): conf.get_config_dict() throws exception

3.2.381 2020-01-31

- T1768 (bug): PPTP - vyos.config rewrite
- T2002 (bug): VLAN interfaces try to be enabled even if parent interface is A/D

3.2.382 2020-01-30

- T1994 (default): lldpd not bound to specified interfaces - Fix jinja template
- T1896 (enhancement): Remove LLDP-MED civic_based location information
- T1724 (feature): wireguard - add endpoint check in verify()

3.2.383 2020-01-29

- T1392 (bug): Large firewall rulesets cause the system to lose configuration and crash at startup
- T1996 (feature): Update Linux Kernel to 4.19.99
- T1950 (default): Store VyOS configuration syntax version data in JSON file
- T1862 (default): Use regex pattern s+ to split strings on whitespace in Python 3.7
- T1780 (feature): Adding ipsec ike closeaction
- T1755 (bug): Python KeyError exceptions raised with 'show vpn ipsec sa' command under use of certain IPSEC cipher suites.
- T1747 (bug): L2TP breaks after upgrading to VyOS 1.2-rolling-201910180117 [issue report and proposed solution]
- T1664 (bug): Ipoe with bond per vlan don't work
- T1452 (feature): accel-pppoe - add vendor option to shaper
- T1376 (feature): Incorrect DHCP lease counting
- T1341 (default): Adding rate-limiter for pppoe server users
- T1895 (feature): There is not restriction on selection of syslog facility
- T1670 (feature): OpenVPN option for tls-auth

3.2.384 2020-01-26

- T1937 (bug): snmpd throwing a tremendous amount of errors
- T1767 (bug): IPoE - vyos.config rewrite
- T1765 (bug): wireguard - vyos.config rewrite
- T1964 (default): SNMP Script-extensions allows names with spaces, but commit fails

3.2.385 2020-01-25

- T1902 (feature): Add redistribute non main table in bgp
- T1900 (default): Enable SNMP for VRRP.

3.2.386 2020-01-24

- T1975 (bug): OpenVPN tap devices won't come up automatically

3.2.387 2020-01-23

- T1766 (bug): service-pppoe - vyos.config rewrite

3.2.388 2020-01-21

- T1784 (bug): DMVPN with IPSec does not work in HUB mode
- T1977 (bug): webproxy error on fresh install

3.2.389 2020-01-18

- T1830 (feature): 1.3-rolling boots to GRUB prompt post-install on UEFI systems
- T1940 (bug): EFI Fresh Install fails to boot, 4K Sector Drives Fail to boot EFI

3.2.390 2020-01-16

- T1880 (default): “A stop job is running for live-tools - System Support Scripts” hangs, times out when shutting down equuleus live iso

3.2.391 2020-01-15

- T1959 (bug): Error message when adding IPSec VPN
- T1827 (feature): Increase default gc_thresh

3.2.392 2020-01-13

- T1909 (bug): Incorrect behaviour of static routes with overlapping networks

3.2.393 2020-01-09

- T1955 (feature): snmp - cli config val_help missing
- T1813 (bug): error in generated /etc/hosts file

3.2.394 2020-01-08

- T1946 (bug): Recovery ifname for PPTP remote-access

3.2.395 2020-01-03

- T1939 (feature): Provide abstraction for interface “ip” options

3.2.396 2020-01-01

- T1903 (default): Implementation udev predefined interface naming
- T1825 (feature): Improve DHCP configuration error message
- T1779 (bug): Tunnel interfaces aren’t suggested as being available for bridging
- T1430 (default): Add options for custom DHCP client-id and hostname

3.2.397 2019-12-31

- T1654 (bug): sFlow: multiple “sflow server” not work, and “disable-imt” could break configuration
- T1923 (feature): Migrate L2TPv3 interface to XML/Python

3.2.398 2019-12-30

- T1920 (bug): beep: Error: Running under sudo, which is not supported for security reasons.
- T1918 (bug): l2tp / ipsec config broken in latest daily
- T1897 (bug): IPSec - 1.2 to 1.3 migration failed
- T1921 (bug): snmp: VyOS options no longer recognized
- T1922 (feature): Add VXLAN IPv6 support
- T1858 (default): l2tp: Delete deprecated outside-nexthop and add gateway-address
- T1919 (feature): Migrate “system options” to XML/Python representation

3.2.399 2019-12-28

- T1917 (feature): Update WireGuard to Debian release 0.0.20191219-1
- T1916 (feature): Update Linux Kernel to v4.19.91
- T1915 (bug): Remove “system ipv6 blacklist” option
- T1912 (feature): Migrate “system (iplip6)” to XML/Python representation

3.2.400 2019-12-27

- T1910 (bug): Invalid permissions on latest 1.3 rolling ISO images

3.2.401 2019-12-26

- T1794 (bug): Interface description can’t contain a colon
- T1906 (feature): Migrate “system time-zone” configuration to XML/Python

3.2.402 2019-12-23

- T1898 (enhancement): Support multiple IPv4/IPv6 LLDP management addresses
- T1878 (bug): accel-ppp: pppoe single-session option implementation
- T258 (default): Can not configure wan load-balancing on vyos-1.2

3.2.403 2019-12-22

- T393 (enhancement): Migrate vyatta-lldpd to vyos-1x

3.2.404 2019-12-20

- T1892 (default): vyos-build: Do not install recommends in docker image [enhancement]
- T1893 (bug): igmp-proxy: Do not allow adding unknown interface
- T1411 (enhancement): equuleus: buster: vyatta-ravpn: libfreeradius-client2 is missing in buster

3.2.405 2019-12-19

- T1873 (default): DHCP server fails to start due to a change in isc-dhcp-server init scripts
- T1881 (bug): Execute permissions are removed from custom SNMP scripts at commit time

3.2.406 2019-12-18

- T1889 (bug): Error building docker build image
- T1132 (default): Build on Debian Buster

3.2.407 2019-12-17

- T1886 (feature): Update Linux Kernel to v4.19.89
- T1887 (feature): Update WireGuard to Debian release 0.0.20191212-1

3.2.408 2019-12-15

- T1879 (bug): Extend Dynamic DNS XML definition value help strings and validators

3.2.409 2019-12-13

- T1861 (default): hosts lost after modified static-host-mapping

3.2.410 2019-12-12

- T1864 (feature): Lower IPSec DPD timeout lower limit from 10s -> 2s

3.2.411 2019-12-10

- T1843 (feature): Add GCC preprocessor support for XML files
- T1017 (bug): 1.2.0-rc7 duplex auto (autogenerated config) setting not accepted

3.2.412 2019-12-08

- T1566 (feature): Extend L2TP/IPSec server with IPv6

3.2.413 2019-12-07

- T1714 (bug): Disable DHCP Nameservers Not Working

3.2.414 2019-12-06

- T1860 (feature): Update WireGuard to Debian release 0.0.20191127-2
- T1859 (feature): Update Linux Kernel to v4.19.88
- T1854 (bug): Dynamic DNS configuration cannot be deleted
- T1568 (default): strip-private command improvement for additional masking of IPv6 and MAC address
- T1849 (bug): DHCPv6 client does not start
- T1169 (bug): LLDP potentially broken
- T586 (bug): Cannot add ethernet vif-s vif-c interface to bridge-group

3.2.415 2019-12-05

- T1847 (bug): set_level incorrectly handles path given as empty string

3.2.416 2019-12-04

- T1787 (default): Failed config migration from V1.2.3 to 1.2-rolling-201911030217
- T1212 (bug): IPSec Tunnel to Cisco ASA drops reliably after 4.2GB transferred
- T1704 (feature): OpenVPN - Add support for ncp-ciphers

3.2.417 2019-12-03

- T1782 (bug): pppoe0: showing as “Coming up”
- T1801 (bug): Unescaped backslashes in config values cause configuration failure

3.2.418 2019-12-02

- T1841 (bug): PPP ipv6-up.d direcotry missing
- T1840 (bug): PPPoE doesn't not rename pppX to pppoeX

3.2.419 2019-11-28

- T1299 (feature): Allow SNMPd to be extended with custom scripts

3.2.420 2019-11-25

- T1824 (bug): Permission denied: '/opt/vyatta/etc/config/vyos-migrate.log'

3.2.421 2019-11-24

- T1673 (bug): vif bridge-group not migrated to bridge member interface
- T1799 (feature): Add support for GENEVE (Generic Network Virtualization Encapsulation)

3.2.422 2019-11-23

- T1812 (bug): DHCP: hostnames of clients not resolving after update v1.2.3 -> 1.2-rolling
- T1627 (feature): Rewrite wireless interface in new style XML syntax
- T1811 (bug): Upgrade from 1.1.8: Config file migration failed: module=l2tp

3.2.423 2019-11-22

- T1786 (bug): disable-dhcp-nameservers is missed in current host_name.py implementation
- T1749 (bug): numeric validator doesn't support multiple ranges
- T1701 (bug): Delete domain-name and domain-search won't work
- T1694 (default): NTPd: Do not listen on all interfaces by default
- T1678 (bug): hostfile-update missing line feed
- T1593 (feature): Support ip6gre
- T1391 (feature): In route-map set community additive
- T1772 (bug): <regex> constraints in XML are partially broken
- T1597 (bug): /usr/sbin/rsyslogd after deleting "system syslog"

3.2.424 2019-11-21

- T1818 (default): Print name of migration script on failure
- T1814 (default): Add log of migration scripts run during config migration

3.2.425 2019-11-19

- T1705 (default): High CPU usage by bgpd when snmp is active

3.2.426 2019-11-17

- T1742 (default): NHRP unable to commit.
- T1740 (default): Broken OSPFv2 virtual-link authentication
- T1485 (bug): Enable 'AdvIntervalOpt' option in for radvd.conf
- T1470 (enhancement): improve output of "show dhcpv6 server leases"
- T1421 (bug): OpenVPN client push-route stopped working, needs added quotes to fix
- T1183 (feature): BFD Support via FRR
- T1578 (bug): completion offers "show table", but show table does not exist

- T1401 (bug): Copying files with the FTP protocol fails if the password contains special characters
- T1351 (feature): accel-pppoe adding CIDR based IP pool option

3.2.427 2019-11-16

- T1788 (feature): Intel QAT (QuickAssist Technology) implementation

3.2.428 2019-11-14

- T1710 (default): [equuleus] buster: add patch to fix live-build missing key error
- T1804 (default): Add python3-psutil to docker image
- T1736 (default): Decide on best practice for patching live-team packages for VyOS build system
- T1424 (default): Rewrite the config load script

3.2.429 2019-11-12

- T1800 (feature): Update Linux Kernel to v4.19.84

3.2.430 2019-11-11

- T1793 (feature): Editing description on an interface causes BGP sessions to reset on commit

3.2.431 2019-11-10

- T1598 (default): New implementation of the resolv.conf and hosts update mechanism
- T1792 (feature): Update WireGuard to Debian release 0.0.20191012-1
- T1791 (feature): Update Linux Kernel to 4.19.82

3.2.432 2019-11-09

- T1030 (bug): Upgrade ddclient from 3.8.2 to 3.9.0 (support Cloudflare API v4)

3.2.433 2019-11-08

- T1789 (bug): ddclient not working with generated RFC2136 / nsupdate config

3.2.434 2019-11-03

- T1777 (bug): Bonding interface MAC address mismatch after reboot
- T1752 (bug): PPPoE does not automatically start on boot

3.2.435 2019-11-02

- T1783 (bug): Interface can't unpin from bridge

3.2.436 2019-10-30

- T1778 (bug): Kilobits/Megabits difference in configuration Vyos/FRR

3.2.437 2019-10-28

- T1769 (feature): Remove complex SNMPv3 Transport Security Model (TSM)
- T1738 (bug): Copy SNMP configuration from node to node raises exception
- T818 (feature): SNMP v3 - remove required engineid from user node

3.2.438 2019-10-26

- T1560 (default): "set load-balancing wan rule 0" causes segfault and prevents load balancing from starting

3.2.439 2019-10-22

- T1756 (feature): Modify output to be more useful - Wireguard

3.2.440 2019-10-21

- T1741 (feature): Add system wide proxy setting

3.2.441 2019-10-19

- T1746 (bug): 201910180117 fails startup with 'Permission Denied' errors
- T1745 (default): dhcp-server commit fails with "DHCP range stop address x must be greater or equal to the range start address y!" when static mapping has same IP as range stop
- T1743 (default): equuleus: remove references to SSH key type "rsa1" deprecated in Debian Buster

3.2.442 2019-10-18

- T1712 (default): DHCP client sometimes doesn't start
- T1684 (bug): Unable to enable IPv6 autoconf on PPPoE
- T1604 (enhancement): equuleus: buster: vbash: tab completion breaks

3.2.443 2019-10-17

- T1737 (bug): SNMP tab completion missing

3.2.444 2019-10-14

- T1726 (bug): Update Linux Firmware binaries to a more recent version 2019-03-14 -> 2019-10-07
- T1716 (feature): Update Intel NIC drivers to recent versions

3.2.445 2019-10-13

- T1728 (feature): Update Linux Kernel to 4.19.79

3.2.446 2019-10-11

- T1723 (bug): wireguard - Interface wg01 could not be brought up in time

3.2.447 2019-10-09

- T1719 (feature): ssh deprecated options
- T1718 (bug): ISO check in /opt/vyatta/sbin/install-image faulty
- T1682 (feature): Migrate to new Jenkins Pipeline script

3.2.448 2019-10-08

- T1717 (bug): disable multiple daemons to autostart at boot

3.2.449 2019-10-06

- T1713 (feature): Remove deprecated packages no longer required after migration to Accel-PPP
- T1709 (bug): Update WireGuard to 0.0.20190913
- T1708 (bug): Update Rolling Release Kernel to 4.19.76

3.2.450 2019-10-04

- T1707 (bug): DHCP static mapping and exclude address not working
- T1496 (bug): Separate rolling release and LTS kernel builds

3.2.451 2019-10-03

- T1689 (feature): “reset openvpn” op-mode command should terminate and restart OpenVPN process

3.2.452 2019-10-01

- T1706 (bug): wireguard broken in latest rolling

3.2.453 2019-09-30

- T1642 (bug): BGP configuration error when using remove-private-as
- T1688 (feature): OpenVPN - Add new cipher aes-(128|192|256)-gcm

3.2.454 2019-09-28

- T1696 (bug): NTP - Tests fail when building vyos-lx
- T1512 (bug): vyos 1.2 openvpn client names with spaces created incorrectly

3.2.455 2019-09-27

- T1681 (feature): cleanup wireguard code since tagnodes are now visible
- T1695 (bug): Syntax error in interface-dummy.py

3.2.456 2019-09-26

- T1692 (bug): ipoe-server verify function error
- T1691 (bug): OpenVPN - Committing config when OpenVPN peer/server not available makes commit hang
- T1690 (feature): restart op-mode commands for 'service (pppoe|ipoe)-server'

3.2.457 2019-09-25

- T1672 (bug): Wireguard keys not automatically moved

3.2.458 2019-09-23

- T1679 (bug): during bootup: invalid literal for int() with base 10
- T1680 (feature): DHCP client does not release IP address on exit/deletion

3.2.459 2019-09-21

- T1676 (default): [equuleus] buster: update GRUB boot parameters during upgrade
- T1637 (feature): Rewrite ethernet interface in new style XML syntax
- T1675 (feature): OpenVPN - Specify minimum TLS version

3.2.460 2019-09-20

- T1602 (default): equuleus: buster: add live build apt options for choosing vyos packages

3.2.461 2019-09-19

- T1666 (feature): Deleting a bond will place member interfaces into A/D state

3.2.462 2019-09-17

- T239 (bug): firewall all-ping setting is confusing

3.2.463 2019-09-16

- T1040 (default): rc.local is executed too early

3.2.464 2019-09-15

- T1662 (default): openvpn: 'show openvpn client' error
- T1661 (default): openvpn: wrong checking for existence cert files
- T1630 (bug): OpenVPN after changing it from root to nobody (unprivileged user) cant add routes

3.2.465 2019-09-13

- T1660 (bug): Bonding dont't work on VyOS 1.2-rolling-201909120338
- T1655 (enhancement): equuleus: buster: arm: vyos-accel-ppp build failes because of filename hardcoded as x86_64 in debian/rules

3.2.466 2019-09-12

- T1572 (feature): Wireguard keyPair per interface
- T1545 (bug): IPSEC vti issue

3.2.467 2019-09-10

- T1650 (feature): implement wireguard default key removal
- T1649 (feature): feature documentation different keypairs per interface
- T1648 (feature): add cli command 'delete wireguard named-key <key>'

3.2.468 2019-09-09

- T1639 (bug): wireguard pubkey change error

3.2.469 2019-09-07

- T1640 (feature): Update Linux Kernel to v4.19.70

3.2.470 2019-09-06

- T1624 (bug): Failed to set up config session
- T1636 (feature): Rewrite VXLAN in new style XML/Python
- T1623 (default): Systemd reports dependency cycle during boot
- T1479 (bug): libvyosconfig error reporting doesn't include line numbers
- T808 (feature): replace lighthttpd with nginx
- T1616 (bug): 'renew dhcpv6 interface <interfaceName>' command fails, but work within config session
- T1478 (bug): libvyosconfig parser does not support escaped quotes inside single-quoted strings
- T1360 (bug): DNS nameservers from dhcp not set

3.2.471 2019-09-05

- T1443 (default): New "service https" implementation

3.2.472 2019-09-04

- T1632 (bug): OpenVPN 'push' options with quotes
- T1631 (bug): Multiple push-route options cause error generating openvpn configuration
- T1605 (bug): L2tp over IPsec not working in Crux
- T1557 (feature): Create generic abstraction for configuring interfaces e.g. IP address
- T1439 (bug): DHCPv6 static-mappings not working due to excess quotes around dhcp6.client-id
- T1628 (feature): Adopt WireGuard configuration script to new vyos.ifconfig class
- T1543 (enhancement): Add a source address/interface option for commit archive connections
- T1614 (feature): Rewrite bonding interface in new style XML syntax

3.2.473 2019-09-02

- T1621 (default): Rewrite the rest of trivial vyatta-op commands to new syntax

3.2.474 2019-08-31

- T1559 (default): webproxy (squidguard) doesn't work
- T1531 (bug): Several bugs in cluster configuration
- T1530 (bug): vyos 1.2.1 "set system syslog global archive file" don't work
- T1529 (bug): BGP unnumbered is not working with a vif interface
- T1472 (bug): Impossible to recreate group in rfc3768-compatibility mode
- T1468 (bug): BGP route-reflector-client config erroneously claims remote-as is incorrect
- T1460 (bug): "show firewall ..." doesn't support counters with more than eight digits
- T1456 (bug): Port group cannot be configured if the same port is configured as standalone and inside a range

- T1450 (default): crux: ping * flood is not working
- T1428 (default): Wireguard: fwmark setting is not honored
- T1420 (bug): logrotate permission errors on vyatta logfiles
- T1362 (bug): Incorrect handling of special characters in VRRP passwords

3.2.475 2019-08-30

- T1587 (bug): New implementation of “monitor interface”

3.2.476 2019-08-29

- T1571 (bug): *show log vpn ipsec* produces no output

3.2.477 2019-08-28

- T1615 (feature): After migration to pyroute2 the address DHCP statement is no longer covered

3.2.478 2019-08-27

- T1613 (bug): IPv6 traffic is not captured by NetFlow sensor (pmacct/NFLOG)
- T1617 (default): OpenVPN push route failure
- T1250 (bug): FRR not setting default gateway from dhcp

3.2.479 2019-08-26

- T1591 (bug): OpenVPN “run show openvpn client status” does not work
- T1608 (feature): bridge: Bridge adding non existing interfaces is allowed but does not work
- T1548 (feature): Rewrite OpenVPN interface/op-commands in new style XML/Python
- T1607 (default): Convert ‘reset conntrack’ and ‘reset ip[v6] cache’ operations from vyatta-op to new syntax

3.2.480 2019-08-25

- T1611 (default): Migration to latest rolling fails with vyos.configtree.ConfigTreeError: Path [b’interfaces bridge br0 igmp-snooping querier’] doesn’t exist
- T1333 (bug): pdns_recursor does not perform recursive lookups on domain specific forwarders
- T1524 (feature): Add support to set allow-from network in DNS forwarding

3.2.481 2019-08-23

- T1606 (bug): Rolling release no longer boots after adding hostname daemon

3.2.482 2019-08-22

- T1131 (bug): open-vm-tools causing 100% CPU load

3.2.483 2019-08-21

- T1601 (feature): Rewrite loopback interface type with new style XML/Python interface
- T1596 (default): Convert ‘telnet’ and ‘traceroute’ vyatta-op commands to new syntax

3.2.484 2019-08-20

- T1595 (feature): Migrate deprecated “service dns forwarding listen-on” to listen-address

3.2.485 2019-08-19

- T1580 (feature): Rewrite dummy interface type with new style XML/Python interface
- T1590 (default): Convert ‘show system’ operations from vyatta-op to python/xml syntax
- T1377 (default): BGP Weight Not properly applying

3.2.486 2019-08-17

- T1592 (feature): Update Linux Kernel to v4.19.67
- T1551 (default): Error when creating QinQ interface without earlier sets firewall name, if it used

3.2.487 2019-08-15

- T1584 (default): equuleus: buster: add consistent grub options for predictable interface names

3.2.488 2019-08-13

- T1556 (feature): Rewrite Bridge in new style XML syntax

3.2.489 2019-08-09

- T1569 (feature): interfaceconfig class documetation

3.2.490 2019-08-05

- T1562 (feature): Change version scheme on current branch used for rolling releases

3.2.491 2019-08-04

- T1561 (bug): VyOS rolling ISO cluttered with vyatta-ravpn Git Repo

3.2.492 2019-08-03

- T1554 (bug): Enable RSS (Receive Side Scaling) and Multiqueue for Intel drivers

3.2.493 2019-08-02

- T853 (feature): accel-ppp: SSTP implementation
- T742 (feature): Implement accel-ppp in VyOS

3.2.494 2019-08-01

- T1544 (feature): L2TP documentation

3.2.495 2019-07-31

- T1552 (feature): accel-ppp: SSTP documentation
- T1553 (default): equuleus: buster: add 'noautologin' to boot parameters

3.2.496 2019-07-29

- T1532 (default): [equuleus] buster: GPG error on vyos package repository

3.2.497 2019-07-28

- T1547 (feature): accel-ppp/L2TP restructure CLI
- T1546 (bug): accel-ppp/L2TP radius-source address is not honored

3.2.498 2019-07-23

- T1533 (bug): Rolling builds broken!
- T1489 (feature): Add vlan_mon usage at Accel

3.2.499 2019-07-22

- T1435 (enhancement): Make ip-address [OPTIONAL] (in dhcp-server -> static-mapping) to cope with “unfriendly” client-hostnames of IoT-Devices

3.2.500 2019-07-21

- T823 (feature): Rewrite DHCP op mode in the new style

3.2.501 2019-07-18

- T1497 (bug): “set system name-server” generates invalid/incorrect resolv.conf
- T533 (feature): PPPoE MTU greater than 1492

3.2.502 2019-07-15

- T1526 (feature): [SNMP] write documentation for snmp script extension
- T1516 (bug): [wireguard] config changes cause an error

3.2.503 2019-07-14

- T1066 (bug): Missing NICs

3.2.504 2019-07-10

- T1505 (bug): vyos.config return_effective_values does not convert the output to a list
- T1503 (feature): Add functions for commit lock checking
- T1504 (bug): DHCP-provided DNS servers are not propagated to resolv.conf
- T1400 (bug): iBGP: remote-as and router AS can't be the same value

3.2.505 2019-07-08

- T1465 (bug): Priority inversion in “interfaces vti vtiX ip”
- T1510 (feature): [IPoE] vlan-mon option implementation
- T1508 (feature): [pppoe] migration script for service pppoe-server interface
- T1494 (feature): accel-ppp: IPoE update documentation
- T989 (feature): accel-ppp: IPoE implementation

3.2.506 2019-07-03

- T1502 (feature): Add build sanity checking tools to the dev builds
- T1469 (enhancement): Create forward-zones-recurse entry instead of forward-zones when setting service dns forwarding

3.2.507 2019-07-02

- T1099 (default): Openvpn: use config files instead of one long command.
- T1495 (feature): accel-ppp: IPoE implement IPv6 PD

3.2.508 2019-07-01

- T1498 (bug): Nameservers are not propagated into resolv.conf

3.2.509 2019-06-24

- T1482 (feature): Add OpenVPN SHA384 hashing algorithm
- T1484 (bug): OSPF md5 key not removed in strip-private

3.2.510 2019-06-23

- T1477 (feature): Intel i40evf fails to load - unknown symbol
- T1474 (feature): Update WireGuard to 0.0.20190601
- T1473 (feature): Update Kernel from 4.19.52 to 4.19.54
- T1476 (bug): Update PowerDNS recursor to 4.2 series
- T1475 (feature): Enable Kernel Data Center Bridging (CONFIG_DCB) support
- T1471 (bug): Wireguard interfaces have no firewall subtree
- T1455 (feature): Update Intel i40e driver to 2.9.21
- T1464 (feature): FRR: Set explicit OSPFv3 network type for specified interface

3.2.511 2019-06-22

- T1371 (bug): Arguments of VRRP health check scripts are ignored
- T1313 (feature): Add support for reusable build flavours
- T1202 (bug): Add *hvinfo* to the packages directory
- T1433 (bug): “show dhcpv6 server leases” shows leases from wrong file

3.2.512 2019-06-20

- T1461 (bug): Deleting ‘firewall options’ causes Python TypeError
- T1413 (enhancement): equuleus: buster: vyos-xe-guest-utilities is not installable and breaks live-build
- T1412 (enhancement): equuleus: buster: vyos-netplug is not installable and breaks live-build

3.2.513 2019-06-19

- T1453 (bug): Warning: nss-myhostname is not installed
- T1447 (bug): Python subprocess called without import in host_name.py
- T1334 (feature): Migration script runner rewrite
- T1327 (bug): Set the serial console speed to 115200 by default
- T1454 (bug): Reading deprecated /etc/frr/daemons.conf

3.2.514 2019-06-18

- T1451 (bug): Intel e1000e driver missing in latest rolling release
- T1446 (default): Raid install with efi can generate some warning output.
- T1444 (feature): Update Linux Kernel to v4.19.52

3.2.515 2019-06-17

- T1394 (bug): syslog systemd and host_name.py race condition
- T1408 (feature): pppoe-server - implement local-ipv6 for pure IPv6 based deployments
- T1390 (default): Extend bgp config for bestpath as-path multipath-relax

3.2.516 2019-06-16

- T1438 (bug): DMI board/product serial can't be read

3.2.517 2019-06-12

- T1397 (default): Rewrite the config merge script

3.2.518 2019-06-05

- T1426 (default): Update the script that checks conntrack hash-size on reboot

3.2.519 2019-06-04

- T1379 (bug): Deprecated functions in /sbin/dhclient-script

3.2.520 2019-06-03

- T1423 (default): When merging remote config files, create known_hosts file if not present.

3.2.521 2019-06-01

- T1422 (feature): Add a utility for querying values in config files
- T1309 (bug): allow duplicate ip addresses on different interfaces

3.2.522 2019-05-30

- T1419 (bug): Can't delete multiple OSPF passive-interfaces in single commit

3.2.523 2019-05-28

- T1410 (feature): Upgrade Linux Kernel to 4.19.46

3.2.524 2019-05-26

- T1388 (bug): OpenVPN client connections with password and certificate authentication don't work
- T1387 (bug): Disabling a DHCP interface with no address displays an error
- T1404 (feature): Update iproute2 package to 4.19

3.2.525 2019-05-24

- T1407 (bug): pppoe IPv6 PD documentation by practical example

3.2.526 2019-05-23

- T1402 (feature): Update Linux Kernel to 4.19.45

3.2.527 2019-05-22

- T1399 (bug): accel-ppp kernel modules missing in rolling build 20190522
- T1393 (bug): pppoe IPv6 pool doesn't work

3.2.528 2019-05-21

- T592 (bug): lldpcli: unknown command from argument 1: #

3.2.529 2019-05-20

- T1384 (bug): vxlan remote-port

3.2.530 2019-05-16

- T1267 (feature): FRR: Add interface name for static routes
- T1148 (bug): epa2 BGP peers initiate before config is fully loaded, routes leak.

3.2.531 2019-05-13

- T1378 (feature): Embed Git commit ID of vyos-build repo in resulting image

3.2.532 2019-05-12

- T1370 (bug): Webproxy with ldap authentication don't start

3.2.533 2019-05-09

- T1367 (bug): VIF deletion fails inconsistently

3.2.534 2019-05-06

- T1368 (feature): Enable MPLS support in Linux Kernel

3.2.535 2019-05-05

- T1366 (feature): Update Linux Kernel to v4.19.40

3.2.536 2019-05-04

- T1365 (bug): Cannot configure syslog on 1.2.0-rolling+201904260337

3.2.537 2019-04-29

- T1359 (bug): Changing VLAN interface address from DHCP to static is not handled in vyatta-address script
- T1352 (feature): vyos-documentaion: accel-ppoe adding CIDR based IP pool option

3.2.538 2019-04-26

- T1357 (feature): Wrong exit code produced by dhcp-server migration script

3.2.539 2019-04-25

- T1355 (bug): rsyslog stopped after reboot or clean start

3.2.540 2019-04-23

- T1242 (bug): Error when setting 'pppoe 0 ipv6 address autoconf'
- T1345 (feature): Specify RADIUS source IP for system login command
- T41 (feature): Feature Request: Include bgpq3 for BGP policy creation

3.2.541 2019-04-21

- T314 (default): Unable to apply MSS Clamp with VyOS configuration
- T1348 (feature): Upgrade WireGuard to 0.0.20190406-1
- T1347 (feature): Upgrade Linux Kernel to 4.19.36
- T1343 (default): do not remove trailing zeroes from subnets in DHCP static route config
- T1332 (bug): Upgrade ethtool from 3.16 to 4.19

3.2.542 2019-04-20

- T1335 (default): Configuration migration issue from 1.1.8 to latest 1.2.0 regarding DHCP *authoritative enable* statement
- T1336 (default): *system domain-name* statement doesn't allow domain names ending in a dot on latest 1.2.0
- T1344 (feature): Unclutter “system login radius” configuration nodes
- T1245 (default): Cannot Clamp MSS on Transient Bridge Interfaces - Turn On br_netfilter
- T1310 (feature): Replace system prompt with FQDN

3.2.543 2019-04-19

- T1325 (default): GRE tunnel to Cisco router fails in 1.2.0 - works in 1.1.8

3.2.544 2019-04-17

- T14 (enhancement): Provide VMware OVF and OVA

3.2.545 2019-04-16

- T1274 (feature): Update QLogic firmware files
- T1184 (feature): wireguard - extend documentation with the show interface wireguard commands

3.2.546 2019-04-15

- T1260 (feature): VICI-based implementation of “run show vpn ipsec sa”
- T1273 (default): Add script profiling functionality to the config backend
- T1248 (default): Add a function for copying nodes to the vyos.configtree library

3.2.547 2019-04-10

- T1329 (default): support installation on SD cards fix

3.2.548 2019-04-07

- T1296 (default): Image install can't install to SD cards (mmcblk...)

3.2.549 2019-04-05

- T1324 (feature): update documtation for ‘set system login user level’
- T1322 (bug): Wrong configuration generated for DHCPv6 Relay

3.2.550 2019-04-04

- [T1323](#) (feature): migrate operator accounts to admin accounts and remove the option to setup an operator account

3.2.551 2019-03-26

- [T1312](#) (feature): Allow many to many NAT rules with networks of different size
- [T1305](#) (bug): libvyosconfig parser doesn't work when config lacks a version comment and ends at a leaf node

3.2.552 2019-03-22

- [T1308](#) (bug): Use of '<' in PPPoE password fails
- [T1279](#) (bug): ACPI power event don't work

3.2.553 2019-03-20

- [T1282](#) (feature): Configure VyOS to send syslog messages to remote syslog using fully-qualified domain name
- [T1004](#) (feature): ISO + System Boot with Serial Console for APU2 and Embedded Devices
- [T405](#) (feature): Add binaries for lcdproc

3.2.554 2019-03-17

- [T1218](#) (bug): Static routes not being applied in 1.2 Release
- [T1067](#) (feature): VXLAN support improvements
- [T1285](#) (bug): Kernel issues with 1.2.0 & 1.2.0-rolling+201903060337 causing lockup
- [T1252](#) (feature): Extend vyos-ci Kernel Pipeline to build Intel native drivers
- [T1240](#) (feature): Wireguard module update to 0.0.20190123
- [T484](#) (bug): Rules can't be deleted from firewall rule sets used in zone policies
- [T986](#) (feature): Please update the i40e driver

3.2.555 2019-03-16

- [T1272](#) (bug): VRRP is using physical rather than virtual MAC in RFC-compliant mode

3.2.556 2019-03-12

- [T1284](#) (feature): accel-ppp: pptp implementation documentation
- [T833](#) (feature): accel-ppp: pptp implementation

3.2.557 2019-03-08

- T1277 (bug): Source build of VyOS 1.2.0 (crux) FileNotFoundError exception in show_dhcp.py

3.2.558 2019-03-02

- T929 (bug): Replace Debian firmware packages with upstream Kernel

3.2.559 2019-02-25

- T1261 (default): TFTP-Server only listen on 127.0.0.1
- T1211 (default): Blank hostnames from dhcpd are able to bring down DNS
- T1247 (bug): WAN load-balancing fail when !<x.x.x.x/x> configured in rules
- T1234 (bug): DHCP relay relay-agents-packets is dysfunctional

3.2.560 2019-02-22

- T1257 (bug): implement 'set system static-host-mapping' in host_name.py and remove old function calls

3.2.561 2019-02-21

- T1214 (bug): Add *ipaddrcheck* to the packages directory
- T1255 (bug): /usr/libexec/vyos/conf_mode/host_name.py needs to add an additional newline char

3.2.562 2019-02-19

- T1051 (default): Update openvpn to support TLS 1.2

3.2.563 2019-02-16

- T1174 (bug): "system domain-name" is not reflected in /etc/resolv.conf

3.2.564 2019-02-10

- T1154 (default): use of local cache to build iso

3.2.565 2019-02-09

- T1239 (feature): make module build for vyos-accel-ppp dynamic
- T1236 (feature): Update Linux Kernel to 4.19.20
- T1238 (bug): Wireguard allows invalid IP's
- T1010 (bug): improper pid file handling of webgui

3.2.566 2019-02-08

- [T173](#) (bug): Static routes ignored with DHCP received gateway

3.2.567 2019-02-05

- [T1231](#) (feature): Remove “service dns dynamic” cache file on node change/delete

3.2.568 2019-01-29

- [T166](#) (bug): NPTv6 is broken

3.2.569 2018-12-07

- [T1060](#) (default): Add an option to exclude addresses from transparent wev proxying

3.2.570 2018-04-03

- [T477](#) (bug): Strongswan issue #1220 (packet loss on AWS)

3.3 1.2.6-S1

1.2.6-S1 is a security release release made in September 2020.

3.3.1 Resolved issues

VyOS 1.2.6 release was found to be susceptible to CVE-2020-10995. It’s a low- impact vulnerability in the PowerDNS recursor that allows an attacker to cause performance degradation via a specially crafted authoritative DNS server reply.

- [T2899](#) remote syslog server migration error on update

3.4 1.2.6

1.2.6 is a maintenance release made in September 2020.

3.4.1 Resolved issues

- [T103](#) DHCP server prepends shared network name to hostnames
- [T125](#) Missing PPPoE interfaces in l2tp configuration
- [T1194](#) cronjob is being setup even if not saved
- [T1205](#) module pcspkr missing
- [T1219](#) Redundant active-active configuration, asymmetric routing and conntrack-sync cache
- [T1220](#) Show transceiver information from plugin modules, e.g SFP+, QSFP

- T1221 BGP - Default route injection is not processed by the specific route-map
- T1241 Remove of policy route throws CLI error
- T1291 Under certain conditions the VTI will stay forever down
- T1463 Missing command *show ip bgp scan* appears in command completion
- T1575 *show snmp mib ifmib* crashes with IndexError
- T1699 Default `net.ipv6.route.max_size` 32768 is too low
- T1729 PIM (Protocol Independent Multicast) implementation
- T1901 Semicolon in values is interpreted as a part of the shell command by validators
- T1934 Change default hostname when deploy from OVA without params.
- T1938 syslog doesn't start automatically
- T1949 Multihop IPv6 BFD is unconfigurable
- T1953 DDNS service name validation rejects valid service names
- T1956 PPPoE server: support PADO-delay
- T1973 Allow route-map to match on BGP local preference value
- T1974 Allow route-map to set administrative distance
- T1982 Increase rotation for `atop.acct`
- T1983 Expose route-map when BGP routes are programmed in to FIB
- T1985 pppoe: Enable ipv6 modules without configured ipv6 pools
- T2000 strongSwan does not install routes to table 220 in certain cases
- T2021 OSPFv3 doesn't support decimal area syntax
- T2062 Wrong dhcp-server static route subnet bytes
- T2091 `swanctl.conf` file is not generated properly is more than one IPsec profile is used
- T2131 Improve syslog remote host CLI definition
- T2224 Update Linux Kernel to v4.19.114
- T2286 IPoE server vulnerability
- T2303 Unable to delete the image version that came from OVA
- T2305 Add release name to "show version" command
- T2311 Statically configured name servers may not take precedence over ones from DHCP
- T2327 Unable to create syslog server entry with different port
- T2332 Backport node option for a syslog server
- T2342 Bridge l2tpv3 + ethX errors
- T2344 PPPoE server client static IP assignment silently fails
- T2385 salt-minion: improve completion helpers
- T2389 BGP community-list unknown command
- T2398 op-mode "dhcp client leases interface" completion helper misses interfaces
- T2402 Live ISO should warn when configuring that changes won't persist

- T2443 NHRP: Add debugging information to syslog
- T2448 *monitor protocol bgp* subcommands fail with ‘command incomplete’
- T2458 Update FRR to 7.3.1
- T2476 Bond member description change leads to network outage
- T2478 login radius: use NAS-IP-Address if defined source address
- T2482 Update PowerDNS recursor to 4.3.1 for CVE-2020-10995
- T2517 vyos-container: link_filter: No such file or directory
- T2526 Wake-On-Lan CLI implementation
- T2528 “update dns dynamic” throws FileNotFoundError excepton
- T2536 “show log dns forwarding” still refers to dnsmasq
- T2538 Update Intel NIC drivers to recent release (preparation for Kernel >=5.4)
- T2545 Show physical device offloading capabilities for specified ethernet interface
- T2563 Wrong interface binding for Dell VEP 1445
- T2605 SNMP service is not disabled by default
- T2625 Provide generic Library for package builds
- T2686 FRR: BGP: large-community configuration is not applied properly after upgrading FRR to 7.3.x series
- T2701 *vpn ipsec pfs enable* doesn’t work with IKE groups
- T2728 Protocol option ignored for IPSec peers in transport mode
- T2734 WireGuard: fwmark CLI definition is inconsistent
- T2757 “show system image version” contains additional new-line character breaking output
- T2797 Update Linux Kernel to v4.19.139
- T2822 Update Linux Kernel to v4.19.141
- T2829 PPPoE server: mppe setting is implemented as node instead of leafNode
- T2831 Update Linux Kernel to v4.19.142
- T2852 rename dynamic dns interface breaks ddclient.cache permissions
- T2853 Intel QAT acceleration does not work

3.5 1.2.5

1.2.5 is a maintenance release made in April 2020.

3.5.1 Resolved issues

- T1020 OSPF Stops distributing default route after a while
- T1228 pppoe default-route force option not working (Rel 1.2.0-rc11)
- T1301 bgp peer-groups don’t work when “no-ipv4-unicast” is enabled.
- T1341 Adding rate-limiter for pppoe server users

- T1376 Incorrect DHCP lease counting
- T1392 Large firewall rulesets cause the system to lose configuration and crash at startup
- T1416 2 dhcp server run in failover mode can't sync hostname with each other
- T1452 accel-pppoe - add vendor option to shaper
- T1490 BGP configuration (is lost/not applied) when updating 1.1.8 -> 1.2.1
- T1780 Adding ipsec ike closeaction
- T1803 Unbind NTP while it's not requested...
- T1821 "authentication mode radius" has no effect for PPPoE server
- T1827 Increase default gc_thresh
- T1828 Missing completion helper for "set system syslog host 192.0.2.1 facility all protocol"
- T1832 radvd adding feature DNSSL branch.example.com example.com to existing package
- T1837 PPPoE unrecognized option 'replacedefaultroute'
- T1851 wireguard - changing the pubkey on an existing peer seems to destroy the running config.
- T1858 l2tp: Delete deprecated outside-nexthop and add gateway-address
- T1864 Lower IPsec DPD timeout lower limit from 10s -> 2s
- T1879 Extend Dynamic DNS XML definition value help strings and validators
- T1881 Execute permissions are removed from custom SNMP scripts at commit time
- T1884 Keeping VRRP transition-script native behaviour and adding stop-script
- T1891 Router announcements broken on boot
- T1900 Enable SNMP for VRRP.
- T1902 Add redistribute non main table in bgp
- T1909 Incorrect behaviour of static routes with overlapping networks
- T1913 "system ipv6 blacklist" command has no effect
- T1914 IPv6 multipath hash policy does not apply
- T1917 Update WireGuard to Debian release 0.0.20191219-1
- T1934 Change default hostname when deploy from OVA without params.
- T1935 NIC identification and usage problem in Hyper-V environments
- T1936 pppoe-server CLI control features
- T1964 SNMP Script-extensions allows names with spaces, but commit fails
- T1967 BGP parameter "enforce-first-as" does not work anymore
- T1970 Correct adding interfaces on boot
- T1971 Missing modules in initrd.img for PXE boot
- T1998 Update FRR to 7.3
- T2001 Error when router reboot
- T2032 Monitor bandwidth bits
- T2059 Set source-validation on bond vif don't work

- T2066 PPPoE interface can be created multiple times - last wins
- T2069 PPPoE-client does not works with service-name option
- T2077 ISO build from crux branch is failing
- T2079 Update Linux Kernel to v4.19.106
- T2087 Add maxfail 0 option to pppoe configuration.
- T2100 BGP route advertisement wih checks rib
- T2120 “reset vpn ipsec-peer” doesn’t work with named peers
- T2197 Cant add vif-s interface into a bridge
- T2228 WireGuard does not allow ports < 1024 to be used
- T2252 HTTP API add system image can return ‘504 Gateway Time-out’
- T2272 Set system flow-accounting disable-imt has syntax error
- T2276 PPPoE server vulnerability

3.6 1.2.4

1.2.4 is a maintenance release made in December 2019.

3.6.1 Resolved issues

- T258 Can not configure wan load-balancing on vyos-1.2
- T818 SNMP v3 - remove required engineid from user node
- T1030 Upgrade ddclient from 3.8.2 to 3.9. (support Cloudflare API v4)
- T1183 BFD Support via FRR
- T1299 Allow SNMPd to be extended with custom scripts
- T1351 accel-pppoe adding CIDR based IP pool option
- T1391 In route-map set community additive
- T1394 syslog systemd and host_name.py race condition
- T1401 Copying files with the FTP protocol fails if the passwor contains special characters
- T1421 OpenVPN client push-route stopped working, needs added quotes to fix
- T1430 Add options for custom DHCP client-id and hostname
- T1447 Python subprocess called without import in host_name.py
- T1470 improve output of “show dhcpv6 server leases”
- T1485 Enable ‘AdvIntervalOpt’ option in for radvd.conf
- T1496 Separate rolling release and LTS kernel builds
- T1560 “set load-balancing wan rule 0” causes segfault and prevent load balancing from starting
- T1568 strip-private command improvement for additional masking o IPv6 and MAC address
- T1578 completion offers “show table”, but show table does not exist

- T1593 Support ip6gre
- T1597 /usr/sbin/rsyslogd after deleting “system syslog”
- T1638 vyos-hostsd not setting system domain name
- T1678 hostfile-update missing line feed
- T1694 NTPd: Do not listen on all interfaces by default
- T1701 Delete domain-name and domain-search won't work
- T1705 High CPU usage by bgpd when snmp is active
- T1707 DHCP static mapping and exclude address not working
- T1708 Update Rolling Release Kernel to 4.19.76
- T1709 Update WireGuard to 0.0.20190913
- T1716 Update Intel NIC drivers to recent versions
- T1726 Update Linux Firmware binaries to a more recent version 2019-03-14 -> 2019-10-07
- T1728 Update Linux Kernel to 4.19.79
- T1737 SNMP tab completion missing
- T1738 Copy SNMP configuration from node to node raises exception
- T1740 Broken OSPFv2 virtual-link authentication
- T1742 NHRP unable to commit.
- T1745 dhcp-server commit fails with “DHCP range stop address must be greater or equal to the range start address y!” when static mapping has same IP as range stop
- T1749 numeric validator doesn't support multiple ranges
- T1769 Remove complex SNMPv3 Transport Security Model (TSM)
- T1772 <regex> constraints in XML are partially broken
- T1778 Kilobits/Megabits difference in configuration Vyos/FRR
- T1780 Adding ipsec ike closeaction
- T1786 disable-dhcp-nameservers is missed in current host_name.p implementation
- T1788 Intel QAT (QuickAssist Technology) implementation
- T1792 Update WireGuard to Debian release 0.0.20191012-1
- T1800 Update Linux Kernel to v4.19.84
- T1809 Wireless: SSID scan does not work in AP mode
- T1811 Upgrade from 1.1.8: Config file migration failed: module=l2tp
- T1812 DHCP: hostnames of clients not resolving after update v1.2.3 -> 1.2-rolling
- T1819 Reboot kills SNMPv3 configuration
- T1822 Priority inversion wireless interface dhcpv6
- T1825 Improve DHCP configuration error message
- T1836 import-conf-mode-commands in vyos-lx/scripts fails to create an xml
- T1839 LLDP shows “VyOS unknown” instead of “VyOS”

- T1841 PPP ipv6-up.d direcotry missing
- T1893 igmp-proxy: Do not allow adding unknown interface
- T1903 Implementation udev predefined interface naming
- T1904 update eth1 and eth2 link files for the vep4600

3.7 1.2.3

1.2.3 is a maintenance and feature backport release made in September 2019.

3.7.1 New features

- HTTP API
- T1524 “set service dns forwarding allow-from <IPv4 net|IPv6 net>” option for limiting queries to specific client networks
- T1503 Functions for checking if a commit is in progress
- T1543 “set system config-mangement commit-archive source-address” option
- T1554 Intel NIC drivers now support receive side scaling and multiqueue

3.7.2 Resolved issues

- T1209 OSPF max-metric values over 100 no longer causes commit errors
- T1333 Fixes issue with DNS forwarding not performing recursive lookups on domain specific forwarders
- T1362 Special characters in VRRP passwords are handled correctly
- T1377 BGP weight is applied properly
- T1420 Fixed permission for log files
- T1425 Wireguard interfaces now support /31 addresses
- T1428 Wireguard correctly handles firewall marks
- T1439 DHCPv6 static mappings now work correctly
- T1450 Flood ping commands now works correctly
- T1460 Op mode “show firewall” commands now support counters longer than 8 digits (T1460)
- T1465 Fixed priority inversion in VTI commands
- T1468 Fixed remote-as check in the BGP route-reflector-client option
- T1472 It’s now possible to re-create VRRP groups with RFC compatibility mode enabled
- T1527 Fixed a typo in DHCPv6 server help strings
- T1529 Unnumbered BGP peers now support VLAN interfaces
- T1530 Fixed “set system syslog global archive file” command
- T1531 Multiple fixes in cluster configuration scripts
- T1537 Fixed missing help text for “service dns”

- [T1541](#) Fixed input validation in DHCPv6 relay options
- [T1551](#) It's now possible to create a QinQ interface and a firewall assigned to it in one commit
- [T1559](#) URL filtering now uses correct rule database path and works again
- [T1579](#) “show log vpn ipsec” command works again
- [T1576](#) “show arp interface <intf>” command works again
- [T1605](#) Fixed regression in L2TP/IPsec server
- [T1613](#) Netflow/sFlow captures IPv6 traffic correctly
- [T1616](#) “renew dhcpv6” command now works from op mode
- [T1642](#) BGP remove-private-as option iBGP vs eBGP check works correctly now
- [T1540](#), [T1360](#), [T1264](#), [T1623](#) Multiple improvements in name servers and hosts configuration handling

3.7.3 Internals

`/etc/resolv.conf` and `/etc/hosts` files are now managed by the `vyos-hostsd` service that listens on a ZMQ socket for update messages.

3.8 1.2.2

1.2.2 is a maintenance release made in July 2019.

3.8.1 New features

- Options for per-interface MSS clamping.
- BGP extended next-hop capability
- Relaxed BGP multipath option
- Internal and external options for “remote-as” (accept any AS as long as it's the same to this router or different, respectively)
- “Unnumbered” (interface-based) BGP peers
- BGP no-prepend option
- Additive BGP community option
- OSPFv3 network type option
- Custom arguments for VRRP scripts
- A script for querying values from config files

3.8.2 Resolved issues

- Linux kernel 4.19.54, including a fix for the TCP SACK vulnerability
- [T1371](#) VRRP health-check scripts now can use arguments
- [T1497](#) DNS server addresses coming from a DHCP server are now correctly propagated to `resolv.conf`

- T1469 Domain-specific name servers in DNS forwarding are now used for recursive queries
- T1433 `run show dhcpv6 server leases` now display leases correctly
- T1461 Deleting `firewall options node` no longer causes errors
- T1458 Correct hostname is sent to remote syslog again
- T1438 Board serial number from DMI is correctly displayed in `show version`
- T1358, T1355, T1294 Multiple corrections in remote syslog config
- T1255 Fixed missing newline in `/etc/hosts`
- T1174 `system domain-name` is correctly included in `/etc/resolv.conf`
- T1465 Fixed priority inversion in `interfaces vti vtiX ip` settings
- T1446 Fixed errors when installing with RAID1 on UEFI machines
- T1387 Fixed an error on disabling an interfaces that has no address
- T1367 Fixed deleting VLAN interface with non-default MTU
- T1505 `vyos.config.return_effective_values()` function now correctly returns a list rather than a string

3.9 1.2.1

VyOS 1.2.1 is a maintenance release made in April 2019.

3.9.1 Resolved issues

- Package updates: kernel 4.19.32, open-vm-tools 10.3, latest Intel NIC drivers
- T1326 The kernel now includes drivers for various USB serial adapters, which allows people to add a serial console to a machine without onboard RS232, or connect to something else from the router
- The collection of network card firmware is now much more extensive
- T1271 VRRP now correctly uses a virtual rather than physical MAC addresses in the RFC-compliant mode
- T1330 DHCP WPAD URL option works correctly again
- T1312 Many to many NAT rules now can use source/destination and translation networks of non-matching size. If 1:1 network bits translation is desired, it's now users responsibility to check if prefix length matches.
- T1290 IPv6 network prefix translation is fixed
- T1308 Non-alphanumeric characters such as `>` can now be safely used in PPPoE passwords
- T1305 `show | commands` no longer fails when a config section ends with a leaf node such as `timezone` in `show system | commands`
- T1235 `show | commands` correctly works in config mode now
- T1298 VTI is now compatible with the DHCP-interface IPsec option
- T1277 `show dhcp server statistics` command was broken in latest Crux
- T1261 An issue with TFTP server refusing to listen on addresses other than loopback was fixed
- T1224 Template issue that might cause UDP broadcast relay fail to start is fixed
- T1067 VXLAN value validation is improved

- T1211 Blank hostnames in DHCP updates no longer can crash DNS forwarding
- T1322 Correct configuration is now generated for DHCPv6 relays with more than one upstream interface
- T1234 `relay-agents-packets` option works correctly now
- T1231 Dynamic DNS data is now cleaned on configuration change
- T1282 Remote Syslog can now use a fully qualified domain name
- T1279 ACPI power off works again
- T1247 Negation in WAN load balancing rules works again
- T1218 FRR staticd now starts on boot correctly
- T1296 The installer now correctly detects SD card devices
- T1225 Wireguard peers can be disabled now
- T1217 The issue with Wireguard interfaces impossible to delete is fixed
- T1160 Unintended IPv6 access is fixed in SNMP configuration
- T1060 It's now possible to exclude hosts from the transparent web proxy
- T484 An issue with rules impossible to delete from the zone-based firewall is fixed

Installation and Image Management

4.1 Installation

VyOS installation requires a downloaded VyOS .iso file. That file is a live install image that lets you boot a live VyOS. From the live system, you can proceed to a permanent installation on a hard drive or any other type of storage.

4.1.1 Hardware requirements

The minimum system requirements are 512 MiB RAM and 2 GiB storage. Depending on your use, you might need additional RAM and CPU resources e.g. when having multiple BGP full tables in your system.

4.1.2 Download

Registered Subscribers

Registered subscribers can log into <https://support.vyos.io/> to access a variety of different downloads via the “Downloads” link. These downloads include LTS (Long-Term-Support), the associated hot-fix releases, early public access releases, pre-built VM images, as well as device specific installation ISOs.

Building from source

Non-subscribers can always get the LTS release by building it from source. Instructions can be found in the *Build VyOS* section of this manual. VyOS source code repository is available for everyone at <https://github.com/vyos/vyos-build>.

Rolling Release

Everyone can download bleeding-edge VyOS rolling images from: <https://downloads.vyos.io/>

VyOS 1.2.2 for VMWare

VyOS 1.2.1 for VMWare

Note: Rolling releases contain all the latest enhancements and fixes. This means that there will be new bugs of course. If you think you hit a bug please follow the guide at [Bug Report/Issue](#). We depend on your feedback to improve vyOS!

The following link will always fetch the most recent VyOS build for AMD64 systems from the current branch: <https://downloads.vyos.io/rolling/current/amd64/vyos-rolling-latest.iso>

Download Verification

LTS images are signed by the VyOS lead package-maintainer private key. With the official public key, the authenticity of the package can be verified. GPG (GNU Privacy Guard) is used for verification.

Note: This subsection only applies to LTS images, for Rolling images please jump to [Live installation](#).

Preparing for the verification

First, install GPG or another OpenPGP implementation. On most GNU+Linux distributions it is installed by default as package managers use it to verify package signatures. If not pre-installed, it will need to be downloaded and installed.

The official VyOS public key can be retrieved in a number of ways. Skip to [GPG verification](#) if the key is already present.

It can be retrieved directly from a key server:

```
gpg --recv-keys FD220285A0FE6D7E
```

Or it can be accessed via a web browser:

<https://pgp.mit.edu/pks/lookup?op=get&search=0xFD220285A0FE6D7E>

Or from the following block:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----
Version: GnuPG v1.4.12 (GNU/Linux)

mQINBFXKsiIBEACyid9PR/v56pSRG8VgQyRwvzoI7rLErZ8BCQA2WFxA6+zNy+6G

-----END PGP PUBLIC KEY BLOCK-----

```

Store the key in a new text file and import it into GPG via: `gpg --import file_with_the_public_key`

The import can be verified with:

```

$ gpg --list-keys
...
pub      rsa4096 2015-08-12 [SC]
         0694A9230F5139BF834BA458FD220285A0FE6D7E
uid          [ unknown] VyOS Maintainers (VyOS Release) <maintainers@vyos.net>

```

(continues on next page)

(continued from previous page)

```
sub    rsa4096 2015-08-12 [E]
```

GPG verification

With the public key imported, the signature for the desired image needs to be downloaded.

Note: The signature can be downloaded by appending `.asc` to the URL of the downloaded VyOS image. That small `.asc` file is the signature for the associated image.

Finally, verify the authenticity of the downloaded image:

```
$ gpg2 --verify vyos-1.2.1-amd64.iso.asc vyos-1.2.1-amd64.iso
gpg: Signature made So 14 Apr 12:58:07 2019 CEST
gpg:                using RSA key FD220285A0FE6D7E
gpg: Good signature from "VyOS Maintainers (VyOS Release) <maintainers@vyos.net>"
→ [unknown]
Primary key fingerprint: 0694 A923 0F51 39BF 834B  A458 FD22 0285 A0FE 6D7E
```

4.1.3 Live installation

Note: A permanent VyOS installation always requires to go first through a live installation.

VyOS, as other GNU+Linux distributions, can be tested without installing it in your hard drive. **With your downloaded VyOS .iso file you can create a bootable USB drive that will let you boot into a fully functional VyOS system.** Once you have tested it, you can either decide to begin a [Permanent installation](#) in your hard drive or power your system off, remove the USB drive, and leave everything as it was.

If you have a GNU+Linux system, you can create your VyOS bootable USB stick with with the `dd` command:

1. Open your terminal emulator.
2. Find out the device name of your USB drive (you can use the `lsblk` command)
3. Unmount the USB drive. Replace X in the example below with the letter of your device and keep the asterisk (wildcard) to unmount all partitions.

```
$ umount /dev/sdX*
```

4. Write the image (your VyOS .iso file) to the USB drive. Note that here you want to use the device name (e.g. `/dev/sdb`), not the partition name (e.g. `/dev/sdb1`).

Warning: This will destroy all data on the USB drive!

```
# dd if=/path/to/vyos.iso of=/dev/sdX bs=8M; sync
```

5. Wait until you get the outcome (bytes copied). Be patient, in some computers it might take more than one minute.
6. Once `dd` has finished, pull the USB drive out and plug it into the powered-off computer where you want to install (or test) VyOS.

7. Power the computer on, making sure it boots from the USB drive (you might need to select booting device or change booting settings).
8. Once VyOS is completely loaded, enter the default credentials (login: vyos, password: vyos).

If you find difficulties with this method, prefer to use a GUI program, or have a different operating system, there are other programs you can use to create a bootable USB drive, like [balenaEtcher](#) (for GNU/Linux, macOS and Windows), [Rufus](#) (for Windows) and [many others](#). You can follow their instructions to create a bootable USB drive from an .iso file.

Hint: The default username and password for the live system is `vyos`.

4.1.4 Permanent installation

Note: Before a permanent installation, VyOS requires a [Live installation](#).

Unlike general purpose Linux distributions, VyOS uses “image installation” that mimics the user experience of traditional hardware routers and allows keeping multiple VyOS versions installed simultaneously. This makes it possible to switch to a previous version if something breaks or miss-behaves after an image upgrade.

Every version is contained in its own squashfs image that is mounted in a union filesystem together with a directory for mutable data such as configurations, keys, or custom scripts.

Note: Older versions (prior to VyOS 1.1) used to support non-image installation (`install system` command). Support for this has been removed from VyOS 1.2 and newer releases. Older releases can still be upgraded via the general `add system image <image_path> upgrade` command (consult [Image Management](#) for further information).

In order to proceed with a permanent installation:

1. Log into the VyOS live system (use the default credentials: `vyos`, `vyos`)
2. Run the `install image` command and follow the wizard:

```
vyos@vyos:~$ install image
Welcome to the VyOS install program. This script
will walk you through the process of installing the
VyOS image to a local hard drive.
Would you like to continue? (Yes/No) [Yes]: Yes
Probing drives: OK
Looking for pre-existing RAID groups...none found.
The VyOS image will require a minimum 2000MB root.
Would you like me to try to partition a drive automatically
or would you rather partition it manually with parted? If
you have already setup your partitions, you may skip this step

Partition (Auto/Parted/Skip) [Auto]:

I found the following drives on your system:
sda      4294MB

Install the image on? [sda]:
```

(continues on next page)

(continued from previous page)

```

This will destroy all data on /dev/sda.
Continue? (Yes/No) [No]: Yes

How big of a root partition should I create? (2000MB - 4294MB) [4294]MB:

Creating filesystem on /dev/sda1: OK
Done!
Mounting /dev/sda1...
What would you like to name this image? [1.2.0-rolling+201809210337]:
OK. This image will be named: 1.2.0-rolling+201809210337
Copying squashfs image...
Copying kernel and initrd images...
Done!
I found the following configuration files:
  /opt/vyatta/etc/config.boot.default
Which one should I copy to sda? [/opt/vyatta/etc/config.boot.default]:

Copying /opt/vyatta/etc/config.boot.default to sda.
Enter password for administrator account
Enter password for user 'vyos':
Retype password for user 'vyos':
I need to install the GRUB boot loader.
I found the following drives on your system:
sda      4294MB

Which drive should GRUB modify the boot partition on? [sda]:

Setting up grub: OK
Done!

```

3. After the installation is completed, remove the live USB stick or CD.

4. Reboot the system.

```

vyos@vyos:~$ reboot
Proceed with reboot? (Yes/No) [No] Yes

```

You will boot now into a permanent VyOS system.

4.1.5 PXE Boot

VyOS can also be installed through PXE. This is a more complex installation method that allows deploying VyOS through the network.

Requirements

- Clients (where VyOS is to be installed) with a PXE-enabled NIC
- *DHCP Server*
- *TFTP Server*
- Webserver (HTTP) - optional, but we will use it to speed up installation
- VyOS ISO image to be installed (do not use images prior to VyOS 1.2.3)
- Files *pxelinux.0* and *ldlinux.c32* from the [Syslinux](#) distribution

Configuration

Step 1: DHCP

Configure a DHCP server to provide the client with:

- An IP address
- The TFTP server address (DHCP option 66). Sometimes referred as *boot server*
- The *bootfile name* (DHCP option 67), which is *pxelinux.0*

In this example we configured an existent VyOS as the DHCP server:

```
vyos@vyos# show service dhcp-server
shared-network-name mydhcp {
    subnet 192.168.1.0/24 {
        bootfile-name pxelinux.0
        bootfile-server 192.168.1.50
        default-router 192.168.1.50
        range 0 {
            start 192.168.1.70
            stop 192.168.1.100
        }
    }
}
```

Step 2: TFTP

Configure a TFTP server so that it serves the following:

- The *pxelinux.0* file from the Syslinux distribution
- The *ldlinux.c32* file from the Syslinux distribution
- The kernel of the VyOS software you want to deploy. That is the *vmlinuz* file inside the */live* directory of the extracted contents from the ISO file.
- The initial ramdisk of the VyOS ISO you want to deploy. That is the *initrd.img* file inside the */live* directory of the extracted contents from the ISO file. Do not use an empty (0 bytes) *initrd.img* file you might find, the correct file may have a longer name.
- A directory named *pxelinux.cfg* which must contain the configuration file. We will use the [configuration](#) file shown below, which we named *default*.

In the example we configured our existent VyOS as the TFTP server too:

```
vyos@vyos# show service tftp-server
directory /config/tftpboot
listen-address 192.168.1.50
```

Example of the contents of the TFTP server:

```
vyos@vyos# ls -hal /config/tftpboot/
total 29M
drwxr-sr-x 3 tftp tftp      4.0K Oct 14 00:23 .
drwxrwsr-x 9 root vyattacfg 4.0K Oct 18 00:05 ..
-r--r--r-- 1 root vyattacfg 25M Oct 13 23:24 initrd.img-4.19.54-amd64-vyos
-rwxr-xr-x 1 root vyattacfg 120K Oct 13 23:44 ldlinux.c32
```

(continues on next page)

(continued from previous page)

```
-rw-r--r-- 1 root vyattacfg 46K Oct 13 23:24 pxelinux.0
drwxr-xr-x 2 root vyattacfg 4.0K Oct 14 01:10 pxelinux.cfg
-r--r--r-- 1 root vyattacfg 3.7M Oct 13 23:24 vmlinuz

vyos@vyos# ls -hal /config/tftpboot/pxelinux.cfg
total 12K
drwxr-xr-x 2 root vyattacfg 4.0K Oct 14 01:10 .
drwxr-sr-x 3 tftp tftp      4.0K Oct 14 00:23 ..
-rw-r--r-- 1 root root      191 Oct 14 01:10 default
```

Example of simple (no menu) configuration file:

```
vyos@vyos# cat /config/tftpboot/pxelinux.cfg/default
DEFAULT VyOS123

LABEL VyOS123
    KERNEL vmlinuz
    APPEND initrd=initrd.img-4.19.54-amd64-vyos boot=live nopersistence noautologin_
↪nonetworking fetch=http://address:8000/filesystem.squashfs
```

Step 3: HTTP

We also need to provide the *filesystem.squashfs* file. That is a heavy file and TFTP is slow, so you could send it through HTTP to speed up the transfer. That is how it is done in our example, you can find that in the configuration file above.

First run a web server - you can use a simple one like [Python's SimpleHTTPServer](#) and start serving the *filesystem.squashfs* file. The file can be found inside the */live* directory of the extracted contents of the ISO file.

Second, edit the configuration file of the [Step 2: TFTP](#) so that it shows the correct URL at `fetch=http://<address_of_your_HTTP_server>/filesystem.squashfs`.

Note: Do not change the name of the *filesystem.squashfs* file. If you are working with different versions, you can create different directories instead.

And **third**, restart the TFTP service. If you are using VyOS as your TFTP Server, you can restart the service with `sudo service tftpd-hpa restart`.

Note: Make sure the available directories and files in both TFTP and HTTP server have the right permissions to be accessed from the booting clients.

Client Boot

Finally, turn on your PXE-enabled client or clients. They will automatically get an IP address from the DHCP server and start booting into VyOS live from the files automatically taken from the TFTP and HTTP servers.

Once finished you will be able to proceed with the `install image` command as in a regular VyOS installation.

4.1.6 Known Issues

This is a list of known issues that can arise during installation.

Black screen on install

GRUB attempts to redirect all output to a serial port for ease of installation on headless hosts. This appears to cause an hard lockup on some hardware that lacks a serial port, with the result being a black screen after selecting the *Live system* option from the installation image.

The workaround is to type *e* when the boot menu appears and edit the GRUB boot options. Specifically, remove the:

```
console=ttyS0,115200
```

option, and type CTRL-X to boot.

Installation can then continue as outlined above.

4.2 Running VyOS in Virtual Environments

4.2.1 Running on Libvirt Qemu/KVM

Libvirt is an open-source API, daemon and management tool for managing platform virtualization. There are several ways to deploy VyOS on libvirt kvm. Use Virt-manager and native CLI. In an example we will be use use 4 gigabytes of memory, 2 cores CPU and default network virbr0.

CLI

Deploy from ISO

Create VM name `vyos_r1`. You must specify the path to the ISO image, the disk `qcow2` will be created automatically. The default network is the virtual network (type Virtio) created by the hypervisor with NAT.

```
$ virt-install -n vyos_r1 \
  --ram 4096 \
  --vcpus 2 \
  --cdrom /var/lib/libvirt/images/vyos.iso \
  --os-type linux \
  --os-variant debian10 \
  --network network=default \
  --graphics vnc \
  --hvm \
  --virt-type kvm \
  --disk path=/var/lib/libvirt/images/vyos_r1.qcow2,bus=virtio,size=8 \
  --noautoconsole
```

Connect to VM with command `virsh console vyos_r1`

```
$ virsh console vyos_r1

Connected to domain vyos_r1
Escape character is ^]

vyos login: vyos
Password:

vyos@vyos:~$ install image
```

After installation - exit from the console using the key combination `Ctrl +]` and reboot the system.

Deploy from qcow2

The convenience of using KVM (Kernel-based Virtual Machine) images is that they don't need to be installed. Download predefined VyOS.qcow2 image for KVM

```
curl --url link_to_vyos_kvm.qcow2 --output /var/lib/libvirt/images/vyos_kvm.qcow2
```

Create VM with import qcow2 disk option.

```
$ virt-install -n vyos_r2 \
  --ram 4096 \
  --vcpus 2 \
  --os-type linux \
  --os-variant debian10 \
  --network network=default \
  --graphics vnc \
  --hvm \
  --virt-type kvm \
  --disk path=/var/lib/libvirt/images/vyos_kvm.qcow2,bus=virtio \
  --import \
  --noautoconsole
```

Connect to VM with command `virsh console vyos_r2`

```
$ virsh console vyos_r2

Connected to domain vyos_r2
Escape character is ^]

vyos login: vyos
Password:

vyos@vyos:~$
```

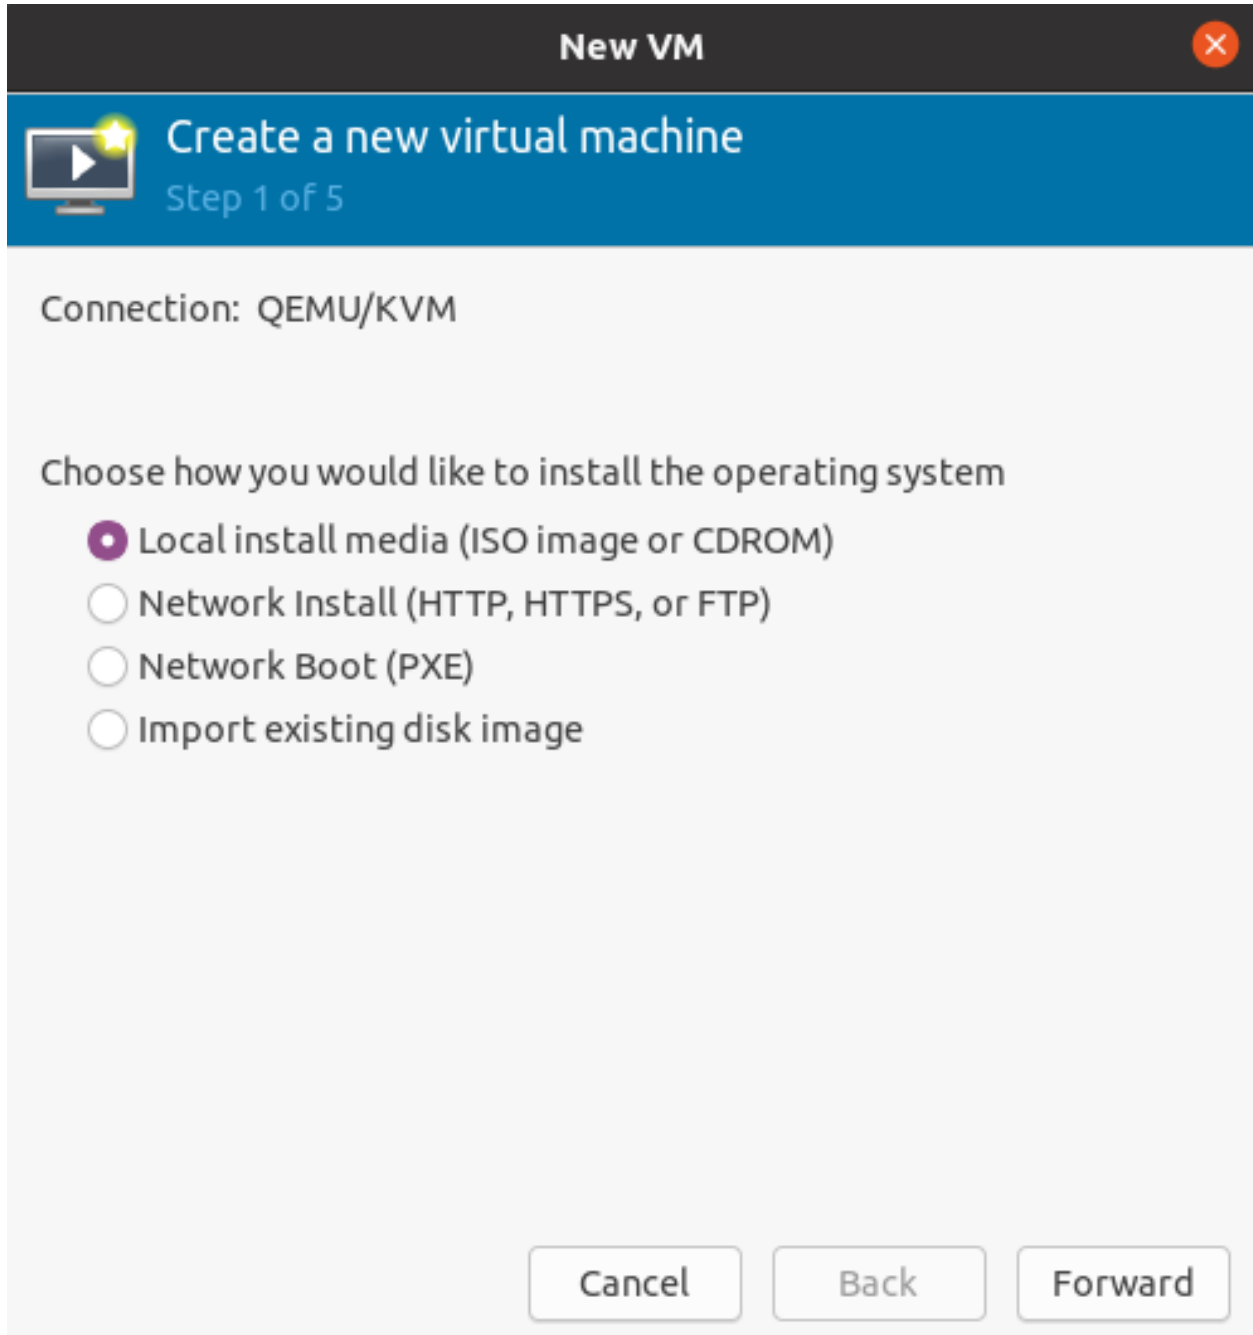

The system is fully operational.

Virt-manager

The virt-manager application is a desktop user interface for managing virtual machines through libvirt. On the linux open VMM (Virtual Machine Manager).

Deploy from ISO

1. Open VMM and Create a new VM (Virtual Machine)
2. Choose Local install media (ISO)
3. Choose path to iso vyos.iso. Operating System can be any Debian based.
4. Choose Memory and CPU
5. Disk size
6. Name of VM and network selection
7. Then you will be taken to the console.

4.2.3 Running on VMware ESXi

ESXi 5.5 or later

.ova files are available for supporting users, and a VyOS can also be stood up using a generic Linux instance, and attaching the bootable ISO file and installing from the ISO using the normal process around *install image*.

Note: There have been previous documented issues with GRE/IPSEC tunneling using the E1000 adapter on the VyOS guest, and use of the VMXNET3 has been advised.

Memory Contention Considerations

When the underlying ESXi host is approaching ~92% memory utilisation it will start the balloon process in a ‘soft’ state to start reclaiming memory from guest operating systems. This causes an artificial pressure using the vmmemctl driver on memory usage on the virtual guest. As VyOS by default does not have a swap file, this vmmemctl pressure is unable to force processes to move in memory data to the paging file, and blindly consumes memory forcing the virtual guest into a low memory state with no way to escape. The balloon can expand to 65% of guest allocated memory, so a VyOS guest running >35% of memory usage, can encounter an out of memory situation, and trigger the kernel oom_kill process. At this point a weighted lottery favouring memory hungry processes will be run with the unlucky winner being terminated by the kernel.

It is advised that VyOS routers are configured in a resource group with adequate memory reservations so that ballooning is not inflicted on virtual VyOS guests.

4.2.4 Running on GNS3

Sometimes you may want to test VyOS in a lab environment. **GNS3** is a network emulation software you might use for it.

This guide will provide the necessary steps for installing and setting up VyOS on GNS3.

Requirements

The following items are required:

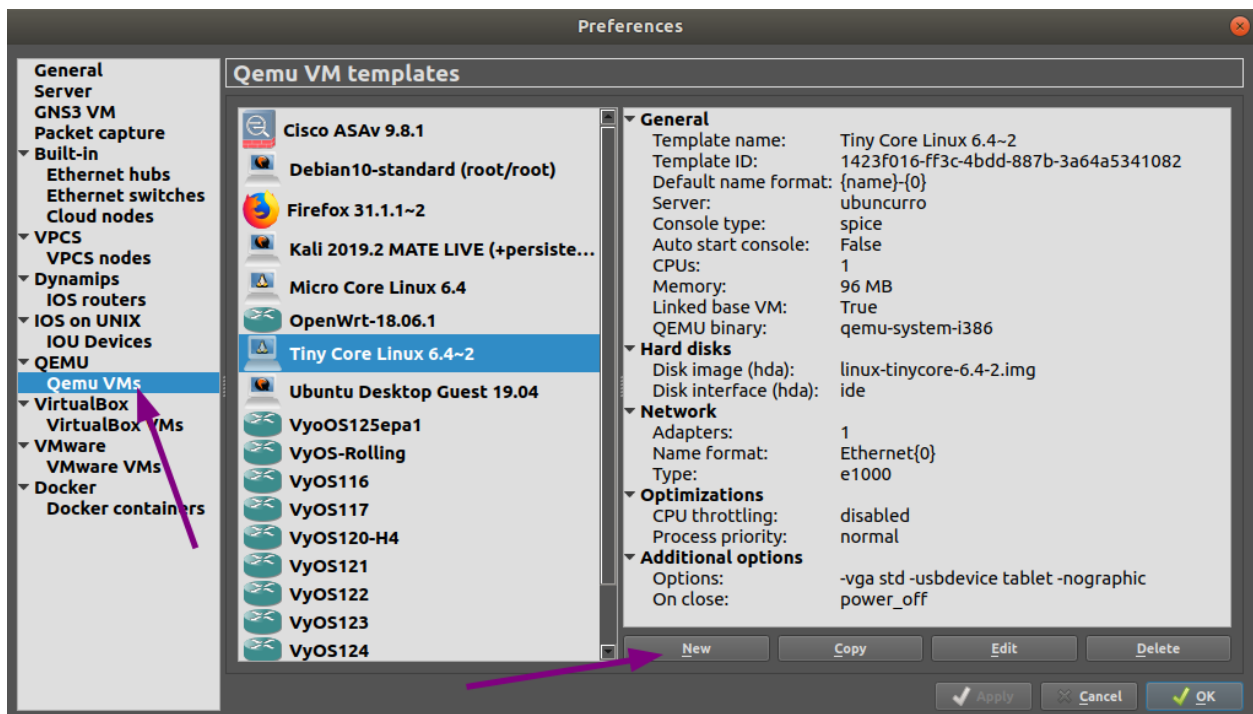

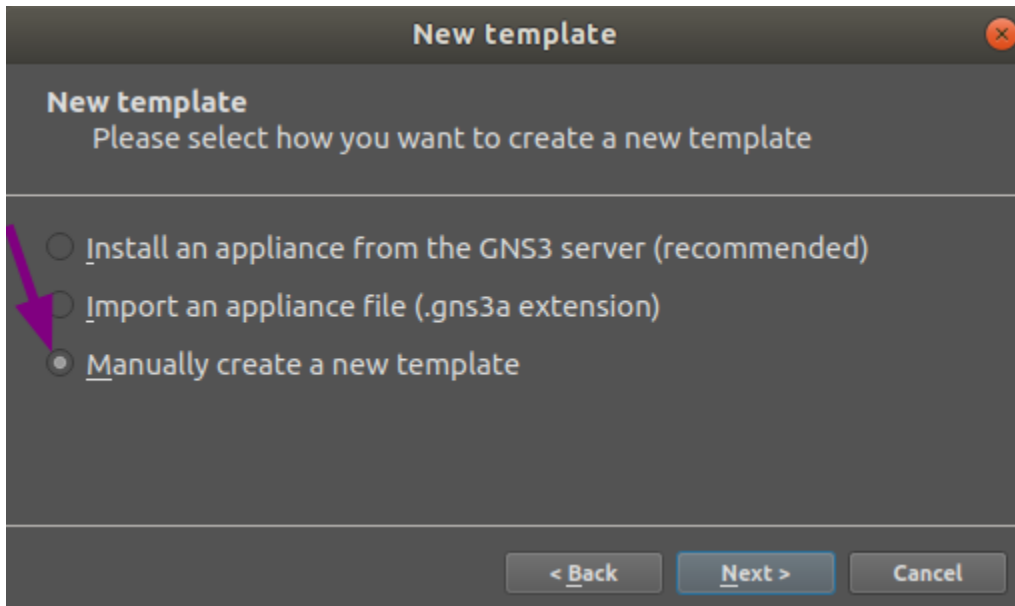

- A VyOS installation image (.iso file). You can find how to get it on the *Installation* page
- A working GNS3 installation. For further information see the **GNS3** documentation.

VM setup

First, a virtual machine (VM) for the VyOS installation must be created in GNS3.

Go to the GNS3 **File** menu, click **New template** and choose select **Manually create a new Template**.

Select **Quemu VMs** and then click on the **New** button.

QEMU VM name
Please choose a descriptive name for your new QEMU virtual machine.

Name:

☐ This is a legacy ASA VM

< Back Next > Cancel

Write a name for your VM, for instance “VyOS”, and click **Next**.

Select **qemu-system-x86_64** as Qemu binary, then **512MB** of RAM and click **Next**.

Select **telnet** as your console type and click **Next**.

Select **New image** for the base disk image of your VM and click **Create**.

Use the defaults in the **Binary and format** window and click **Next**.

Use the defaults in the **Qcow2 options** window and click **Next**.

Set the disk size to 2000 MiB, and click **Finish** to end the **Qemu image creator**.

Click **Finish** to end the **New QEMU VM template** wizard.

Now the VM settings have to be edited.

Being again at the **Preferences** window, having **Qemu VMs** selected and having our new VM selected, click the **Edit** button.

In the **General settings** tab of your **QEMU VM template configuration**, do the following:

- Click on the **Browse . . .** button to choose the **Symbol** you want to have representing your VM.
- In **Category** select in which group you want to find your VM.
- Set the **Boot priority** to **CD/DVD-ROM**.

At the **HDD** tab, change the Disk interface to **sata** to speed up the boot process.

At the **CD/DVD** tab click on `Browse . . .` and locate the VyOS image you want to install.

Note: You probably will want to accept to copy the `.iso` file to your default image directory when you are asked.

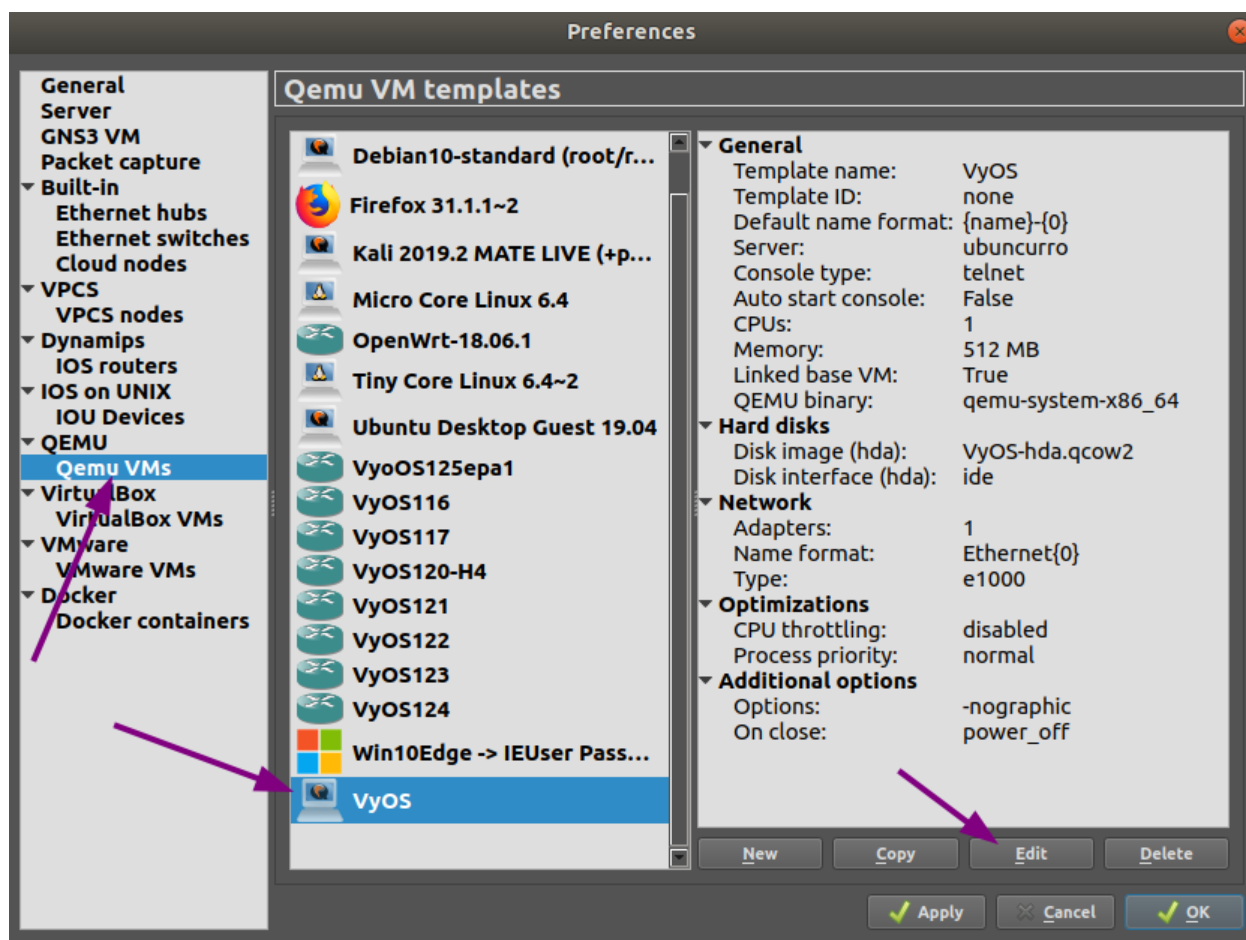

In the **Network** tab, set **0** as the number of adapters, set the **Name format** to `eth{0}` and the **Type** to **Paravirtualized Network I/O (virtio-net-pci)**.

In the **Advanced** tab, unmark the checkbox **Use as a linked base VM** and click **OK**, which will save and close the **QEMU VM template configuration** window.

At the general **Preferences** window, click **OK** to save and close.

VyOS installation

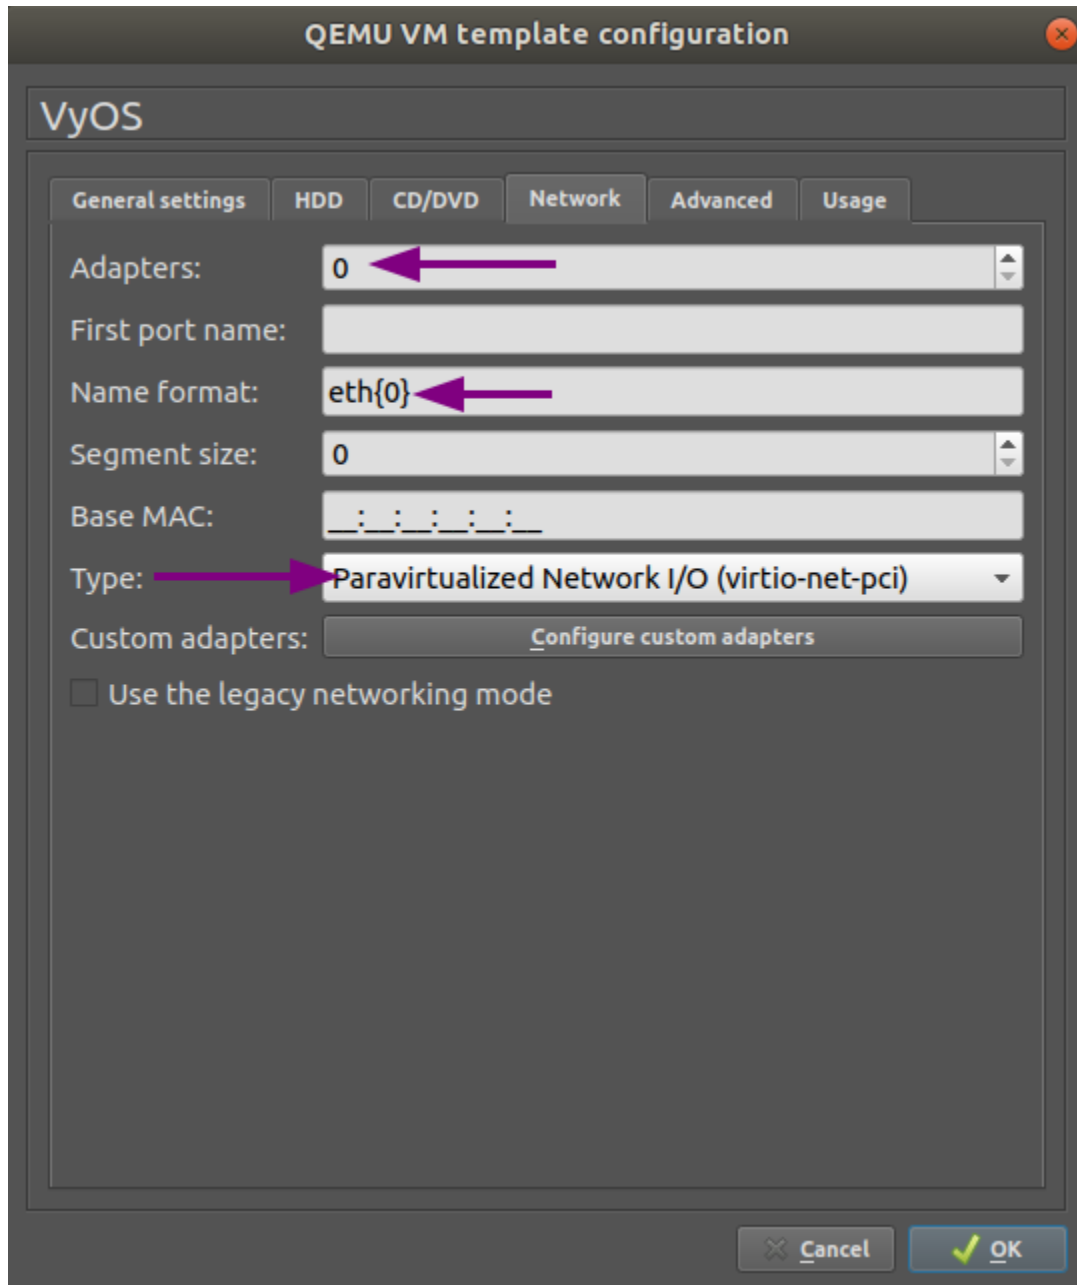

- Create a new project.
- Drag the newly created VyOS VM into it.
- Start the VM.
- Open a console. The console should show the system booting. It will ask for the login credentials, you are at the VyOS live system.
- **Install VyOS** as normal (that is, using the `install image` command).
- After a successful installation, shutdown the VM with the `poweroff` command.
- **Delete the VM** from the GNS3 project.

The `VyOS-hda.qcow2` file now contains a working VyOS image and can be used as a template. But it still needs some fixes before we can deploy VyOS in our labs.

VyOS VM configuration

To turn the template into a working VyOS machine, further steps are necessary as outlined below:

General settings tab: Set the boot priority to **HDD**

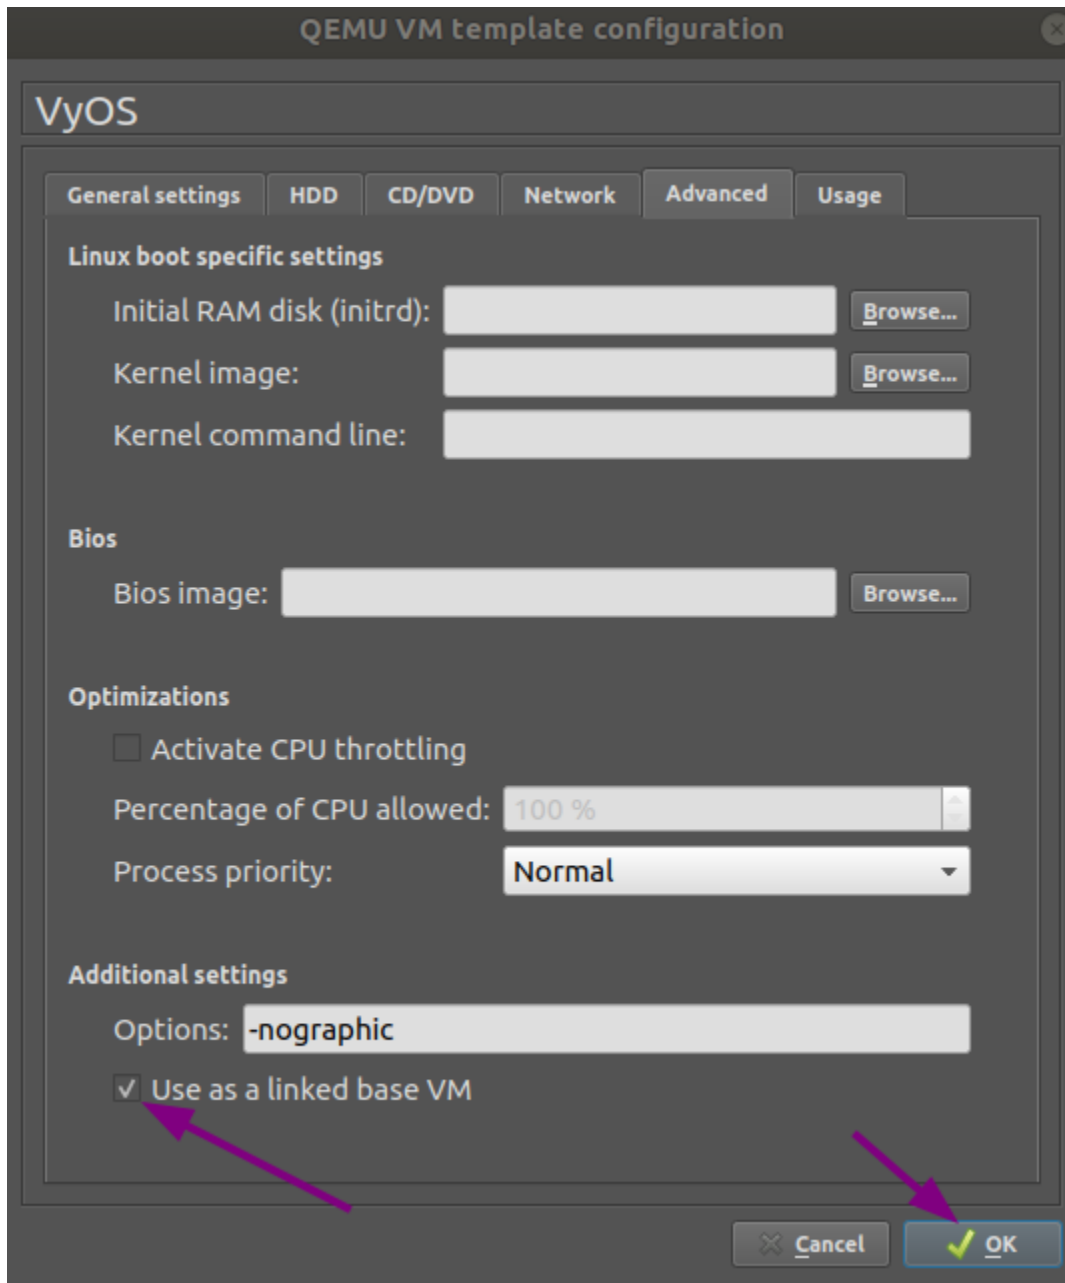

CD/DVD tab: Unmount the installation image file by clearing the **Image** entry field.

Set the number of required network adapters, for example **4**.

Advanced settings tab: Mark the checkbox **Use as a linked base VM** and click OK to save the changes.

The VyOS VM is now ready to be deployed.

4.2.5 EVE-NG

4.3 Running VyOS in Cloud Environments

4.3.1 Amazon AWS

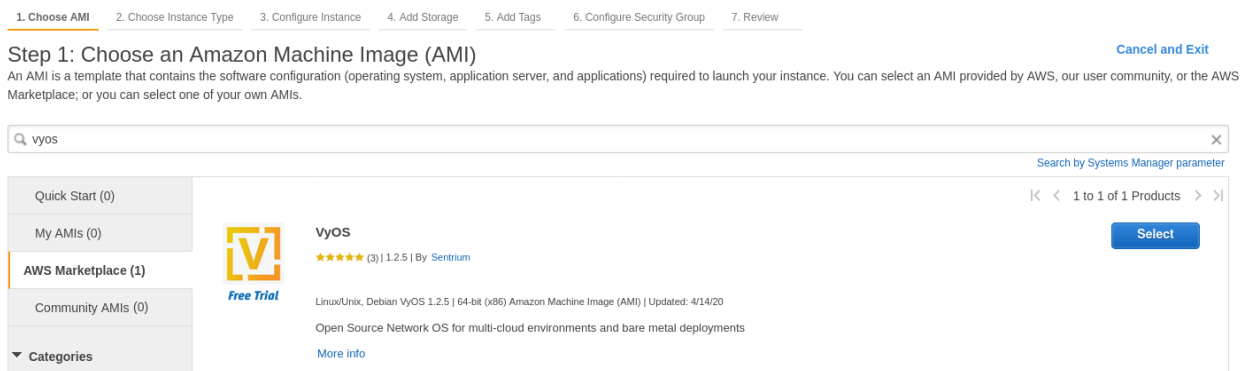

Deploy VM

Deploy VyOS on Amazon AWS (Amazon Web Services)

1. Click to Instances and Launch Instance

2. On the marketplace search “VyOS”

3. Choose the instance type. Minimum recommendation start from `m3.medium`
4. Configure instance for your requirements. Select number of instances / network / subnet
5. Additional storage. You can remove additional storage `/dev/sdb`. First root device will be `/dev/xvda`. You can keep this step.

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

Step 2: Choose an Instance Type

<input type="checkbox"/>	General purpose	m3.2xlarge	8	30	2 x 80 (SSD)	Yes	High	-
<input type="checkbox"/>	General purpose	m3.large	2	7.5	1 x 32 (SSD)	-	Moderate	-
<input checked="" type="checkbox"/>	General purpose	m3.medium	1	3.75	1 x 4 (SSD)	-	Moderate	-
<input type="checkbox"/>	General purpose	m3.xlarge	4	15	2 x 40 (SSD)	Yes	High	-

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

Step 3: Configure Instance Details

Configure the instance to suit your requirements. You can launch multiple instances from the same AMI, request Spot instances to take advantage of the lower pricing, assign an access management role to the instance, and more.

Number of instances	<input type="text" value="1"/>	Launch into Auto Scaling Group
Purchasing option	<input type="checkbox"/> Request Spot instances	
Network	<input type="text" value="vpc (default)"/>	Create new VPC
Subnet	<input type="text" value="No preference (default subnet in any Availability Zone)"/>	Create new subnet
Auto-assign Public IP	<input type="text" value="Use subnet setting (Enable)"/>	
Placement group	<input type="checkbox"/> Add instance to placement group	
Capacity Reservation	<input type="text" value="Open"/>	Create new Capacity Reservation
IAM role	<input type="text" value="None"/>	Create new IAM role
Shutdown behavior	<input type="text" value="Stop"/>	
Stop - Hibernate behavior	<input type="checkbox"/> Enable hibernation as an additional stop behavior	
Enable termination protection	<input type="checkbox"/> Protect against accidental termination	
Monitoring	<input type="checkbox"/> Enable CloudWatch detailed monitoring	

[Cancel](#) [Previous](#) [Review and Launch](#) [Next: Add Storage](#)

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

Step 4: Add Storage

Your instance will be launched with the following storage device settings. You can attach additional EBS volumes and instance store volumes to your instance, or edit the settings of the root volume. You can also attach additional EBS volumes after launching an instance, but not instance store volumes. [Learn more](#) about storage options in Amazon EC2.

Volume Type	Device	Snapshot	Size (GiB)	Volume Type	IOPS	Throughput (MB/s)	Delete on Termination	Encryption
Root	/dev/xvda	snap-0cdde1302124a73fc	<input type="text" value="4"/>	General Purpose SSD (gp2)	100 / 3000	N/A	<input checked="" type="checkbox"/>	Not Encrypted
Instance Store 0	/dev/sdb	N/A	4	SSD	N/A	N/A	N/A	Not Encrypted

[Add New Volume](#)

Free tier eligible customers can get up to 30 GB of EBS General Purpose (SSD) or Magnetic storage. [Learn more](#) about free usage tier eligibility and usage restrictions.

[Cancel](#) [Previous](#) [Review and Launch](#) [Next: Add Tags](#)

6. Configure Security Group. It's recommended that you configure ssh access only from certain address sources. Or permit any (by default).

1. Choose AMI 2. Choose Instance Type 3. Configure Instance 4. Add Storage 5. Add Tags 6. Configure Security Group 7. Review

Step 6: Configure Security Group

A security group is a set of firewall rules that control the traffic for your instance. On this page, you can add rules to allow specific traffic to reach your instance. For example, if you want to set up a web server and allow Internet traffic to reach your instance, add rules that allow unrestricted access to the HTTP and HTTPS ports. You can create a new security group or select from an existing one below. [Learn more](#) about Amazon EC2 security groups.

Assign a security group: ☒ Create a new security group
☐ Select an existing security group

Security group name:

Description:

Type ⓘ	Protocol ⓘ	Port Range ⓘ	Source ⓘ	Description ⓘ
SSH ▾	TCP	22	Custom ▾ 0.0.0.0/0	e.g. SSH for Admin Desktop

 **Warning**
 Rules with source of 0.0.0.0/0 allow all IP addresses to access your instance. We recommend setting security group rules to allow access from known IP addresses only.

7. Select SSH key pair and click Launch Instances
8. Find out your public IP address.
9. Connect to the instance by SSH key.

```
ssh -i ~/.ssh/amazon.pem vyos@203.0.113.3
vyos@ip-192-0-2-10:~$
```

4.3.2 Azure

Deploy VM

Deploy VyOS on Azure.

1. Go to the Azure services and Click to **Add new Virtual machine**
2. Choose vm name, resource group, region and click **Browse all public and private images**
3. On the marketplace search VyOS and choose the appropriate subscription
4. Generate new SSH key pair or use existing.
5. Define network, subnet, Public IP. Or it will be created by default.
6. Click Review + create. After a few seconds your deployment will be complete
7. Click to your new vm and find out your Public IP address.
8. Connect to the instance by SSH key.

Select an existing key pair or create a new key pair

A key pair consists of a **public key** that AWS stores, and a **private key file** that you store. Together, they allow you to connect to your instance securely. For Windows AMIs, the private key file is required to obtain the password used to log into your instance. For Linux AMIs, the private key file allows you to securely SSH into your instance.

Note: The selected key pair will be added to the set of keys authorized for this instance. Learn more about [removing existing key pairs from a public AMI](#).

Choose an existing key pair

Select a key pair

temp

☒ I acknowledge that I have access to the selected private key file (temp.pem), and that without this file, I won't be able to log into my instance.

Cancel

Launch Instances

Add interface

If instance was deployed with one **eth0** WAN interface and want to add new one. To add new interface an example **eth1** LAN you need shutdown the instance. Attach the interface in the Azure portal and then start the instance.

Note: Azure does not allow you attach interface when the instance in the **Running** state.

Absorbing Routes

If using as a router, you will want your LAN interface to absorb some or all of the traffic from your VNET by using a route table applied to the subnet.

1. Create a route table and browse to **Configuration**
2. Add one or more routes for networks you want to pass through the VyOS VM. Next hop type **Virtual Appliance** with the **Next Hop Address** of the VyOS LAN interface.

Note: If you want to create a new default route for VMs on the subnet, use **Address Prefix** `0.0.0.0/0` Also note that if you want to use this as a typical edge device, you'll want masquerade NAT for the WAN interface.

Serial Console

Azure has a way to access the serial console of a VM, but this needs to be configured on the VyOS. It's there by default, but keep it in mind if you are replacing config.boot and rebooting: `set system console device ttyS0 speed '9600'`

4.3.3 Google Cloud Platform

Deploy VM

To deploy VyOS on GCP (Google Cloud Platform)

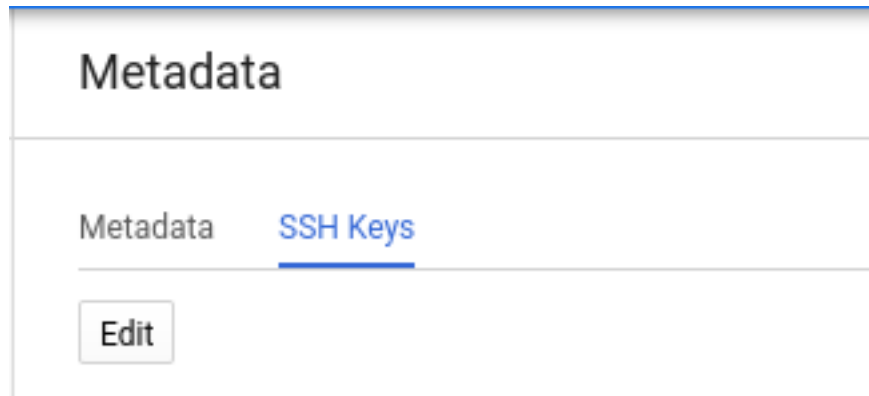

1. Generate SSH key pair type **ssh-rsa** from the host that will connect to VyOS.

Example:

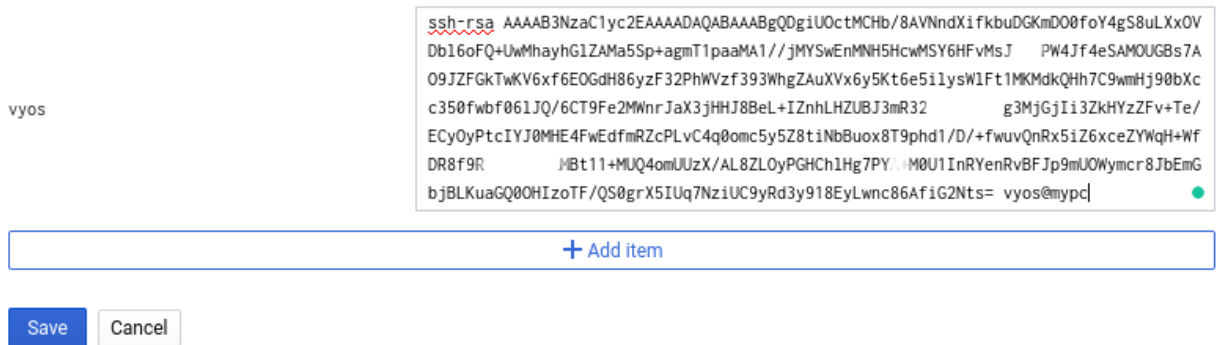

```
ssh-keygen -t rsa -f ~/.ssh/vyos_gcp -C "vyos@mypc"
```

Note: In name “**vyos@mypc**” The first value must be “**vyos**”. Because default user is vyos and google api uses this option.

2. Open GCP console and navigate to the menu **Metadata**. Choose **SSH Keys** and click **edit**.

Click **Add item** and paste your public ssh key. Click **Save**.

2. On marketplace search “VyOS”
3. Change Deployment name/Zone/Machine type and click **Deploy**
4. After few seconds click to **instance**
5. Find out your external IP address
6. Connect to the instance. SSH key was generated in the first step.

```
ssh -i ~/.ssh/vyos_gcp vyos@203.0.113.3
vyos@vyos-r1-vm:~$
```

4.3. Running VyOS in Cloud Environments

158

4.4 Running on Bare Metal

4.4.1 Supermicro A2SDi (Atom C3000)

I opted to get one of the new Intel Atom C3000 CPUs to spawn VyOS on it. Running VyOS on an UEFI only device is supported as of VyOS release 1.2.

Shopping Cart

- 1x Supermicro CSE-505-203B (19" 1U chassis, inkl. 200W PSU)
- 1x Supermicro MCP-260-00085-0B (I/O Shield for A2SDi-2C-HLN4F)
- 1x Supermicro A2SDi-2C-HLN4F (Intel Atom C3338, 2C/2T, 4MB cache, Quad LAN with Intel C3000 SoC 1GbE)
- 1x Crucial CT4G4DFS824A (4GB DDR4 RAM 2400 MT/s, PC4-19200)
- 1x SanDisk Ultra Fit 32GB (USB-A 3.0 SDCZ43-032G-G46 mass storage for OS)
- 1x Supermicro MCP-320-81302-0B (optional FAN tray)

Optional (10GE)

If you want to get additional ethernet ports or even 10GE connectivity the following optional parts will be required:

- 1x Supermicro RSC-RR1U-E8 (Riser Card)
- 1x Supermicro MCP-120-00063-0N (Riser Card Bracket)

Latest VyOS rolling releases boot without any problem on this board. You also receive a nice IPMI interface realized with an ASPEED AST2400 BMC (no information about [OpenBMC](#) so far on this motherboard).

Pictures

4.4.2 PC Engines APU4

As this platform seems to be quite common in terms of noise, cost, power and performance it makes sense to write a small installation manual.

This guide was developed using an APU4C4 board with the following specs:

- AMD Embedded G series GX-412TC, 1 GHz quad Jaguar core with 64 bit and AES-NI support, 32K data + 32K instruction cache per core, shared 2MB L2 cache.
- 4 GB DDR3-1333 DRAM, with optional ECC support
- About 6 to 10W of 12V DC power depending on CPU load
- 2 miniPCI express (one with SIM socket for 3G modem).
- 4 Gigabit Ethernet channels using Intel i211AT NICs

The board can be powered via 12V from the front or via a 5V onboard connector.

Shopping Cart

- 1x apu4c4 = 4 i211AT LAN / AMD GX-412TC CPU / 4 GB DRAM / dual SIM
- 1x Kingston SUV500MS/120G
- 1x VARIA Group Item 326745 19" dual rack for APU4

The 19" enclosure can accommodate up to two APU4 boards - there is a single and dual front cover.

Extension Modules

WiFi

Refer to [WLAN/WIFI - Wireless LAN](#) for additional information, below listed modules have been tested successfully on this Hardware platform:

- Compex WLE900VX mini-PCIe WiFi module, only supported in mPCIe slot 1.

WWAN

Refer to [WWAN - Wireless Wide-Area-Network](#) for additional information, below listed modules have been tested successfully on this Hardware platform using VyOS 1.3 (equuleus):

- Sierra Wireless AirPrime MC7304 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7430 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7455 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7710 miniPCIe card (LTE)
- Huawei ME909u-521 miniPCIe card (LTE)

Note: Once you `commit` the above changes access to the serial interface is lost until you set your terminal emulator to 115200 8N1 again.

```
vyos@vyos# show system console
device ttyS0 {
    speed 115200
}
```

VyOS 1.2 (rolling)

Installing the rolling release on an APU2 board does not require any change on the serial console from your host side as [T1327](#) was successfully implemented.

Simply proceed with a regular image installation as described in [Installation](#).

Pictures

Note: Both device types operate without any moving parts and emit zero noise.

Rack Mount

VyOS custom print

Desktop / Bench Top

4.4.3 Qotom Q355G4

The install on this Q355G4 box is pretty much plug and play. The port numbering the OS does might differ from the labels on the outside, but the UEFI firmware has a port blink test built in with MAC addresses so you can very quickly identify which is which. MAC labels are on the inside as well, and this test can be done from VyOS or plain Linux too. Default settings in the UEFI will make it boot, but depending on your installation wishes (i.e. storage type, boot type, console type) you might want to adjust them. This Qotom company seems to be the real OEM/ODM for many other relabelling companies like Protectli.

Hardware

There are a number of other options, but they all seem to be close to Intel reference designs, with added features like more serial ports, more network interfaces and the likes. Because they don't deviate too much from standard designs all the hardware is well-supported by mainline. It accepts one LPDDR3 SO-DIMM, but chances are that if you need more than that, you'll also want something even beefier than an i5. There are options for antenna holes, and SIM slots, so you could in theory add an LTE/Cell modem (not tested so far).

The chassis is a U-shaped alu extrusion with removable I/O plates and removable bottom plate. Cooling is completely passive with a heatsink on the SoC with internal and external fins, a flat interface surface, thermal pad on top of that, which then directly attaches to the chassis, which has fins as well. It comes with mounting hardware and rubber feet, so you could place it like a desktop model or mount it on a VESA mount, or even wall mount it with the provided mounting plate. The closing plate doubles as internal 2.5" mounting place for an HDD or SSD, and comes supplied with a small SATA cable and SATA power cable.

Power supply is a 12VDC barrel jack, and included switching power supply, which is why SATA power regulation is on-board. Internally it has a NUC-board-style on-board 12V input header as well, the molex locking style.

There are WDT options and auto-boot on power enable, which is great for remote setups. Firmware is reasonably secure (no backdoors found, BootGuard is enabled in enforcement mode, which is good but also means no coreboot option), yet has most options available to configure (so it's not locked out like most firmwares are).

An external RS232 serial port is available, internally a GPIO header as well. It does have Realtek based audio on board for some reason, but you can disable that. Booting works on both USB2 and USB3 ports. Switching between serial BIOS mode and HDMI BIOS mode depends on what is connected at startup; it goes into serial mode if you disconnect HDMI and plug in serial, in all other cases it's HDMI mode.

4.4.4 Partaker i5

I believe this is actually the same hardware as the Protectli. I purchased it in June 2018. It came pre-loaded with pfSense.

[Manufacturer product page.](#)

Installation

- Write VyOS ISO to USB drive of some sort
- Plug in VGA, power, USB keyboard, and USB drive
- Press “SW” button on the front (this is the power button; I don’t know what “SW” is supposed to mean).
- Begin rapidly pressing delete on the keyboard. The boot prompt is very quick, but with a few tries you should be able to get into the BIOS.
- Chipset > South Bridge > USB Configuration: set XHCI to Disabled and USB 2.0 (EHCI) to Enabled. Without doing this, the USB drive won’t boot.
- Boot to the VyOS installer and install as usual.

Warning the interface labels on my device are backwards; the left-most “LAN4” port is eth0 and the right-most “LAN1” port is eth3.

4.4.5 Acrosser AND-J190N1

This microbox network appliance was build to create OpenVPN bridges. It can saturate a 100Mbps link. It is a small (serial console only) PC with 6 Gb LAN http://www.acrosser.com/upload/AND-J190_J180N1-2.pdf

You may have to add your own RAM and HDD/SSD. There is no VGA connector. But Acrosser provides a DB25 adapter for the VGA header on the motherboard (not used).

BIOS Settings:

First thing you want to do is getting a more user friendly console to configure BIOS. Default VT100 brings a lot of issues. Configure VT100+ instead.

For practical issues change speed from 115200 to 9600. 9600 is the default speed at which both linux kernel and VyOS will reconfigure the serial port when loading.

Connect to serial (115200bps). Power on the appliance and press Del in the console when requested to enter BIOS settings.

Advanced > Serial Port Console Redirection > Console Redirection Settings:

- Terminal Type : VT100+
- Bits per second : 9600

Save, reboot and change serial speed to 9600 on your client.

Some options have to be changed for VyOS to boot correctly. With XHCI enabled the installer can't access the USB key. Enable EHCI instead.

Reboot into BIOS, Chipset > South Bridge > USB Configuration:

- Disable XHCI
- Enable USB 2.0 (EHCI) Support

Install VyOS:

Create a VyOS bootable USB key. I used the 64-bit ISO (VyOS 1.1.7) and [LinuxLive USB Creator](#).

I'm not sure if it helps the process but I changed default option to live-serial (line "default xxxx") on the USB key under `syslinux/syslinux.cfg`.

I connected the key to one black USB port on the back and powered on. The first VyOS screen has some readability issues. Press `Enter` to continue.

Then VyOS should boot and you can perform the `install image`

4.5 Update VyOS

New system images can be added using the `add system image` command. The command will extract the chosen image and will prompt you to use the current system configuration and SSH security keys, allowing for the new image to boot using the current configuration.

Note: Only LTS releases are PGP-signed.

add system image <url | path> [vrf name] [username user [password pass]]

Use this command to install a new system image. You can reach the image from the web (<http://>, <https://>) or from your local system, e.g. `/tmp/vyos-1.2.3-amd64.iso`.

The `add system image` command also supports installing new versions of VyOS through an optional given VRF. Also if URL in question requires authentication, you can specify an optional username and password via the commandline which will be passed as "Basic-Auth" to the server.

If there is not enough **free disk space available**, the installation will be canceled. To delete images use the `delete system image` command.

VyOS configuration is associated to each image, and **each image has a unique copy of its configuration**. This is different than a traditional network router where the configuration is shared across all images.

Note: If you have any personal files, like some scripts you created, and you don't want them to be lost during the upgrade, make sure those files are stored in `/config` as this directory is always copied to newer installed images.

You can access files from a previous installation and copy them to your current image if they were located in the `/config` directory. This can be done using the `copy` command. So, for instance, in order to copy `/config/config.boot` from VyOS 1.2.1 image, you would use the following command:

```
copy file 1.2.1://config/config.boot to /tmp/config.boot.1.2.1
```

4.5.1 Example

```
vyos@vyos:~$ add system image https://downloads.vyos.io/rolling/current/amd64/vyos-
→rolling-latest.iso
Trying to fetch ISO file from https://downloads.vyos.io/rolling/current/amd64/vyos-

curl: (22) The requested URL returned error: 404 Not Found

Unable to fetch digital signature file.
Do you want to continue without signature check? (yes/no) [yes]
Checking MD5 checksums of files on the ISO image...OK.
Done!

What would you like to name this image? [vyos-1.3-rolling-201912201452]:

OK.  This image will be named: vyos-1.3-rolling-201912201452

```

Hint: The most up-to-date Rolling Release for AMD64 can be accessed using the following URL:

<https://downloads.vyos.io/rolling/current/amd64/vyos-rolling-latest.iso>

After reboot you might want to verify the version you are running with the `show version` command.

4.6 Image Management

The VyOS image-based installation is implemented by creating a directory for each image on the storage device selected during the install process.

The directory structure of the boot device:

```

/
/boot
/boot/grub
/boot/1.2.0-rolling+201810021347

```

The image directory contains the system kernel, a compressed image of the root filesystem for the OS, and a directory for persistent storage, such as configuration. On boot, the system will extract the OS image into memory and mount the appropriate live-rw sub-directories to provide persistent storage system configuration.

This process allows for a system to always boot to a known working state, as the OS image is fixed and non-persistent. It also allows for multiple releases of VyOS to be installed on the same storage device. The image can be selected manually at boot if needed, but the system will otherwise boot the image configured to be the default.

show system image

List all available system images which can be booted on the current system.

```

vyos@vyos:~$ show system image
The system currently has the following image(s) installed:

  1: 1.2.0-rolling+201810021347 (default boot)
  2: 1.2.0-rolling+201810021217
  3: 1.2.0-rolling+201809252218

```

delete system image [image-name]

Delete no longer needed images from the system. You can specify an optional image name to delete, the image name can be retrieved via a list of available images can be shown using the `show system image`.

```
vyos@vyos:~$ delete system image
The following image(s) can be deleted:

  1: 1.3-rolling-201912181733 (default boot) (running image)
  2: 1.3-rolling-201912180242
  3: 1.2.2
  4: 1.2.1

Select the image to delete: 2

Are you sure you want to delete the
"1.3-rolling-201912180242" image? (Yes/No) [No]: y
Deleting the "1.3-rolling-201912180242" image...
Done
```

show version

Show current system image version.

```
vyos@vyos:~$ show version
Version:          VyOS 1.3-rolling-201912181733
Built by:         autobuild@vyos.net

```

4.6.1 System rollback

If you need to rollback to a previous image, you can easily do so. First check the available images through the `show system image` command and then select your image with the following command:

set system image default-boot [image-name]

Select the default boot image which will be started on the next boot of the system.

Then reboot the system.

Note: VyOS automatically associates the configuration to the image, so you don't need to worry about that. Each image has a unique copy of its configuration.

If you have access to the console, there is a another way to select your booting image: reboot and use the GRUB menu at startup.

4.7 Migrate from Vyatta Core

VyOS 1.x line aims to preserve backward compatibility and provide a safe upgrade path for existing Vyatta Core users. You may think of VyOS 1.0.0 as VC7.0.

4.7.1 Vyatta release compatibility

Vyatta Core releases from 6.5 to 6.6 should be 100% compatible.

Vyatta Core 6.4 and earlier may have incompatibilities. In Vyatta 6.5 the “modify” firewall was removed and replaced with the `set policy route` command family, old configs can not be automatically converted. You will have to adapt it to post-6.5 Vyatta syntax manually.

Note: Also, in Vyatta Core 6.5 remote access VPN interfaces have been renamed from `pppX` to `l2tpX` and `pptpX`. If you are using zone based firewalling in Vyatta Core pre-6.5 versions, make sure to change interface names in rules for remote access VPN.

4.7.2 Upgrade procedure

You just use `add system image`, as if it was a new VC release (see [Update VyOS](#) for additional information). The only thing you want to do is to verify the new images digital signature. You will have to add the public key manually once as it is not shipped the first time.

```
vyatta@vyatta:~$ wget http://wiki.vyos.net/so3group_maintainers.key
Connecting to vyos.net (x.x.x.x:80)
so3group_maintainers 100% |*****| 3125 --:--:-- ETA
vyatta@vyatta:~$ sudo apt-key add so3group_maintainers.key
OK
vyatta@vyatta:~$
```

For completion the key below corresponds to the key listed in the URL above.

```

vyatta@vyatta:~$ show system image
The system currently has the following image(s) installed:

  1: 1.0.0 (default boot)
  2: VC6.6R1 (running image)
```

Upon reboot, you should have a working installation of VyOS.

You can go back to your Vyatta install using the `set system image default-boot` command and selecting the your previous Vyatta Core image.

Note: Future releases of VyOS will break the direct upgrade path from Vyatta core. Please upgrade through an intermediate VyOS version e.g. VyOS 1.2. After this you can continue upgrading to newer releases once you bootet into VyOS 1.2 once.

This chapter will guide you on how to get up to speed quickly using your new VyOS system. It will show you a very basic configuration example that will provide a [NAT](#) gateway for a device with two network interfaces (*eth0* and *eth1*).

5.1 Configuration Mode

By default, VyOS is in operational mode, and the command prompt displays a \$. To configure VyOS, you will need to enter configuration mode, resulting in the command prompt displaying a #, as demonstrated below:

```
vyos@vyos$ configure
vyos@vyos#
```

5.2 Commit and Save

After every configuration change, you need to apply the changes by using the following command:

```
commit
```

Once your configuration works as expected, you can save it permanently by using the following command:

```
save
```

5.3 Interface Configuration

- Your outside/WAN interface will be *eth0*. It will receive its interface address via DHCP.
- Your internal/LAN interface will be *eth1*. It will use a static IP address of *192.168.0.1/24*.

After switching to [Configuration Mode](#) issue the following commands:

```
set interfaces ethernet eth0 address dhcp
set interfaces ethernet eth0 description 'OUTSIDE'
set interfaces ethernet eth1 address '192.168.0.1/24'
set interfaces ethernet eth1 description 'INSIDE'
```

5.4 SSH Management

After switching to *Configuration Mode* issue the following commands, and your system will listen on every interface for incoming SSH connections. You might want to check the *SSH* chapter on how to listen on specific addresses only.

```
set service ssh port '22'
```

5.5 DHCP/DNS quick-start

The following settings will configure DHCP and DNS services on your internal/LAN network, where VyOS will act as the default gateway and DNS server.

- The default gateway and DNS recursor address will be *192.168.0.1/24*
- The address range *192.168.0.2/24 - 192.168.0.8/24* will be reserved for static assignments
- DHCP clients will be assigned IP addresses within the range of *192.168.0.9 - 192.168.0.254* and have a domain name of *internal-network*
- DHCP leases will hold for one day (86400 seconds)
- VyOS will serve as a full DNS recursor, replacing the need to utilize Google, Cloudflare, or other public DNS servers (which is good for privacy)
- Only hosts from your internal/LAN network can use the DNS recursor

```
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 default-router
↪ '192.168.0.1'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 dns-server '192.
↪ 168.0.1'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 domain-name
↪ 'vyos.net'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 lease '86400'
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 range 0 start_
↪ 192.168.0.9
set service dhcp-server shared-network-name LAN subnet 192.168.0.0/24 range 0 stop
↪ '192.168.0.254'

set service dns forwarding cache-size '0'
set service dns forwarding listen-address '192.168.0.1'
set service dns forwarding allow-from '192.168.0.0/24'
```

5.6 NAT

The following settings will configure *SNAT* rules for our internal/LAN network, allowing hosts to communicate through the outside/WAN network via IP masquerade.

```
set nat source rule 100 outbound-interface 'eth0'
set nat source rule 100 source address '192.168.0.0/24'
set nat source rule 100 translation address masquerade
```

5.7 Firewall

Add a set of firewall policies for our outside/WAN interface.

This configuration creates a proper stateful firewall that blocks all traffic which was not initiated from the internal/LAN side first.

```
set firewall name OUTSIDE-IN default-action 'drop'
set firewall name OUTSIDE-IN rule 10 action 'accept'
set firewall name OUTSIDE-IN rule 10 state established 'enable'
set firewall name OUTSIDE-IN rule 10 state related 'enable'

set firewall name OUTSIDE-LOCAL default-action 'drop'
set firewall name OUTSIDE-LOCAL rule 10 action 'accept'
set firewall name OUTSIDE-LOCAL rule 10 state established 'enable'
set firewall name OUTSIDE-LOCAL rule 10 state related 'enable'
set firewall name OUTSIDE-LOCAL rule 20 action 'accept'
set firewall name OUTSIDE-LOCAL rule 20 icmp type-name 'echo-request'
set firewall name OUTSIDE-LOCAL rule 20 protocol 'icmp'
set firewall name OUTSIDE-LOCAL rule 20 state new 'enable'
```

If you wanted to enable SSH access to your firewall from the outside/WAN interface, you could create some additional rules to allow that kind of traffic.

These rules allow SSH traffic and rate limit it to 4 requests per minute. This blocks brute-forcing attempts:

```
set firewall name OUTSIDE-LOCAL rule 30 action 'drop'
set firewall name OUTSIDE-LOCAL rule 30 destination port '22'
set firewall name OUTSIDE-LOCAL rule 30 protocol 'tcp'
set firewall name OUTSIDE-LOCAL rule 30 recent count '4'
set firewall name OUTSIDE-LOCAL rule 30 recent time '60'
set firewall name OUTSIDE-LOCAL rule 30 state new 'enable'

set firewall name OUTSIDE-LOCAL rule 31 action 'accept'
set firewall name OUTSIDE-LOCAL rule 31 destination port '22'
set firewall name OUTSIDE-LOCAL rule 31 protocol 'tcp'
set firewall name OUTSIDE-LOCAL rule 31 state new 'enable'
```

Apply the firewall policies:

```
set interfaces ethernet eth0 firewall in name 'OUTSIDE-IN'
set interfaces ethernet eth0 firewall local name 'OUTSIDE-LOCAL'
```

Commit changes, save the configuration, and exit configuration mode:

```
vyos@vyos# commit
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
vyos@vyos# exit
vyos@vyos$
```

5.8 Hardening

Especially if you are allowing SSH remote access from the outside/WAN interface, there are a few additional configuration steps that should be taken.

Replace the default `vyos` system user:

```
set system login user myvyosuser authentication plaintext-password mysecurepassword
```

Set up *Key Based Authentication*:

```
set system login user myvyosuser authentication public-keys myusername@mydesktop type_↵  
↵ssh-rsa  
set system login user myvyosuser authentication public-keys myusername@mydesktop key_↵  
↵contents_of_id_rsa.pub
```

Finally, try and SSH into the VyOS install as your new user. Once you have confirmed that your new user can access your router without a password, delete the original `vyos` user and completely disable password authentication for *SSH*:

```
delete system login user vyos  
set service ssh disable-password-authentication
```

As above, commit your changes, save the configuration, and exit configuration mode:

```
vyos@vyos# commit  
vyos@vyos# save  
Saving configuration to '/config/config.boot'...  
Done  
vyos@vyos# exit  
vyos@vyos$
```

You now should have a simple yet secure and functioning router to experiment with further. Enjoy!

Command Line Interface

The VyOS CLI (Command-Line Interface) comprises an operational and a configuration mode.

6.1 Operational Mode

Operational mode allows for commands to perform operational system tasks and view system and service status, while configuration mode allows for the modification of system configuration.

The CLI provides a built-in help system. In the CLI the `?` key may be used to display available commands. The `TAB` key can be used to auto-complete commands and will present the help system upon a conflict or unknown value.

For example typing `sh` followed by the `TAB` key will complete to `show`. Pressing `TAB` a second time will display the possible sub-commands of the `show` command.

```
vyos@vyos:~$ s[tab]
set      show
```

Example showing possible show commands:

```
vyos@vyos:~$ show [tab]
Possible completions:
  arp          Show Address Resolution Protocol (ARP) information
  bridge       Show bridging information
  cluster      Show clustering information
  configuration Show running configuration
  conntrack    Show conntrack entries in the conntrack table
  conntrack-sync
               Show connection syncing information
  date         Show system date and time
  dhcp         Show Dynamic Host Configuration Protocol (DHCP) information
  dhcpv6       Show status related to DHCPv6
  disk         Show status of disk device
  dns          Show Domain Name Server (DNS) information
```

(continues on next page)

(continued from previous page)

```

file          Show files for a particular image
firewall      Show firewall information
flow-accounting
              Show flow accounting statistics
hardware      Show system hardware details
history       show command history
host          Show host information
incoming      Show ethernet input-policy information
: q

```

You can scroll up with the keys [Shift]+[PageUp] and scroll down with [Shift]+[PageDown].

When the output of a command results in more lines than can be displayed on the terminal screen the output is paginated as indicated by a : prompt.

When viewing in page mode the following commands are available:

- q key can be used to cancel output
- space will scroll down one page
- b will scroll back one page
- return will scroll down one line
- up-arrow and down-arrow will scroll up or down one line at a time respectively
- left-arrow and right-arrow can be used to scroll left or right in the event that the output has lines which exceed the terminal size.

6.2 Configuration Mode

To enter configuration mode use the `configure` command:

```

vyos@vyos:~$ configure
[edit]
vyos@vyos:~#

```

Note: Prompt changes from \$ to #. To exit configuration mode, type `exit`.

```

vyos@vyos:~# exit
exit
vyos@vyos:~$

```

See the configuration section of this document for more information on configuration mode.

Configuration Overview

VyOS makes use of a unified configuration file for the entire system's configuration: `/config/config.boot`. This allows easy template creation, backup, and replication of system configuration. A system can thus also be easily cloned by simply copying the required configuration files.

7.1 Terminology

A live VyOS system has three major types of configurations:

- **Active or running configuration** is the system configuration that is loaded and currently active (used by VyOS). Any change in the configuration will have to be committed to belong to the active/running configuration.
- **Working configuration** is the one that is currently being modified in configuration mode. Changes made to the working configuration do not go into effect until the changes are committed with the `commit` command. At which time the working configuration will become the active or running configuration.
- **Saved configuration** is the one saved to a file using the `save` command. It allows you to keep safe a configuration for future uses. There can be multiple configuration files. The default or “boot” configuration is saved and loaded from the file `/config/config.boot`.

7.1.1 Seeing and navigating the configuration

show configuration

View the current active configuration, also known as the running configuration, from the operational mode.

```
vyos@vyos:~$ show configuration
interfaces {
    ethernet eth0 {
        address dhcp
        hw-id 00:53:00:00:aa:01
    }
    loopback lo {
```

(continues on next page)

(continued from previous page)

```

    }
}
service {
    ssh {
        port 22
    }
}
system {
    config-management {
        commit-revisions 20
    }
    console {
        device ttyS0 {
            speed 9600
        }
    }
    login {
        user vyos {
            authentication {
                encrypted-password *****
            }
            level admin
        }
    }
    ntp {
        server 0.pool.ntp.org {
        }
        server 1.pool.ntp.org {
        }
        server 2.pool.ntp.org {
        }
    }
    syslog {
        global {
            facility all {
                level notice
            }
            facility protocols {
                level debug
            }
        }
    }
}
}

```

By default, the configuration is displayed in a hierarchy like the above example, this is only one of the possible ways to display the configuration. When the configuration is generated and the device is configured, changes are added through a collection of `set` and `delete` commands.

show configuration commands

Get a collection of all the set commands required which led to the running configuration.

```

vyos@vyos:~$ show configuration commands
set interfaces ethernet eth0 address 'dhcp'
set interfaces ethernet eth0 hw-id '00:53:dd:44:3b:0f'
set interfaces loopback 'lo'
set service ssh port '22'

```

(continues on next page)

(continued from previous page)

```

set system config-management commit-revisions '20'
set system console device ttyS0 speed '9600'
set system login user vyos authentication encrypted-password '$6$Vt68...QzF0'
set system login user vyos level 'admin'
set system ntp server '0.pool.ntp.org'
set system ntp server '1.pool.ntp.org'
set system ntp server '2.pool.ntp.org'
set system syslog global facility all level 'notice'
set system syslog global facility protocols level 'debug'

```

Both these `show` commands should be executed when in operational mode, they do not work directly in configuration mode. There is a special way on how to [Access *opmode* from *config mode*](#).

Hint: Use the `show configuration commands | strip-private` command when you want to hide private data. You may want to do so if you want to share your configuration on the [forum](#).

The config mode

When entering the configuration mode you are navigating inside a tree structure, to enter configuration mode enter the command `configure` when in operational mode.

```

vyos@vyos$ configure
[edit]
vyos@vyos#

```

Note: When going into configuration mode, prompt changes from `$` to `#`.

All commands executed here are relative to the configuration level you have entered. You can do everything from the top level, but commands will be quite lengthy when manually typing them.

The current hierarchy level can be changed by the `edit` command.

```

[edit]
vyos@vyos# edit interfaces ethernet eth0

[edit interfaces ethernet eth0]
vyos@vyos#

```

You are now in a sublevel relative to `interfaces ethernet eth0`, all commands executed from this point on are relative to this sublevel. Use either the `top` or `exit` command to go back to the top of the hierarchy. You can also use the `up` command to move only one level up at a time.

show

The `show` command within configuration mode will show the working configuration indicating line changes with `+` for additions, `>` for replacements and `-` for deletions.

Example:

```

vyos@vyos:~$ configure
[edit]
vyos@vyos# show interfaces

```

(continues on next page)

(continued from previous page)

```

    ethernet eth0 {
        description MY_OLD_DESCRIPTION
        disable
        hw-id 00:53:dd:44:3b:03
    }
    loopback lo {
    }
[edit]
vyos@vyos# set interfaces ethernet eth0 address dhcp
[edit]
vyos@vyos# set interfaces ethernet eth0 description MY_NEW_DESCRIPTION
[edit]
vyos@vyos# delete interfaces ethernet eth0 disable
[edit]
vyos@vyos# show interfaces
    ethernet eth0 {
+   address dhcp
>   description MY_NEW_DESCRIPTION
-   disable
    hw-id 00:53:dd:44:3b:03
    }
    loopback lo {
    }

```

It is also possible to display all *set* commands within configuration mode using `show | commands`

```

vyos@vyos# show interfaces ethernet eth0 | commands
set address dhcp
set hw-id 00:53:ad:44:3b:03

```

These commands are also relative to the level you are inside and only relevant configuration blocks will be displayed when entering a sub-level.

```

[edit interfaces ethernet eth0]
vyos@vyos# show
    address dhcp
    hw-id 00:53:ad:44:3b:03

```

Exiting from the configuration mode is done via the `exit` command from the top level, executing `exit` from within a sub-level takes you back to the top level.

```

[edit interfaces ethernet eth0]
vyos@vyos# exit
[edit]
vyos@vyos# exit
Warning: configuration changes have not been saved.

```

7.1.2 Editing the configuration

The configuration can be edited by the use of `set` and `delete` commands from within configuration mode.

set

Use this command to set the value of a parameter or to create a new element.

Configuration commands are flattened from the tree into ‘one-liner’ commands shown in `show configuration` commands from operation mode. Commands are relative to the level where they are executed and all redundant information from the current level is removed from the command entered.

```
[edit]
vyos@vyos# set interface ethernet eth0 address 192.0.2.100/24
```

```
[edit interfaces ethernet eth0]
vyos@vyos# set address 203.0.113.6/24
```

These two commands above are essentially the same, just executed from different levels in the hierarchy.

delete

To delete a configuration entry use the `delete` command, this also deletes all sub-levels under the current level you’ve specified in the `delete` command. Deleting an entry will also result in the element reverting back to its default value if one exists.

```
[edit interfaces ethernet eth0]
vyos@vyos# delete address 192.0.2.100/24
```

commit

Any change you do on the configuration, will not take effect until committed using the `commit` command in configuration mode.

```
vyos@vyos# commit
[edit]
vyos@vyos# exit
Warning: configuration changes have not been saved.
vyos@vyos:~$
```

save

Use this command to preserve configuration changes upon reboot. By default it is stored at `/config/config.boot`. In the case you want to store the configuration file somewhere else, you can add a local path, a SCP address, a FTP address or a TFTP address.

```
vyos@vyos# save
Saving configuration to '/config/config.boot'...
Done
```

```
vyos@vyos# save [tab]
Possible completions:
<Enter>          Save to system config file
<file>           Save to file on local machine
scp://<user>:<passwd>@<host>:</file> Save to file on remote machine
ftp://<user>:<passwd>@<host>:</file> Save to file on remote machine
tftp://<host>:</file>          Save to file on remote machine
vyos@vyos# save tftp://192.168.0.100/vyos-test.config.boot
Saving configuration to 'tftp://192.168.0.100/vyos-test.config.boot'...
##### 100.0%
Done
```

exit [discard]

Configuration mode can not be exited while uncommitted changes exist. To exit configuration mode without applying changes, the `exit discard` command must be used.

All changes in the working config will thus be lost.

```
vyos@vyos# exit
Cannot exit: configuration modified.
Use 'exit discard' to discard the changes and exit.
[edit]
vyos@vyos# exit discard
```

commit-confirm <minutes>

Use this command to temporarily commit your changes and set the number of minutes available for validation. `confirm` must be entered within those minutes, otherwise the system will reboot into the previous configuration. The default value is 10 minutes.

What if you are doing something dangerous? Suppose you want to setup a firewall, and you are not sure there are no mistakes that will lock you out of your system. You can use confirmed commit. If you issue the `commit-confirm` command, your changes will be committed, and if you don't issue the `confirm` command in 10 minutes, your system will reboot into previous config revision.

```
vyos@router# set interfaces ethernet eth0 firewall local name FromWorld
vyos@router# commit-confirm
commit confirm will be automatically reboot in 10 minutes unless confirmed
Proceed? [confirm]y
[edit]
vyos@router# confirm
[edit]
```

Note: A reboot because you did not enter `confirm` will not take you necessarily to the *saved configuration*, but to the point before the unfortunate commit.

copy

Copy a configuration element.

You can copy and remove configuration subtrees. Suppose you set up a firewall ruleset `FromWorld` with one rule that allows traffic from specific subnet. Now you want to setup a similar rule, but for different subnet. Change your edit level to `firewall name FromWorld` and use `copy rule 10 to rule 20`, then modify rule 20.

```
vyos@router# show firewall name FromWorld
default-action drop
rule 10 {
    action accept
    source {
        address 203.0.113.0/24
    }
}
[edit]
vyos@router# edit firewall name FromWorld
[edit firewall name FromWorld]
vyos@router# copy rule 10 to rule 20
[edit firewall name FromWorld]
vyos@router# set rule 20 source address 198.51.100.0/24
[edit firewall name FromWorld]
vyos@router# commit
[edit firewall name FromWorld]
```

rename

Rename a configuration element.

You can also rename config subtrees:

```
vyos@router# rename rule 10 to rule 5
[edit firewall name FromWorld]
vyos@router# commit
[edit firewall name FromWorld]
```

Note that `show` command respects your edit level and from this level you can view the modified firewall ruleset with just `show` with no parameters.

```
vyos@router# show
default-action drop
rule 5 {
    action accept
    source {
        address 203.0.113.0/24
    }
}
rule 20 {
    action accept
    source {
        address 198.51.100.0/24
    }
}
```

comment <config node> "comment text"

Add comment as an annotation to a configuration node.

The `comment` command allows you to insert a comment above the <config node> configuration section. When shown, comments are enclosed with `/*` and `*/` as open/close delimiters. Comments need to be committed, just like other config changes.

To remove an existing comment from your current configuration, specify an empty string enclosed in double quote marks (`" "`) as the comment text.

Example:

```
vyos@vyos# comment firewall all-ping "Yes I know this VyOS is cool"
vyos@vyos# commit
vyos@vyos# show
firewall {
    /* Yes I know this VyOS is cool */
    all-ping enable
    broadcast-ping disable
    ...
}
```

Note: An important thing to note is that since the comment is added on top of the section, it will not appear if the `show <section>` command is used. With the above example, the `show firewall` command would return starting after the `firewall {` line, hiding the comment.

7.1.3 Access opmode from config mode

When inside configuration mode you are not directly able to execute operational commands.

run

Access to these commands are possible through the use of the `run [command]` command. From this command you will have access to everything accessible from operational mode.

Command completion and syntax help with `?` and `[tab]` will also work.

```
[edit]
vyos@vyos# run show interfaces
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
eth0           0.0.0.0/0       u/u
```

7.1.4 Managing configurations

VyOS comes with an integrated versioning system for the system configuration. It automatically maintains a backup of every previous configuration which has been committed to the system. The configurations are versioned locally for rollback but they can also be stored on a remote host for archiving/backup reasons.

Local Archive

Revisions are stored on disk. You can view, compare and rollback them to any previous revisions if something goes wrong.

show system commit

View all existing revisions on the local system.

```
vyos@vyos:~$ show system commit
0   2015-03-30 08:53:03 by vyos via cli
1   2015-03-30 08:52:20 by vyos via cli
2   2015-03-26 21:26:01 by root via boot-config-loader
3   2015-03-26 20:43:18 by root via boot-config-loader
4   2015-03-25 11:06:14 by root via boot-config-loader
5   2015-03-25 01:04:28 by root via boot-config-loader
6   2015-03-25 00:16:47 by vyos via cli
7   2015-03-24 23:43:45 by root via boot-config-loader
```

set system config-management commit-revisions <N>

You can specify the number of revisions stored on disk. `N` can be in the range of 0 - 65535. When the number of revisions exceeds the configured value, the oldest revision is removed. The default setting for this value is to store 100 revisions locally.

Compare configurations

VyOS lets you compare different configurations.

compare <saved | N> <M>

Use this command to spot what the differences are between different configurations.

```
vyos@vyos# compare [tab]
Possible completions:
<Enter>  Compare working & active configurations
```

(continues on next page)

(continued from previous page)

```

saved          Compare working & saved configurations
<N>           Compare working with revision N
<N> <M>       Compare revision N with M
Revisions:
  0           2013-12-17 20:01:37 root by boot-config-loader
  1           2013-12-13 15:59:31 root by boot-config-loader
  2           2013-12-12 21:56:22 vyos by cli
  3           2013-12-12 21:55:11 vyos by cli
  4           2013-12-12 21:27:54 vyos by cli
  5           2013-12-12 21:23:29 vyos by cli
  6           2013-12-12 21:13:59 root by boot-config-loader
  7           2013-12-12 16:25:19 vyos by cli
  8           2013-12-12 15:44:36 vyos by cli
  9           2013-12-12 15:42:07 root by boot-config-loader
 10          2013-12-12 15:42:06 root by init

```

The command `compare` allows you to compare different type of configurations. It also lets you compare different revisions through the `compare N M` command, where N and M are revision numbers. The output will describe how the configuration N is when compared to M indicating with a plus sign (+) the additional parts N has when compared to M, and indicating with a minus sign (-) the lacking parts N misses when compared to M.

```

vyos@vyos# compare 0 6
[edit interfaces]
+dummy dum1 {
+  address 10.189.0.1/31
+}
[edit interfaces ethernet eth0]
+vif 99 {
+  address 10.199.0.1/31
+}
-vif 900 {
-  address 192.0.2.4/24
-}

```

show system commit diff <number>

Show commit revision difference.

The command above also lets you see the difference between two commits. By default the difference with the running config is shown.

```

vyos@router# run show system commit diff 4
[edit system]
+ipv6 {
+  disable-forwarding
+}

```

This means four commits ago we did set `system ipv6 disable-forwarding`.

Rollback Changes

You can rollback configuration changes using the `rollback` command. This will apply the selected revision and trigger a system reboot.

rollback <N>

Rollback to revision N (currently requires reboot)

```
vyos@vyos# compare 1
[edit system]
>host-name vyos-1
[edit]

vyos@vyos# rollback 1
Proceed with reboot? [confirm][y]
Broadcast message from root@vyos-1 (pts/0) (Tue Dec 17 21:07:45 2013):
The system is going down for reboot NOW!
```

Remote Archive

VyOS can upload the configuration to a remote location after each call to `commit`. You will have to set the commit-archive location. TFTP, FTP, SCP and SFTP servers are supported. Every time a `commit` is successful the `config.boot` file will be copied to the defined destination(s). The filename used on the remote host will be `config.boot-hostname.YYYYMMDD_HHMMSS`.

set system config-management commit-archive location <URI>

Specify remote location of commit archive as any of the below URI (Uniform Resource Identifier)

- `scp://<user>:<passwd>@<host>:<dir>`
- `sftp://<user>:<passwd>@<host>:<dir>`
- `ftp://<user>:<passwd>@<host>:<dir>`
- `tftp://<host>:<dir>`

Note: The number of revisions don't affect the commit-archive.

Note: You may find VyOS not allowing the secure connection because it cannot verify the legitimacy of the remote server. You can use the workaround below to quickly add the remote host's SSH fingerprint to your `~/.ssh/known_hosts` file:

```
vyos@vyos# ssh-keyscan <host> >> ~/.ssh/known_hosts
```

Saving and loading manually

You can use the `save` and `load` commands if you want to manually manage specific configuration files.

When using the `save` command, you can add a specific location where to store your configuration file. And, when needed it, you will be able to load it with the `load` command:

load <URI>

Use this command to load a configuration which will replace the running configuration. Define the location of the configuration file to be loaded. You can use a path to a local file, an SCP address, an SFTP address, an FTP address, an HTTP address, an HTTPS address or a TFTP address.

```
vyos@vyos# load
Possible completions:
<Enter>                                Load from system config file
<file>                                Load from file on local machine
scp://<user>:<passwd>@<host>:<file>    Load from file on remote machine
sftp://<user>:<passwd>@<host>:<file>   Load from file on remote machine
ftp://<user>:<passwd>@<host>:<file>    Load from file on remote machine
http://<host>:<file>                  Load from file on remote machine
https://<host>:<file>                 Load from file on remote machine
tftp://<host>:<file>                  Load from file on remote machine
```

Restore Default

In the case you want to completely delete your configuration and restore the default one, you can enter the following command in configuration mode:

```
load /opt/vyatta/etc/config.boot.default
```

You will be asked if you want to continue. If you accept, you will have to use `commit` if you want to make the changes active.

Then you may want to `save` in order to delete the saved configuration too.

Note: If you are remotely connected, you will lose your connection. You may want to copy first the config, edit it to ensure connectivity, and load the edited config.

The following structure represent the cli structure.

8.1 Container

8.1.1 Configuration

set container <name>

Set a named container.

set container network <networkname>

Creates a named container network

set container registry <name>

Adds registry to list of unqualified-search-registries. By default, for any image that does not include the registry in the image name, Vyos will use docker.io as the container registry.

set container <name> image

Sets the image name in the hub registry

```
set container name mysql-server image mysql:8.0
```

If a registry is not specified, Docker.io will be used as the container registry unless an alternative registry is specified using **set container registry <name>** or the registry is included in the image name

```
set container name mysql-server image quay.io/mysql:8.0
```

set container <name> allow-host-networks

Allow host networking in a container. The network stack of the container is not isolated from the host and will use the host IP.

The following commands translate to “-net host” when the container is created

Note: `allow-host-networks` cannot be used with `network`

set container <name> description <text>

Sets the container description

set container <name> environment '<key>' value '<value>'

Add custom environment variables. Multiple environment variables are allowed. The following commands translate to “-e key=value” when the container is created.

```
set container name mysql-server environment 'MYSQL_DATABASE' value 'zabbix'
set container name mysql-server environment 'MYSQL_USER' value 'zabbix'
set container name mysql-server environment 'MYSQL_PASSWORD' value 'zabbix_pwd'
set container name mysql-server environment 'MYSQL_ROOT_PASSWORD' value 'root_pwd'
→ '
```

set container <name> network <networkname>

Attaches user-defined network to a container. Only one network must be specified and must already exist.

Optionally a specific static IPv4 or IPv6 address can be set for the container. This address must be within the named network.

```
set container <name> network <networkname> address <address>
```

Note: The first IP in the container network is reserved by the engine and cannot be used

set container <name> port <portname> [source | destination] <portnumber>

Publishes a port for the container

```
set container name zabbix-web-nginx-mysql port http source 80
set container name zabbix-web-nginx-mysql port http destination 8080
```

set container <name> volume <volumename> [source | destination] <path>

Mount a volume into the container

```
set container name coredns volume 'corefile' source /config/coredns/Corefile
set container name coredns volume 'corefile' destination /etc/Corefile
```

8.1.2 Example Configuration

For the sake of demonstration, [example #1 in the official documentation](#) to the declarative VyOS CLI syntax.

```
set container network zabbix-net prefix 172.20.0.0/16
set container network zabbix-net description 'Network for Zabbix component_
→containers'

set container name mysql-server image mysql:8.0
set container name mysql-server network zabbix-net
```

(continues on next page)

(continued from previous page)

```

set container name mysql-server environment 'MYSQL_DATABASE' value 'zabbix'
set container name mysql-server environment 'MYSQL_USER' value 'zabbix'
set container name mysql-server environment 'MYSQL_PASSWORD' value 'zabbix_
↪pwd'
set container name mysql-server environment 'MYSQL_ROOT_PASSWORD' value
↪'root_pwd'

set container name zabbix-java-gateway image zabbix/zabbix-java-
↪gateway:alpine-5.2-latest
set container name zabbix-java-gateway network zabbix-net

set container name zabbix-server-mysql image zabbix/zabbix-server-
↪mysql:alpine-5.2-latest
set container name zabbix-server-mysql network zabbix-net

set container name zabbix-server-mysql environment 'DB_SERVER_HOST' value
↪'mysql-server'
set container name zabbix-server-mysql environment 'MYSQL_DATABASE' value
↪'zabbix'
set container name zabbix-server-mysql environment 'MYSQL_USER' value 'zabbix
↪'
set container name zabbix-server-mysql environment 'MYSQL_PASSWORD' value
↪'zabbix_pwd'
set container name zabbix-server-mysql environment 'MYSQL_ROOT_PASSWORD' ↪
↪value 'root_pwd'
set container name zabbix-server-mysql environment 'ZBX_JAVAGATEWAY' value
↪'zabbix-java-gateway'

set container name zabbix-server-mysql port zabbix source 10051
set container name zabbix-server-mysql port zabbix destination 10051

set container name zabbix-web-nginx-mysql image zabbix/zabbix-web-nginx-
↪mysql:alpine-5.2-latest
set container name zabbix-web-nginx-mysql network zabbix-net

set container name zabbix-web-nginx-mysql environment 'MYSQL_DATABASE' value
↪'zabbix'
set container name zabbix-web-nginx-mysql environment 'ZBX_SERVER_HOST' ↪
↪value 'zabbix-server-mysql'
set container name zabbix-web-nginx-mysql environment 'DB_SERVER_HOST' value
↪'mysql-server'
set container name zabbix-web-nginx-mysql environment 'MYSQL_USER' value
↪'zabbix'
set container name zabbix-web-nginx-mysql environment 'MYSQL_PASSWORD' value
↪'zabbix_pwd'
set container name zabbix-web-nginx-mysql environment 'MYSQL_ROOT_PASSWORD' ↪
↪value 'root_pwd'

set container name zabbix-web-nginx-mysql port http source 80
set container name zabbix-web-nginx-mysql port http destination 8080

```

8.2 Firewall

8.2.1 Overview

VyOS makes use of Linux `netfilter` for packet filtering.

The firewall supports the creation of groups for ports, addresses, and networks (implemented using netfilter ipset) and the option of interface or zone based firewall policy.

Note: Important note on usage of terms: The firewall makes use of the terms *in*, *out*, and *local* for firewall policy. Users experienced with netfilter often confuse *in* to be a reference to the *INPUT* chain, and *out* the *OUTPUT* chain from netfilter. This is not the case. These instead indicate the use of the *FORWARD* chain and either the input or output interface. The *INPUT* chain, which is used for local traffic to the OS, is a reference to as *local* with respect to its input interface.

8.2.2 Global settings

Some firewall settings are global and have an affect on the whole system.

set firewall all-ping [enable | disable]

By default, when VyOS receives an ICMP echo request packet destined for itself, it will answer with an ICMP echo reply, unless you avoid it through its firewall.

With the firewall you can set rules to accept, drop or reject ICMP in, out or local traffic. You can also use the general **firewall all-ping** command. This command affects only to LOCAL (packets destined for your VyOS system), not to IN or OUT traffic.

Note: firewall all-ping affects only to LOCAL and it always behaves in the most restrictive way

```
set firewall all-ping enable
```

When the command above is set, VyOS will answer every ICMP echo request addressed to itself, but that will only happen if no other rule is applied dropping or rejecting local echo requests. In case of conflict, VyOS will not answer ICMP echo requests.

```
set firewall all-ping disable
```

When the command above is set, VyOS will answer no ICMP echo request addressed to itself at all, no matter where it comes from or whether more specific rules are being applied to accept them.

set firewall broadcast-ping [enable | disable]

This setting enable or disable the response of icmp broadcast messages. The following system parameter will be altered:

- `net.ipv4.icmp_echo_ignore_broadcasts`

set firewall ip-src-route [enable | disable]

set firewall ipv6-src-route [enable | disable]

This setting handle if VyOS accept packets with a source route option. The following system parameter will be altered:

- `net.ipv4.conf.all.accept_source_route`
- `net.ipv6.conf.all.accept_source_route`

set firewall receive-redirects [enable | disable]

set firewall ipv6-receive-redirects [enable | disable]

enable or disable of ICMPv4 or ICMPv6 redirect messages accepted by VyOS. The following system parameter will be altered:

- `net.ipv4.conf.all.accept_redirects`
- `net.ipv6.conf.all.accept_redirects`

set firewall send-redirects [enable | disable]

enable or disable ICMPv4 redirect messages send by VyOS The following system parameter will be altered:

- `net.ipv4.conf.all.send_redirects`

set firewall log-martians [enable | disable]

enable or disable the logging of martian IPv4 packets. The following system parameter will be altered:

- `net.ipv4.conf.all.log_martians`

set firewall source-validation [strict | loose | disable]

Set the IPv4 source validation mode. The following system parameter will be altered:

- `net.ipv4.conf.all.rp_filter`

set firewall syn-cookies [enable | disable]

Enable or Disable if VyOS use IPv4 TCP SYN Cookies. The following system parameter will be altered:

- `net.ipv4.tcp_syncookies`

set firewall twa-hazards-protection [enable | disable]

Enable or Disable VyOS to be [RFC 1337](#) conform. The following system parameter will be altered:

- `net.ipv4.tcp_rfc1337`

set firewall state-policy established action [accept | drop | reject]

set firewall state-policy established log enable

Set the global setting for an established connection.

set firewall state-policy invalid action [accept | drop | reject]

set firewall state-policy invalid log enable

Set the global setting for invalid packets.

set firewall state-policy related action [accept | drop | reject]

set firewall state-policy related log enable

Set the global setting for related connections.

8.2.3 Groups

Firewall groups represent collections of IP addresses, networks, or ports. Once created, a group can be referenced by firewall rules as either a source or destination. Members can be added or removed from a group without changes to, or the need to reload, individual firewall rules.

Note: Groups can also be referenced by NAT configuration.

Groups need to have unique names. Even though some contain IPv4 addresses and others contain IPv6 addresses, they still need to have unique names, so you may want to append “-v4” or “-v6” to your group names.

Address Groups

In an **address group** a single IP address or IP address ranges are defined.

```
set firewall group address-group <name> address [address | address range]
```

```
set firewall group ipv6-address-group <name> address <address>
```

Define a IPv4 or a IPv6 address group

```
set firewall group address-group ADR-INSIDE-v4 address 192.168.0.1
set firewall group address-group ADR-INSIDE-v4 address 10.0.0.1-10.0.0.8
set firewall group ipv6-address-group ADR-INSIDE-v6 address 2001:db8::1
```

```
set firewall group address-group <name> description <text>
```

```
set firewall group ipv6-address-group <name> description <text>
```

Provide a IPv4 or IPv6 address group description

Network Groups

While **network groups** accept IP networks in CIDR notation, specific IP addresses can be added as a 32-bit prefix. If you foresee the need to add a mix of addresses and networks, the network group is recommended.

```
set firewall group network-group <name> network <CIDR>
```

```
set firewall group ipv6-network-group <name> network <CIDR>
```

Define a IPv4 or IPv6 Network group.

```
set firewall group network-group NET-INSIDE-v4 network 192.168.0.0/24
set firewall group network-group NET-INSIDE-v4 network 192.168.1.0/24
set firewall group ipv6-network-group NET-INSIDE-v6 network 2001:db8::/64
```

```
set firewall group network-group <name> description <text>
```

```
set firewall group ipv6-network-group <name> description <text>
```

Provide a IPv4 or IPv6 network group description.

Port Groups

A **port group** represents only port numbers, not the protocol. Port groups can be referenced for either TCP or UDP. It is recommended that TCP and UDP groups are created separately to avoid accidentally filtering unnecessary ports. Ranges of ports can be specified by using -.

```
set firewall group port-group <name> port [portname | portnumber |
startport-endport]
```

Define a port group. A port name can be any name defined in /etc/services. e.g.: http

```
set firewall group port-group PORT-TCP-SERVER1 port http
set firewall group port-group PORT-TCP-SERVER1 port 443
set firewall group port-group PORT-TCP-SERVER1 port 5000-5010
```

```
set firewall group port-group <name> description <text>
```

Provide a port group description.

8.2.4 Rule-Sets

A rule-set is a named collection of firewall rules that can be applied to an interface or a zone. Each rule is numbered, has an action to apply if the rule is matched, and the ability to specify the criteria to match. Data packets go through the rules from 1 - 9999, at the first match the action of the rule will be executed.

```
set firewall name <name> description <text>
```

```
set firewall ipv6-name <name> description <text>
```

Provide a rule-set description.

```
set firewall name <name> default-action [drop | reject | accept]
```

```
set firewall ipv6-name <name> default-action [drop | reject | accept]
```

This set the default action of the rule-set if no rule matched a packet criteria.

```
set firewall name <name> enable-default-log
```

```
set firewall ipv6-name <name> enable-default-log
```

Use this command to enable the logging of the default action.

```
set firewall name <name> rule <1-9999> action [drop | reject | accept]
```

```
set firewall ipv6-name <name> rule <1-9999> action [drop | reject | accept]
```

This required setting defines the action of the current rule.

```
set firewall name <name> rule <1-9999> description <text>
```

```
set firewall ipv6-name <name> rule <1-9999> description <text>
```

Provide a description for each rule.

```
set firewall name <name> rule <1-9999> log [disable | enable]
```

```
set firewall ipv6-name <name> rule <1-9999> log [disable | enable]
```

Enable or disable logging for the matched packet.

```
set firewall name <name> rule <1-9999> disable
```

```
set firewall ipv6-name <name> rule <1-9999> disable
```

If you want to disable a rule but let it in the configuration.

Matching criteria

There are a lot of matching criteria against which the package can be tested.

```
set firewall name <name> rule <1-9999> source address [address | addressrange | CIDR]
```

```
set firewall name <name> rule <1-9999> destination address [address | addressrange | CIDR]
```

```
set firewall ipv6-name <name> rule <1-9999> source address [address | addressrange | CIDR]
```

```
set firewall ipv6-name <name> rule <1-9999> destination address [address | addressrange | CIDR]
```

This is similar to the network groups part, but here you are able to negate the matching addresses.

```
set firewall name WAN-IN-v4 rule 100 source address 192.0.2.10-192.0.2.11
# with a '!' the rule match everything except the specified subnet
set firewall name WAN-IN-v4 rule 101 source address !203.0.113.0/24
set firewall ipv6-name WAN-IN-v6 rule 100 source address 2001:db8::202
```

```
set firewall name <name> rule <1-9999> source mac-address <mac-address>
```

```
set firewall ipv6-name <name> rule <1-9999> source mac-address <mac-address>
```

Only in the source criteria, you can specify a mac-address.

```
set firewall name LAN-IN-v4 rule 100 source mac-address 00:53:00:11:22:33
set firewall name LAN-IN-v4 rule 101 source mac-address !00:53:00:aa:12:34
```

```
set firewall name <name> rule <1-9999> source port [1-65535 | portname | start-end]
```

```
set firewall name <name> rule <1-9999> destination port [1-65535 | portname | start-end]
```

```
set firewall ipv6-name <name> rule <1-9999> source port [1-65535 | portname | start-end]
```

```
set firewall ipv6-name <name> rule <1-9999> destination port [1-65535 | portname | start-end]
```

A port can be set with a port number or a name which is here defined: `/etc/services`.

```
set firewall name WAN-IN-v4 rule 10 source port '22'
set firewall name WAN-IN-v4 rule 11 source port '!http'
set firewall name WAN-IN-v4 rule 12 source port 'https'
```

Multiple source ports can be specified as a comma-separated list. The whole list can also be “negated” using ‘!’. For example:

```
set firewall ipv6-name WAN-IN-v6 rule 10 source port '!22,https,3333-3338'
```

```
set firewall name <name> rule <1-9999> source group address-group <name>
```

```
set firewall name <name> rule <1-9999> destination group address-group <name>
```

```
set firewall ipv6-name <name> rule <1-9999> source group address-group <name>
```

```
set firewall ipv6-name <name> rule <1-9999> destination group address-group <name>
```

Use a specific address-group

```
set firewall name <name> rule <1-9999> source group network-group <name>
set firewall name <name> rule <1-9999> destination group network-group <name>
set firewall ipv6-name <name> rule <1-9999> source group network-group <name>
set firewall ipv6-name <name> rule <1-9999> destination group network-group <name>
```

Use a specific network-group

```
set firewall name <name> rule <1-9999> source group port-group <name>
set firewall name <name> rule <1-9999> destination group port-group <name>
set firewall ipv6-name <name> rule <1-9999> source group port-group <name>
set firewall ipv6-name <name> rule <1-9999> destination group port-group <name>
```

Use a specific port-group

```
set firewall name <name> rule <1-9999> protocol [<text> | <0-255> | all |
tcp_udp]
set firewall ipv6-name <name> rule <1-9999> protocol [<text> | <0-255> | all |
tcp_udp]
```

Match a protocol criteria. A protocol number or a name which is here defined: `/etc/protocols`. Special names are `all` for all protocols and `tcp_udp` for tcp and udp based packets. The `!` negate the selected protocol.

```
set firewall name WAN-IN-v4 rule 10 protocol tcp_udp
set firewall name WAN-IN-v4 rule 11 protocol !tcp_udp
set firewall ipv6-name WAN-IN-v6 rule 10 protocol tcp
```

```
set firewall name <name> rule <1-9999> tcp flags <text>
```

```
set firewall ipv6-name <name> rule <1-9999> tcp flags <text>
```

Allowed values for TCP flags: SYN, ACK, FIN, RST, URG, PSH, ALL. When specifying more than one flag, flags should be comma separated. The `!` negate the selected protocol.

```
set firewall name WAN-IN-v4 rule 10 tcp flags 'ACK'
set firewall name WAN-IN-v4 rule 12 tcp flags 'SYN'
set firewall name WAN-IN-v4 rule 13 tcp flags 'SYN,!ACK,!FIN,!RST'
```

```
set firewall name <name> rule <1-9999> state [established | invalid | new |
related] [enable | disable]
```

```
set firewall ipv6-name <name> rule <1-9999> state [established | invalid | new
| related] [enable | disable]
```

Match against the state of a packet.

8.2.5 Applying a Rule-Set to an Interface

A Rule-Set can be applied to every interface:

- `in`: Ruleset for forwarded packets on an inbound interface

- `out`: Ruleset for forwarded packets on an outbound interface
- `local`: Ruleset for packets destined for this router

```
set interface ethernet <ethN> firewall [in | out | local] [name | ipv6-name]
<rule-set>
```

Here are some examples for applying a rule-set to an interface

```
set interface ethernet eth1 vif 100 firewall in name LANv4-IN
set interface ethernet eth1 vif 100 firewall out name LANv4-OUT
set interface bonding bond0 firewall in name LANv4-IN
set interfaces openvpn vtun1 firewall in name Lanv4-IN
```

Note: As you can see in the example here, you can assign the same rule-set to several interfaces. An interface can only have one rule-set per chain.

8.2.6 Zone-based Firewall Policy

As an alternative to applying policy to an interface directly, a zone-based firewall can be created to simplify configuration when multiple interfaces belong to the same security zone. Instead of applying rule-sets to interfaces, they are applied to source zone-destination zone pairs.

An basic introduction to zone-based firewalls can be found [here](#), and an example at *Zone-Policy example*.

Define a Zone

To define a zone setup either one with interfaces or a local zone.

```
set zone-policy zone <name> interface <interfacenames>
```

Set interfaces to a zone. A zone can have multiple interfaces. But an interface can only be a member in one zone.

```
set zone-policy zone <name> local-zone
```

Define the zone as a local zone. A local zone has no interfaces and will be applied to the router itself.

```
set zone-policy zone <name> default-action [drop | reject]
```

Change the default-action with this setting.

```
set zone-policy zone <name> description
```

Set a meaningful description.

Applying a Rule-Set to a Zone

Before you are able to apply a rule-set to a zone you have to create the zones first.

```
set zone-policy zone <name> from <name> firewall name <rule-set>
```

```
set zone-policy zone <name> from <name> firewall ipv6-name <rule-set>
```

You apply a rule-set always to a zone from an other zone, it is recommended to create one rule-set for each zone pair.

```
set zone-policy zone DMZ from LAN firewall name LANv4-to-DMZv4
set zone-policy zone LAN from DMZ firewall name DMZv4-to-LANv4
```

8.2.7 Operation-mode Firewall

Rule-set overview

show firewall

This will show you a basic firewall overview

```
vyos@vyos:~$ show firewall

-----
Firewall Global Settings
-----

Firewall state-policy for all IPv4 and Ipv6 traffic

show firewall statistics

This will show you a statistic of all rule-sets since the last boot.

show firewall [name | ipv6name] <name> rule <1-9999>

This command will give an overview of a rule in a single rule-set

show firewall group <name>

Overview of defined groups. You see the type, the members, and where the group is used.

```

vyos@vyos:~$ show firewall group DMZ-Ports
Name      : DMZ-Ports
Type      : port
References : none
Members   :
           80
           443
           8080
           8443

vyos@vyos:~$ show firewall group LANv4
Name      : LANv4
Type      : network
References : LANv4-IN-10-source
Members   :
           10.10.0.0/16

```

show firewall [name | ipv6name] <name>

This command will give an overview of a single rule-set.

show firewall [name | ipv6name] <name> statistics

This will show you a rule-set statistic since the last boot.

show firewall [name | ipv6name] <name> rule <1-9999>

This command will give an overview of a rule in a single rule-set.

Zone-Policy Overview

show zone-policy zone <name>

Use this command to get an overview of a zone.

```

vyos@vyos:~$ show zone-policy zone DMZ
-----
Name: DMZ

Interfaces: eth0 eth1

From Zone:

```

(continues on next page)

(continued from previous page)

name	firewall
----	-----
LAN	DMZv4-1-OUT

Show Firewall log

show log firewall [name | ipv6name] <name>

Show the logs of a specific Rule-Set.

Note: At the moment it not possible to look at the whole firewall log with VyOS operational commands. All logs will save to /var/logs/messages. For example: `grep '10.10.0.10' /var/log/messages`

Example Partial Config

```
firewall {
  all-ping enable
  broadcast-ping disable
  config-trap disable
  group {
    network-group BAD-NETWORKS {
      network 198.51.100.0/24
      network 203.0.113.0/24
    }
    network-group GOOD-NETWORKS {
      network 192.0.2.0/24
    }
    port-group BAD-PORTS {
      port 65535
    }
  }
  name FROM-INTERNET {
    default-action accept
    description "From the Internet"
    rule 10 {
      action accept
      description "Authorized Networks"
      protocol all
      source {
        group {
          network-group GOOD-NETWORKS
        }
      }
    }
    rule 11 {
      action drop
      description "Bad Networks"
      protocol all
      source {
        group {
          network-group BAD-NETWORKS
        }
      }
    }
  }
}
```

(continues on next page)

(continued from previous page)

```

    }
  }
  rule 30 {
    action drop
    description "BAD PORTS"
    destination {
      group {
        port-group BAD-PORTS
      }
    }
    log enable
    protocol all
  }
}
interfaces {
  ethernet eth1 {
    address dhcp
    description OUTSIDE
    duplex auto
    firewall {
      in {
        name FROM-INTERNET
      }
    }
  }
}

```

8.2.8 TCP-MSS Clamping

As Internet wide PMTU discovery rarely works, we sometimes need to clamp our TCP MSS value to a specific value. This is a field in the TCP Options part of a SYN packet. By setting the MSS value, you are telling the remote side unequivocally 'do not try to send me packets bigger than this value'.

Starting with VyOS 1.2 there is a firewall option to clamp your TCP MSS value for IPv4 and IPv6.

Note: MSS value = MTU - 20 (IP header) - 20 (TCP header), resulting in 1452 bytes on a 1492 byte MTU.

IPv4

set firewall options interface <interface> adjust-mss <number-of-bytes>

Use this command to set the maximum segment size for IPv4 transit packets on a specific interface (500-1460 bytes).

Example

Clamp outgoing MSS value in a TCP SYN packet to *1452* for *pppoe0* and *1372* for your WireGuard *wg02* tunnel.

```

set firewall options interface pppoe0 adjust-mss '1452'
set firewall options interface wg02 adjust-mss '1372'

```

IPv6

set firewall options interface <interface> adjust-mss6 <number-of-bytes>

Use this command to set the maximum segment size for IPv6 transit packets on a specific interface (1280-1492 bytes).

Example

Clamp outgoing MSS value in a TCP SYN packet to *1280* for both *pppoe0* and *wg02* interface.

```
set firewall options interface pppoe0 adjust-mss6 '1280'
set firewall options interface wg02 adjust-mss6 '1280'
```

Hint: When doing your byte calculations, you might find useful this [Visual packet size calculator](#).

8.3 High availability

VRRP (Virtual Router Redundancy Protocol) provides active/backup redundancy for routers. Every VRRP router has a physical IP/IPv6 address, and a virtual address. On startup, routers elect the master, and the router with the highest priority becomes the master and assigns the virtual address to its interface. All routers with lower priorities become backup routers. The master then starts sending keepalive packets to notify other routers that it's available. If the master fails and stops sending keepalive packets, the router with the next highest priority becomes the new master and takes over the virtual address.

VRRP keepalive packets use multicast, and VRRP setups are limited to a single datalink layer segment. You can setup multiple VRRP groups (also called virtual routers). Virtual routers are identified by a VRID (Virtual Router Identifier). If you setup multiple groups on the same interface, their VRIDs must be unique, but it's possible (even if not recommended for readability reasons) to use duplicate VRIDs on different interfaces.

8.3.1 Basic setup

VRRP groups are created with the `set high-availability vrrp group $GROUP_NAME` commands. The required parameters are `interface`, `vrid`, and `virtual-address`.

minimal config

```
set high-availability vrrp group Foo vrid 10
set high-availability vrrp group Foo interface eth0
set high-availability vrrp group Foo virtual-address 192.0.2.1/24
```

You can verify your VRRP group status with the operational mode `run show vrrp` command:

```
vyos@vyos# run show vrrp
Name      Interface      VRID  State      Last Transition
-----
Foo       eth1            10    MASTER     2s
```

8.3.2 IPv6 support

The `virtual-address` parameter can be either an IPv4 or IPv6 address, but you cannot mix IPv4 and IPv6 in the same group, and will need to create groups with different VRIDs specially for IPv4 and IPv6.

8.3.3 Disabling a VRRP group

You can disable a VRRP group with `disable` option:

```
set high-availability vrrp group Foo disable
```

A disabled group will be removed from the VRRP process and your router will not participate in VRRP for that VRID. It will disappear from operational mode commands output, rather than enter the backup state.

8.3.4 Setting VRRP group priority

VRRP priority can be set with `priority` option:

```
set high-availability vrrp group Foo priority 200
```

The priority must be an integer number from 1 to 255. Higher priority value increases router's precedence in the master elections.

8.3.5 Sync groups

A sync group allows VRRP groups to transition together.

```
edit high-availability vrrp
set sync-group MAIN member VLAN9
set sync-group MAIN member VLAN20
```

In the following example, when VLAN9 transitions, VLAN20 will also transition:

```
vrrp {
  group VLAN9 {
    interface eth0.9
    virtual-address 10.9.1.1/24
    priority 200
    vrid 9
  }
  group VLAN20 {
    interface eth0.20
    priority 200
    virtual-address 10.20.20.1/24
    vrid 20
  }
  sync-group MAIN {
    member VLAN20
    member VLAN9
  }
}
```

Warning: All items in a sync group should be similarly configured. If one VRRP group is set to a different preemption delay or priority, it would result in an endless transition loop.

8.3.6 Preemption

VRRP can use two modes: preemptive and non-preemptive. In the preemptive mode, if a router with a higher priority fails and then comes back, routers with lower priority will give up their master status. In non-preemptive mode, the newly elected master will keep the master status and the virtual address indefinitely.

By default VRRP uses preemption. You can disable it with the “no-preempt” option:

```
set high-availability vrrp group Foo no-preempt
```

You can also configure the time interval for preemption with the “preempt-delay” option. For example, to set the higher priority router to take over in 180 seconds, use:

```
set high-availability vrrp group Foo preempt-delay 180
```

8.3.7 Unicast VRRP

By default VRRP uses multicast packets. If your network does not support multicast for whatever reason, you can make VRRP use unicast communication instead.

```
set high-availability vrrp group Foo peer-address 192.0.2.10
set high-availability vrrp group Foo hello-source-address 192.0.2.15
```

8.3.8 rfc3768-compatibility

RFC 3768 defines a virtual MAC address to each VRRP virtual router. This virtual router MAC address will be used as the source in all periodic VRRP messages sent by the active node. When the rfc3768-compatibility option is set, a new VRRP interface is created, to which the MAC address and the virtual IP address is automatically assigned.

```
set high-availability vrrp group Foo rfc3768-compatibility
```

Verification

```
$show interfaces ethernet eth0v10
eth0v10@eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue
state UP group default qlen 1000
link/ether 00:00:5e:00:01:0a brd ff:ff:ff:ff:ff:ff
inet 172.25.0.247/16 scope global eth0v10
valid_lft forever preferred_lft forever
```

8.3.9 Scripting

VRRP functionality can be extended with scripts. VyOS supports two kinds of scripts: health check scripts and transition scripts. Health check scripts execute custom checks in addition to the master router reachability. Transition scripts are executed when VRRP state changes from master to backup or fault and vice versa and can be used to enable or disable certain services, for example.

Health check scripts

This setup will make the VRRP process execute the `/config/scripts/vrrp-check.sh` script every 60 seconds, and transition the group to the fault state if it fails (i.e. exits with non-zero status) three times:

```
set high-availability vrrp group Foo health-check script /config/scripts/vrrp-check.sh
set high-availability vrrp group Foo health-check interval 60
set high-availability vrrp group Foo health-check failure-count 3
```

Transition scripts

Transition scripts can help you implement various fixups, such as starting and stopping services, or even modifying the VyOS config on VRRP transition. This setup will make the VRRP process execute the `/config/scripts/vrrp-fail.sh` with argument `Foo` when VRRP fails, and the `/config/scripts/vrrp-master.sh` when the router becomes the master:

```
set high-availability vrrp group Foo transition-script backup "/config/scripts/vrrp-
↪fail.sh Foo"
set high-availability vrrp group Foo transition-script fault "/config/scripts/vrrp-
↪fail.sh Foo"
set high-availability vrrp group Foo transition-script master "/config/scripts/vrrp-
↪master.sh Foo"
```

To know more about scripting, check the [Command Scripting](#) section.

8.4 Interfaces

8.4.1 Bond / Link Aggregation

The bonding interface provides a method for aggregating multiple network interfaces into a single logical “bonded” interface, or LAG, or ether-channel, or port-channel. The behavior of the bonded interfaces depends upon the mode; generally speaking, modes provide either hot standby or load balancing services. Additionally, link integrity monitoring may be performed.

Configuration

Common interface configuration

```
set interfaces bond <interface> address <address | dhcp | dhcpv6>
```

Configure interface *<interface>* with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces bond bond0 address 192.0.2.1/24
set interfaces bond bond0 address 2001:db8::1/64
set interfaces bond bond0 address dhcp
set interfaces bond bond0 address dhcpv6
```

set interfaces bond <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bond bond0 description 'This is an awesome interface running on
↳VyOS'
```

set interfaces bond <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bond bond0 disable
```

set interfaces bond <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces bond bond0 disable-flow-control
```

set interfaces bond <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces bond bond0 disable-link-detect
```

set interfaces bond <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC (Media Access Control) address on given <interface>.

Example:

```
set interfaces bond bond0 mac '00:01:02:03:04:05'
```

set interfaces bond <interface> mtu <mtu>

Configure MTU (Maximum Transmission Unit) on given *<interface>*. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bond bond0 mtu 9000
```

set interfaces bond <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bond bond0 ip arp-cache-timeout 180
```

set interfaces bond <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bond bond0 ip disable-arp-filter
```

set interfaces bond <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bond bond0 ip disable-forwarding
```

set interfaces bond <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bond bond0 ip enable-arp-accept
```

set interfaces bond <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part

of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bond bond0 ip enable-arp-announce
```

set interfaces bond <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bond bond0 ip enable-arp-ignore
```

set interfaces bond <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bond bond0 ip enable-proxy-arp
```

set interfaces bond <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces bond <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.

- disable: No source validation

set interfaces bond <interface> ipv6 address autoconf

SLAAC (Stateless Address Autoconfiguration) [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 (Internet Control Message Protocol version 6) router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces bond bond0 ipv6 address autoconf
```

set interfaces bond <interface> ipv6 address eui64 <prefix>

EUI-64 (64-Bit Extended Unique Identifier) as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bond bond0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces bond <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bond bond0 ipv6 address no-default-link-local
```

set interfaces bond <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bond bond0 ipv6 disable-forwarding
```

set interfaces bond <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bond bond0 vrf red
```

DHCP(v6)

set interfaces bond <interface> dhcp-options client-id <description>

[RFC 2131](#) states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bond bond0 dhcp-options client-id 'foo-bar'
```

set interfaces bond <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bond bond0 dhcp-options host-name 'VyOS'
```

set interfaces bond <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bond bond0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces bond <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bond bond0 dhcp-options no-default-route
```

set interfaces bond <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bond bond0 dhcp-options default-route-distance 220
```

set interfaces bond <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bond bond0 dhcp-options reject 192.168.100.0/24
```

set interfaces bond <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bond bond0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces bond <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bond bond0 dhcpv6-options parameters-only
```

set interfaces bond <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bond bond0 dhcpv6-options rapid-commit
```

set interfaces bond <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bond bond0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces bond <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bond bond0 dhcpv6-options pd 0 length 56
```

set interfaces bond <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bond bond0 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces bond <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bond bond0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Member Interfaces

```
set interfaces bonding <interface> member interface <member>
```

Enslave <member> interface to bond <interface>.

Bond options

```
set interfaces bonding <interface> mode <802.3ad | active-backup | broadcast |  
round-robin | transmit-load-balance | adaptive-load-balance | xor-hash>
```

Specifies one of the bonding policies. The default is 802.3ad. Possible values are:

- **802.3ad** - IEEE 802.3ad Dynamic link aggregation. Creates aggregation groups that share the same speed and duplex settings. Utilizes all slaves in the active aggregator according to the 802.3ad specification.

Slave selection for outgoing traffic is done according to the transmit hash policy, which may be changed from the default simple XOR policy via the `hash-policy` option, documented below.

Note: Not all transmit policies may be 802.3ad compliant, particularly in regards to the packet misordering requirements of section 43.2.4 of the 802.3ad standard.

- **active-backup** - Active-backup policy: Only one slave in the bond is active. A different slave becomes active if, and only if, the active slave fails. The bond's MAC address is externally visible on only one port (network adapter) to avoid confusing the switch.

When a failover occurs in active-backup mode, bonding will issue one or more gratuitous ARPs on the newly active slave. One gratuitous ARP is issued for the bonding master interface and each VLAN interfaces configured above it, provided that the interface has at least one IP address configured. Gratuitous ARPs issued for VLAN interfaces are tagged with the appropriate VLAN id.

This mode provides fault tolerance. The `primary` option, documented below, affects the behavior of this mode.

- **broadcast** - Broadcast policy: transmits everything on all slave interfaces.

This mode provides fault tolerance.

- **round-robin** - Round-robin policy: Transmit packets in sequential order from the first available slave through the last.

This mode provides load balancing and fault tolerance.

- **transmit-load-balance** - Adaptive transmit load balancing: channel bonding that does not require any special switch support.

Incoming traffic is received by the current slave. If the receiving slave fails, another slave takes over the MAC address of the failed receiving slave.

- **adaptive-load-balance** - Adaptive load balancing: includes transmit-load-balance plus receive load balancing for IPv4 traffic, and does not require any special switch support. The receive load balancing is achieved by ARP negotiation. The bonding driver intercepts the ARP Replies sent by the local system on their way out and overwrites the source hardware address with the unique hardware address of one of the slaves in the bond such that different peers use different hardware addresses for the server.

Receive traffic from connections created by the server is also balanced. When the local system sends an ARP Request the bonding driver copies and saves the peer's IP information from the ARP packet. When the ARP Reply arrives from the peer, its hardware address is retrieved and the bonding driver initiates an ARP reply to this peer assigning it to one of the slaves in the bond. A problematic outcome of using ARP negotiation for balancing is that each time that an ARP request is broadcast it uses the hardware address of the bond. Hence, peers learn the hardware address of the bond and the balancing of receive traffic collapses to the current slave. This is handled by sending updates (ARP Replies) to all the peers with their individually assigned hardware address such that the traffic is redistributed. Receive traffic is also redistributed when a new slave is added to the bond and when an inactive slave is re-activated. The receive load is distributed sequentially (round robin) among the group of highest speed slaves in the bond.

When a link is reconnected or a new slave joins the bond the receive traffic is redistributed among all active slaves in the bond by initiating ARP Replies with the selected MAC address to each of the clients. The updelay parameter (detailed below) must be set to a value equal or greater than the switch's forwarding delay so that the ARP Replies sent to the peers will not be blocked by the switch.

- **xor-hash** - XOR policy: Transmit based on the selected transmit hash policy. The default policy is a simple [(source MAC address XOR'd with destination MAC address XOR packet type ID) modulo slave count]. Alternate transmit policies may be selected via the `hash-policy` option, described below.

This mode provides load balancing and fault tolerance.

set interfaces bonding <interface> min-links <0-16>

Specifies the minimum number of links that must be active before asserting carrier. It is similar to the Cisco EtherChannel min-links feature. This allows setting the minimum number of member ports that must be up (link-up state) before marking the bond device as up (carrier on). This is useful for situations where higher level services such as clustering want to ensure a minimum number of low bandwidth links are active before switchover.

This option only affects 802.3ad mode.

The default value is 0. This will cause the carrier to be asserted (for 802.3ad mode) whenever there is an active aggregator, regardless of the number of available links in that aggregator.

Note: Because an aggregator cannot be active without at least one available link, setting this option to 0 or to 1 has the exact same effect.

set interfaces bonding <interface> lacp-rate <slow|fast>

Option specifying the rate in which we'll ask our link partner to transmit LACPDUs in 802.3ad mode.

This option only affects 802.3ad mode.

- **slow:** Request partner to transmit LACPDUs every 30 seconds
- **fast:** Request partner to transmit LACPDUs every 1 second

The default value is slow.

set interfaces bonding <interface> hash-policy <policy>

- **layer2** - Uses XOR of hardware MAC addresses and packet type ID field to generate the hash. The formula is

```
hash = source MAC XOR destination MAC XOR packet type ID
slave number = hash modulo slave count
```

This algorithm will place all traffic to a particular network peer on the same slave.

This algorithm is 802.3ad compliant.

- **layer2+3** - This policy uses a combination of layer2 and layer3 protocol information to generate the hash. Uses XOR of hardware MAC addresses and IP addresses to generate the hash. The formula is:

```
hash = source MAC XOR destination MAC XOR packet type ID
hash = hash XOR source IP XOR destination IP
hash = hash XOR (hash RSHIFT 16)
hash = hash XOR (hash RSHIFT 8)
```

And then hash is reduced modulo slave count.

If the protocol is IPv6 then the source and destination addresses are first hashed using `ipv6_addr_hash`.

This algorithm will place all traffic to a particular network peer on the same slave. For non-IP traffic, the formula is the same as for the layer2 transmit hash policy.

This policy is intended to provide a more balanced distribution of traffic than layer2 alone, especially in environments where a layer3 gateway device is required to reach most destinations.

This algorithm is 802.3ad compliant.

- **layer3+4** - This policy uses upper layer protocol information, when available, to generate the hash. This allows for traffic to a particular network peer to span multiple slaves, although a single connection will not span multiple slaves.

The formula for unfragmented TCP and UDP packets is

```
hash = source port, destination port (as in the header)
hash = hash XOR source IP XOR destination IP
hash = hash XOR (hash RSHIFT 16)
hash = hash XOR (hash RSHIFT 8)
```

And then hash is reduced modulo slave count.

If the protocol is IPv6 then the source and destination addresses are first hashed using `ipv6_addr_hash`.

For fragmented TCP or UDP packets and all other IPv4 and IPv6 protocol traffic, the source and destination port information is omitted. For non-IP traffic, the formula is the same as for the layer2 transmit hash policy.

This algorithm is not fully 802.3ad compliant. A single TCP or UDP conversation containing both fragmented and unfragmented packets will see packets striped across two interfaces. This may result in out of order delivery. Most traffic types will not meet these criteria, as TCP rarely fragments traffic, and most UDP traffic is not involved in extended conversations. Other implementations of 802.3ad may or may not tolerate this noncompliance.

set interfaces bonding <interface> primary <interface>

An *<interface>* specifying which slave is the primary device. The specified device will always be the active slave while it is available. Only when the primary is off-line will alternate devices be used. This is useful when one slave is preferred over another, e.g., when one slave has higher throughput than another.

The primary option is only valid for active-backup, transmit-load-balance, and adaptive-load-balance mode.

set interfaces bonding <interface> arp-monitor interval <time>

Specifies the ARP link monitoring *<time>* in seconds.

The ARP monitor works by periodically checking the slave devices to determine whether they have sent or received traffic recently (the precise criteria depends upon the bonding mode, and the state of the slave). Regular traffic is generated via ARP probes issued for the addresses specified by the `arp-monitor target` option.

If ARP monitoring is used in an etherchannel compatible mode (modes round-robin and xor-hash), the switch should be configured in a mode that evenly distributes packets across all links. If the switch is configured to distribute the packets in an XOR fashion, all replies from the ARP targets will be received on the same link which could cause the other team members to fail.

A value of 0 disables ARP monitoring. The default value is 0.

set interfaces bonding <interface> arp-monitor target <address>

Specifies the IP addresses to use as ARP monitoring peers when `arp-monitor interval` option is `> 0`. These are the targets of the ARP request sent to determine the health of the link to the targets.

Multiple target IP addresses can be specified. At least one IP address must be given for ARP monitoring to function.

The maximum number of targets that can be specified is 16. The default value is no IP address.

Offloading

set interfaces bonding <interface> xdp

Enable support for Linux XDP (eXpress Data Path) on recent 1.4 rolling releases. You must enable it for every interface which should participate in the XDP forwarding.

XDP is an eBPF based high performance data path merged in the Linux kernel since version 4.8. The idea behind XDP is to add an early hook in the RX path of the kernel, and let a user supplied eBPF program decide the fate of the packet. The hook is placed in the NIC driver just after the interrupt processing, and before any memory allocation needed by the network stack itself, because memory allocation can be an expensive operation.

Warning: This is highly experimental!

Note: Enabling this feature will break any form of NAT or Firewalling on this interface, as XDP is handled way earlier in the driver than iptables/ nftables.

Enabling this feature will only load the XDP router code as described here:

<https://blog.apnic.net/2020/04/30/how-to-build-an-xdp-based-bgp-peering-router/>

Example:

```
set interfaces bonding bond0 xdp
```

VLAN

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame

must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

set interfaces bond <interface> vif <vlan-id>

Create a new VLAN interface on interface <interface> using the VLAN number provided via <vlan-id>.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

Note: Only 802.1Q-tagged packets are accepted on Ethernet vifs.

set interfaces bond <interface> vif <vlan-id> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces bond bond0 vif 10 address 192.0.2.1/24
set interfaces bond bond0 vif 10 address 2001:db8::1/64
set interfaces bond bond0 vif 10 address dhcp
set interfaces bond bond0 vif 10 address dhcpv6
```

set interfaces bond <interface> vif <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bond bond0 vif 10 description 'This is an awesome interface_
↳running on VyOS'
```

set interfaces bond <interface> vif <vlan-id> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bond bond0 vif 10 disable
```

set interfaces bond <interface> vif <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces bond bond0 vif 10 disable-link-detect
```

set interfaces bond <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces bond bond0 vif 10 mac '00:01:02:03:04:05'
```

set interfaces bond <interface> vif <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bond bond0 vif 10 mtu 9000
```

set interfaces bond <interface> vif <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bond bond0 vif 10 ip arp-cache-timeout 180
```

set interfaces bond <interface> vif <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bond bond0 vif 10 ip disable-arp-filter
```

set interfaces bond <interface> vif <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bond bond0 vif 10 ip disable-forwarding
```

set interfaces bond <interface> vif <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bond bond0 vif 10 ip enable-arp-accept
```

set interfaces bond <interface> vif <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bond bond0 vif 10 ip enable-arp-announce
```

set interfaces bond <interface> vif <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bond bond0 vif 10 ip enable-arp-ignore
```

set interfaces bond <interface> vif <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bond bond0 vif 10 ip enable-proxy-arp
```

set interfaces bond <interface> vif <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces bond <interface> vif <vlan-id> ip source-validation <strict | loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces bond <interface> vif <vlan-id> ipv6 address autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces bond bond0 vif 10 ipv6 address autoconf
```

```
set interfaces bond <interface> vif <vlan-id> ipv6 address eui64 <prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bond bond0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

```
set interfaces bond <interface> vif <vlan-id> ipv6 address no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bond bond0 vif 10 ipv6 address no-default-link-local
```

```
set interfaces bond <interface> vif <vlan-id> ipv6 disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bond bond0 vif 10 ipv6 disable-forwarding
```

```
set interfaces bond <interface> vif <vlan-id> vrf <vrf>
```

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bond bond0 vif 10 vrf red
```

DHCP(v6)

set interfaces bond <interface> vif <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the 'client identifier' option. If the client supplies a 'client identifier', the client MUST use the same 'client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bond bond0 vif 10 dhcp-options client-id 'foo-bar'
```

set interfaces bond <interface> vif <vlan-id> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bond bond0 vif 10 dhcp-options host-name 'VyOS'
```

set interfaces bond <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bond bond0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

set interfaces bond <interface> vif <vlan-id> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bond bond0 vif 10 dhcp-options no-default-route
```

set interfaces bond <interface> vif <vlan-id> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bond bond0 vif 10 dhcp-options default-route-distance 220
```

set interfaces bond <interface> vif <vlan-id> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bond bond0 vif 10 dhcp-options reject 192.168.100.0/24
```

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options duid <duid>
```

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bond bond0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options parameters-only
```

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bond bond0 vif 10 dhcpv6-options parameters-only
```

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options rapid-commit
```

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bond bond0 vif 10 dhcpv6-options rapid-commit
```

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options temporary
```

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bond bond0 vif 10 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bond bond0 vif 10 dhcpv6-options pd 0 length 56
```

```
set interfaces bond <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bond bond0 vif 10 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces bond <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bond bond0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

set interfaces bonding <interface> mirror ingress <monitor-interface>

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *bond1* port to *eth3*

```
set interfaces bonding bond1 mirror ingress eth3
```

set interfaces bonding <interface> mirror egress <monitor-interface>

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *bond1* port to *eth3*

```
set interfaces bonding bond1 mirror egress eth3
```

Example

The following configuration on VyOS applies to all following 3rd party vendors. It creates a bond with two links and VLAN 10, 100 on the bonded interfaces with a per VIF IPv4 address.

```
# Create bonding interface bond0 with 802.3ad LACP
set interfaces bonding bond0 hash-policy 'layer2'
set interfaces bonding bond0 mode '802.3ad'

# Add the required vlans and IPv4 addresses on them
set interfaces bonding bond0 vif 10 address 192.168.0.1/24
set interfaces bonding bond0 vif 100 address 10.10.10.1/24

# Add the member interfaces to the bonding interface
set interfaces bonding bond0 member interface eth1
set interfaces bonding bond0 member interface eth2
```

Cisco Catalyst

Assign member interfaces to PortChannel

```
interface GigabitEthernet1/0/23
description VyOS eth1
channel-group 1 mode active
!
interface GigabitEthernet1/0/24
description VyOS eth2
channel-group 1 mode active
!
```

A new interface becomes present Port-channel1, all configuration like allowed VLAN interfaces, STP will happen here.

```
interface Port-channel1
description LACP Channel for VyOS
switchport trunk encapsulation dot1q
switchport trunk allowed vlan 10,100
switchport mode trunk
spanning-tree portfast trunk
!
```

Juniper EX Switch

For a headstart you can use the below example on how to build a bond with two interfaces from VyOS to a Juniper EX Switch system.

```
# Create aggregated ethernet device with 802.3ad LACP and port speeds of 10gbit/s
set interfaces ae0 aggregated-ether-options link-speed 10g
set interfaces ae0 aggregated-ether-options lacp active

# Create layer 2 on the aggregated ethernet device with trunking for our vlans
set interfaces ae0 unit 0 family ethernet-switching port-mode trunk

# Add the required vlans to the device
set interfaces ae0 unit 0 family ethernet-switching vlan members 10
set interfaces ae0 unit 0 family ethernet-switching vlan members 100

# Add the two interfaces to the aggregated ethernet device, in this setup both
# ports are on the same switch (switch 0, module 1, port 0 and 1)
set interfaces xe-0/1/0 ether-options 802.3ad ae0
set interfaces xe-0/1/1 ether-options 802.3ad ae0

# But this can also be done with multiple switches in a stack, a virtual
# chassis on Juniper (switch 0 and switch 1, module 1, port 0 on both switches)
set interfaces xe-0/1/0 ether-options 802.3ad ae0
set interfaces xe-1/1/0 ether-options 802.3ad ae0
```

Aruba/HP

For a headstart you can use the below example on how to build a bond, port-channel with two interfaces from VyOS to a Aruba/HP 2510G switch.

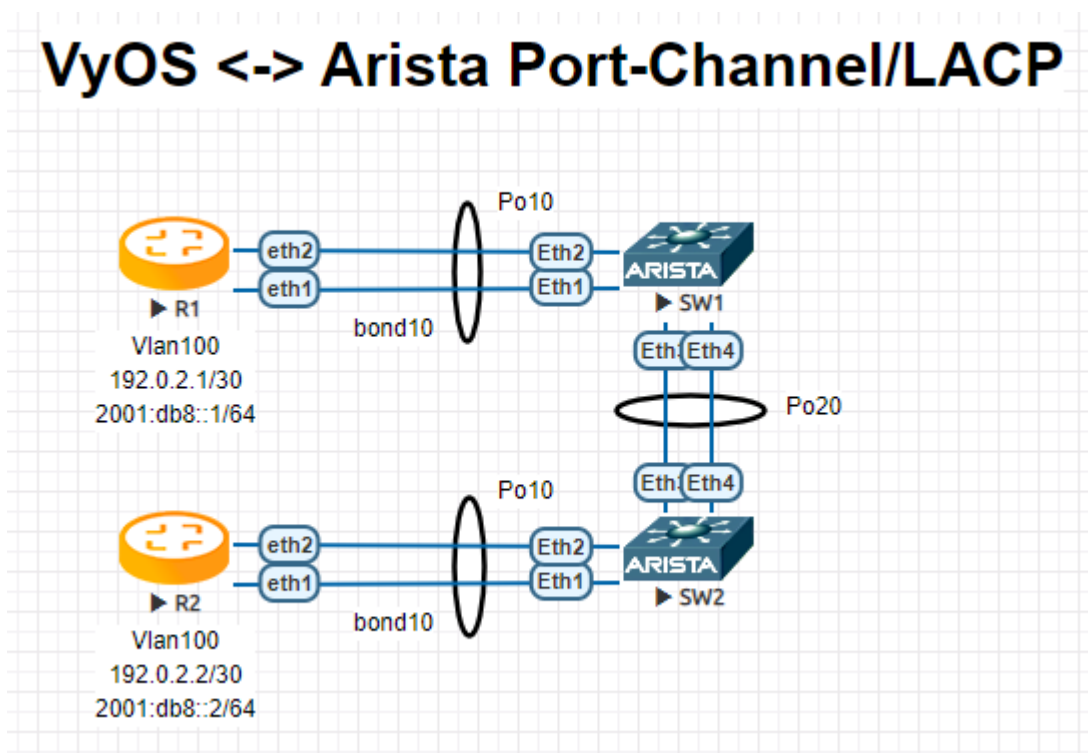

```
# Create trunk with 2 member interfaces (interface 1 and 2) and LACP
trunk 1-2 Trk1 LACP

# Add the required vlans to the trunk
vlan 10 tagged Trk1
vlan 100 tagged Trk1
```

Arista EOS

When utilizing VyOS in an environment with Arista gear you can use this blue print as an initial setup to get an LACP bond / port-channel operational between those two devices.

Lets assume the following topology:

R1

```
interfaces {
    bonding bond10 {
        hash-policy layer3+4
        member {
            interface eth1
            interface eth2
        }
        mode 802.3ad
        vif 100 {
            address 192.0.2.1/30
            address 2001:db8::1/64
        }
    }
}
```

R2

```

interfaces {
    bonding bond10 {
        hash-policy layer3+4
        member {
            interface eth1
            interface eth2
        }
        mode 802.3ad
        vif 100 {
            address 192.0.2.2/30
            address 2001:db8::2/64
        }
    }
}

```

SW1

```

!
vlan 100
    name FOO
!
interface Port-Channel10
    switchport trunk allowed vlan 100
    switchport mode trunk
    spanning-tree portfast
!
interface Port-Channel20
    switchport mode trunk
    no spanning-tree portfast auto
    spanning-tree portfast network
!
interface Ethernet1
    channel-group 10 mode active
!
interface Ethernet2
    channel-group 10 mode active
!
interface Ethernet3
    channel-group 20 mode active
!
interface Ethernet4
    channel-group 20 mode active
!

```

SW2

```

!
vlan 100
    name FOO
!
interface Port-Channel10
    switchport trunk allowed vlan 100
    switchport mode trunk
    spanning-tree portfast
!
interface Port-Channel20
    switchport mode trunk

```

(continues on next page)

(continued from previous page)

```

no spanning-tree portfast auto
spanning-tree portfast network
!
interface Ethernet1
    channel-group 10 mode active
!
interface Ethernet2
    channel-group 10 mode active
!
interface Ethernet3
    channel-group 20 mode active
!
interface Ethernet4
    channel-group 20 mode active
!

```

Note: When using EVE-NG to lab this environment ensure you are using e1000 as the desired driver for your VyOS network interfaces. When using the regular virtio network driver no LACP PDUs will be sent by VyOS thus the port-channel will never become active!

Operation

show interfaces bonding

Show brief interface information.

```

vyos@vyos:~$ show interfaces bonding
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
bond0          -               u/u  my-sw1 int 23 and 24
bond0.10       192.168.0.1/24  u/u  office-net
bond0.100      10.10.10.1/24   u/u  management-net

```

show interfaces bonding <interface>

Show detailed information on given <interface>

```

vyos@vyos:~$ show interfaces bonding bond5
bond5: <NO-CARRIER,BROADCAST,MULTICAST,MASTER,UP> mtu 1500 qdisc noqueue state_
↪DOWN group default qlen 1000
    link/ether 00:50:56:bf:ef:aa brd ff:ff:ff:ff:ff:ff
    inet6 fe80::e862:26ff:fe72:2dac/64 scope link tentative
        valid_lft forever preferred_lft forever

    RX:  bytes  packets  errors  dropped  overrun        mcast
         0         0         0         0         0             0
    TX:  bytes  packets  errors  dropped  carrier  collisions
         0         0         0         0         0             0

```

show interfaces bonding <interface> detail

Show detailed information about the underlying physical links on given bond <interface>.

```
vyos@vyos:~$ show interfaces bonding bond5 detail
Ethernet Channel Bonding Driver: v3.7.1 (April 27, 2011)

Bonding Mode: IEEE 802.3ad Dynamic link aggregation

```

8.4.2 Bridge

A Bridge is a way to connect two Ethernet segments together in a protocol independent way. Packets are forwarded based on Ethernet address, rather than IP address (like a router). Since forwarding is done at Layer 2, all protocols can go transparently through a bridge. The Linux bridge code implements a subset of the ANSI/IEEE 802.1d standard.

Note: Spanning Tree Protocol is not enabled by default in VyOS. *STP Parameter* can be easily enabled if needed.

Configuration

Common interface configuration

set interfaces bridge <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces bridge br0 address 192.0.2.1/24
set interfaces bridge br0 address 2001:db8::1/64
set interfaces bridge br0 address dhcp
set interfaces bridge br0 address dhcpv6
```

set interfaces bridge <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bridge br0 description 'This is an awesome interface running on
↳VyOS'
```

set interfaces bridge <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bridge br0 disable
```

set interfaces bridge <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces bridge br0 disable-flow-control
```

set interfaces bridge <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces bridge br0 disable-link-detect
```

set interfaces bridge <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces bridge br0 mac '00:01:02:03:04:05'
```

set interfaces bridge <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bridge br0 mtu 9000
```

set interfaces bridge <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bridge br0 ip arp-cache-timeout 180
```

set interfaces bridge <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bridge br0 ip disable-arp-filter
```

set interfaces bridge <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bridge br0 ip disable-forwarding
```

set interfaces bridge <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bridge br0 ip enable-arp-accept
```

set interfaces bridge <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bridge br0 ip enable-arp-announce
```

set interfaces bridge <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bridge br0 ip enable-arp-ignore
```

set interfaces bridge <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bridge br0 ip enable-proxy-arp
```

set interfaces bridge <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces bridge <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces bridge <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces bridge br0 ipv6 address autoconf
```

set interfaces bridge <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bridge br0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces bridge <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bridge br0 ipv6 address no-default-link-local
```

set interfaces bridge <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bridge br0 ipv6 disable-forwarding
```

set interfaces bridge <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bridge br0 vrf red
```

DHCP(v6)

set interfaces bridge <interface> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the 'client identifier' option. If the client supplies a 'client identifier', the client MUST use the same 'client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bridge br0 dhcp-options client-id 'foo-bar'
```

set interfaces bridge <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bridge br0 dhcp-options host-name 'VyOS'
```

set interfaces bridge <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bridge br0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces bridge <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bridge br0 dhcp-options no-default-route
```

set interfaces bridge <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bridge br0 dhcp-options default-route-distance 220
```

set interfaces bridge <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bridge br0 dhcp-options reject 192.168.100.0/24
```

set interfaces bridge <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bridge br0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces bridge <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bridge br0 dhcpv6-options parameters-only
```

set interfaces bridge <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bridge br0 dhcpv6-options rapid-commit
```

set interfaces bridge <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bridge br0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces bridge <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bridge br0 dhcpv6-options pd 0 length 56
```

set interfaces bridge <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bridge br0 dhcpv6-options pd 0 interface eth8 address 65534
```

```
set interfaces bridge <interface> dhcpv6-options pd <id> interface <delegatee>
sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bridge br0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Member Interfaces

```
set interfaces bridge <interface> member interface <member>
```

Assign <member> interface to bridge <interface>. A completion helper will help you with all allowed interfaces which can be bridged. This includes *Ethernet*, *Bond / Link Aggregation*, *L2TPv3*, *OpenVPN*, *VXLAN*, *WLAN/WIFI - Wireless LAN*, *Tunnel* and *GENEVE*.

```
set interfaces bridge <interface> member interface <member> priority
<priority>
```

Configure individual bridge port <priority>.

Each bridge has a relative priority and cost. Each interface is associated with a port (number) in the STP code. Each has a priority and a cost, that is used to decide which is the shortest path to forward a packet. The lowest cost path is always used unless the other path is down. If you have multiple bridges and interfaces then you may need to adjust the priorities to achieve optimum performance.

```
set interfaces bridge <interface> member interface <member> cost <cost>
```

Path <cost> value for Spanning Tree Protocol. Each interface in a bridge could have a different speed and this value is used when deciding which link to use. Faster interfaces should have lower costs.

Bridge Options

```
set interfaces bridge <interface> aging <time>
```

MAC address aging <time> in seconds (default: 300).

```
set interfaces bridge <interface> max-age <time>
```

Bridge maximum aging <time> in seconds (default: 20).

If an another bridge in the spanning tree does not send out a hello packet for a long period of time, it is assumed to be dead.

```
set interfaces bridge <interface> igmp querier
```

Enable IGMP querier

STP Parameter

STP (Spanning Tree Protocol) is a network protocol that builds a loop-free logical topology for Ethernet networks. The basic function of STP is to prevent bridge loops and the broadcast radiation that results from them. Spanning tree also allows a network design to include backup links providing fault tolerance if an active link fails.

```
set interfaces bridge <interface> stp
```

Enable spanning tree protocol. STP is disabled by default.

```
set interfaces bridge <interface> forwarding-delay <delay>
```

Spanning Tree Protocol forwarding *<delay>* in seconds (default: 15).

The forwarding delay time is the time spent in each of the listening and learning states before the Forwarding state is entered. This delay is so that when a new bridge comes onto a busy network it looks at some traffic before participating.

```
set interfaces bridge <interface> hello-time <interval>
```

Spanning Tree Protocol hello advertisement *<interval>* in seconds (default: 2).

Periodically, a hello packet is sent out by the Root Bridge and the Designated Bridges. Hello packets are used to communicate information about the topology throughout the entire Bridged Local Area Network.

VLAN

Enable VLAN-Aware Bridge

```
set interfaces bridge <interface> enable-vlan
```

To activate the VLAN aware bridge, you must activate this setting to use VLAN settings for the bridge

VLAN Options

Note: It is not valid to use the *vif 1* option for VLAN aware bridges because VLAN aware bridges assume that all unlabeled packets belong to the default VLAN 1 member and that the VLAN ID of the bridge's parent interface is always 1

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is *vif*.

```
set interfaces bridge <interface> vif <vlan-id>
```

Create a new VLAN interface on interface *<interface>* using the VLAN number provided via *<vlan-id>*.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

Note: Only 802.1Q-tagged packets are accepted on Ethernet vifs.

set interfaces bridge <interface> vif <vlan-id> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces bridge br0 vif 10 address 192.0.2.1/24
set interfaces bridge br0 vif 10 address 2001:db8::1/64
set interfaces bridge br0 vif 10 address dhcp
set interfaces bridge br0 vif 10 address dhcpv6
```

set interfaces bridge <interface> vif <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces bridge br0 vif 10 description 'This is an awesome interface_
↳running on VyOS'
```

set interfaces bridge <interface> vif <vlan-id> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces bridge br0 vif 10 disable
```

set interfaces bridge <interface> vif <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces bridge br0 vif 10 disable-link-detect
```

set interfaces bridge <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces bridge br0 vif 10 mac '00:01:02:03:04:05'
```

set interfaces bridge <interface> vif <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces bridge br0 vif 10 mtu 9000
```

set interfaces bridge <interface> vif <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces bridge br0 vif 10 ip arp-cache-timeout 180
```

set interfaces bridge <interface> vif <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces bridge br0 vif 10 ip disable-arp-filter
```

set interfaces bridge <interface> vif <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces bridge br0 vif 10 ip disable-forwarding
```

set interfaces bridge <interface> vif <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces bridge br0 vif 10 ip enable-arp-accept
```

set interfaces bridge <interface> vif <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces bridge br0 vif 10 ip enable-arp-announce
```

set interfaces bridge <interface> vif <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces bridge br0 vif 10 ip enable-arp-ignore
```

set interfaces bridge <interface> vif <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces bridge br0 vif 10 ip enable-proxy-arp
```

set interfaces bridge <interface> vif <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces bridge <interface> vif <vlan-id> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces bridge <interface> vif <vlan-id> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a

network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces bridge br0 vif 10 ipv6 address autoconf
```

set interfaces bridge <interface> vif <vlan-id> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces bridge br0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces bridge <interface> vif <vlan-id> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces bridge br0 vif 10 ipv6 address no-default-link-local
```

set interfaces bridge <interface> vif <vlan-id> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces bridge br0 vif 10 ipv6 disable-forwarding
```

set interfaces bridge <interface> vif <vlan-id> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces bridge br0 vif 10 vrf red
```

DHCP(v6)

set interfaces bridge <interface> vif <vlan-id> dhcp-options client-id <description>

[RFC 2131](#) states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options client-id 'foo-bar'
```

```
set interfaces bridge <interface> vif <vlan-id> dhcp-options host-name <hostname>
```

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options host-name 'VyOS'
```

```
set interfaces bridge <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>
```

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

```
set interfaces bridge <interface> vif <vlan-id> dhcp-options no-default-route
```

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options no-default-route
```

```
set interfaces bridge <interface> vif <vlan-id> dhcp-options default-route-distance <distance>
```

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces bridge br0 vif 10 dhcp-options default-route-distance 220
```

```
set interfaces bridge <interface> vif <vlan-id> dhcp-options reject <address>
```

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces bridge br0 vif 10 dhcp-options reject 192.168.100.0/24
```

```
set interfaces bridge <interface> vif <vlan-id> dhcpv6-options duid <duid>
```

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces bridge br0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

```
set interfaces bridge <interface> vif <vlan-id> dhcpv6-options parameters-only
```

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces bridge br0 vif 10 dhcpv6-options parameters-only
```

set interfaces bridge <interface> vif <vlan-id> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces bridge br0 vif 10 dhcpv6-options rapid-commit
```

set interfaces bridge <interface> vif <vlan-id> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces bridge br0 vif 10 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 length 56
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id>
interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 interface eth8 address 65534
```

**set interfaces bridge <interface> vif <vlan-id> dhcpv6-options pd <id>
interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces bridge br0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

set interfaces bridge <interface> member interface <member> native-vlan <vlan-id>

Set the native VLAN ID flag of the interface. When a data packet without a VLAN tag enters the port, the data packet will be forced to add a tag of a specific vlan id. When the vlan id flag flows out, the tag of the vlan id will be stripped

Example: Set *eth0* member port to be native VLAN 2

```
set interfaces bridge br1 member interface eth0 native-vlan 2
```

set interfaces bridge <interface> member interface <member> allowed-vlan <vlan-id>

Allows specific VLAN IDs to pass through the bridge member interface. This can either be an individual VLAN id or a range of VLAN ids delimited by a hyphen.

Example: Set *eth0* member port to be allowed VLAN 4

```
set interfaces bridge br1 member interface eth0 allowed-vlan 4
```

Example: Set *eth0* member port to be allowed VLAN 6-8

```
set interfaces bridge br1 member interface eth0 allowed-vlan 6-8
```

Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

set interfaces bridge <interface> mirror ingress <monitor-interface>

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *br1* port to *eth3*

```
set interfaces bridge br1 mirror ingress eth3
```

set interfaces bridge <interface> mirror egress <monitor-interface>

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *br1* port to *eth3*

```
set interfaces bridge br1 mirror egress eth3
```

Examples

Create a basic bridge

Creating a bridge interface is very simple. In this example, we will have:

- A bridge named *br100*
- Member interfaces *eth1* and VLAN 10 on interface *eth2*
- Enable STP

- Bridge answers on IP address 192.0.2.1/24 and 2001:db8::ffff/64

```
set interfaces bridge br100 address 192.0.2.1/24
set interfaces bridge br100 address 2001:db8::ffff/64
set interfaces bridge br100 member interface eth1
set interfaces bridge br100 member interface eth2.10
set interfaces bridge br100 stp
```

This results in the active configuration:

```
vyos@vyos# show interfaces bridge br100
address 192.0.2.1/24
address 2001:db8::ffff/64
member {
    interface eth1 {
    }
    interface eth2.10 {
    }
}
stp
```

Using VLAN aware Bridge

An example of creating a VLAN-aware bridge is as follows:

- A bridge named *br100*
- The member interface *eth1* is a trunk that allows VLAN 10 to pass
- VLAN 10 on member interface *eth2* (ACCESS mode)
- Enable STP
- Bridge answers on IP address 192.0.2.1/24 and 2001:db8::ffff/64

```
set interfaces bridge br100 enable-vlan
set interfaces bridge br100 member interface eth1 allowed-vlan 10
set interfaces bridge br100 member interface eth2 native-vlan 10
set interfaces bridge br100 vif 10 address 192.0.2.1/24
set interfaces bridge br100 vif 10 address 2001:db8::ffff/64
set interfaces bridge br100 stp
```

This results in the active configuration:

```
vyos@vyos# show interfaces bridge br100
enable-vlan
member {
    interface eth1 {
        allowed-vlan 10
    }
    interface eth2 {
        native-vlan 10
    }
}
stp
vif 10 {
    address 192.0.2.1/24
```

(continues on next page)

(continued from previous page)

```

    address 2001:db8::ffff/64
}

```

Using the operation mode command to view Bridge Information

show bridge

The *show bridge* operational command can be used to display configured bridges:

```

vyos@vyos:~$ show bridge
3: eth1: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master br0 state forwarding
priority 32 cost 100
4: eth2: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 master br0 state forwarding
priority 32 cost 100

```

show bridge <name> fdb

Show bridge <name> fdb displays the current forwarding table:

```

vyos@vyos:~$ show bridge br0 fdb
50:00:00:08:00:01 dev eth1 vlan 20 master br0 permanent
50:00:00:08:00:01 dev eth1 vlan 10 master br0 permanent
50:00:00:08:00:01 dev eth1 master br0 permanent
33:33:00:00:00:01 dev eth1 self permanent
33:33:00:00:00:02 dev eth1 self permanent
01:00:5e:00:00:01 dev eth1 self permanent
50:00:00:08:00:02 dev eth2 vlan 20 master br0 permanent
50:00:00:08:00:02 dev eth2 vlan 10 master br0 permanent
50:00:00:08:00:02 dev eth2 master br0 permanent
33:33:00:00:00:01 dev eth2 self permanent
33:33:00:00:00:02 dev eth2 self permanent
01:00:5e:00:00:01 dev eth2 self permanent
33:33:00:00:00:01 dev br0 self permanent
33:33:00:00:00:02 dev br0 self permanent
33:33:ff:08:00:01 dev br0 self permanent
01:00:5e:00:00:6a dev br0 self permanent
33:33:00:00:00:6a dev br0 self permanent
01:00:5e:00:00:01 dev br0 self permanent
33:33:ff:00:00:00 dev br0 self permanent

```

show bridge <name> mdb

Show bridge <name> mdb displays the current multicast group membership table. The table is populated by IGMP and MLD snooping in the bridge driver automatically.

```

vyos@vyos:~$ show bridge br0 mdb
dev br0 port br0 grp ff02::1:ff00:0 temp vid 1
dev br0 port br0 grp ff02::2 temp vid 1
dev br0 port br0 grp ff02::1:ff08:1 temp vid 1
dev br0 port br0 grp ff02::6a temp vid 1

```

8.4.3 Dummy

The dummy interface is really a little exotic, but rather useful nevertheless. Dummy interfaces are much like the *Loopback* interface, except you can have as many as you want.

Note: Dummy interfaces can be used as interfaces that always stay up (in the same fashion to loopbacks in Cisco IOS), or for testing purposes.

Hint: On systems with multiple redundant uplinks and routes, it's a good idea to use a dedicated address for management and dynamic routing protocols. However, assigning that address to a physical link is risky: if that link goes down, that address will become inaccessible. A common solution is to assign the management address to a loopback or a dummy interface and advertise that address via all physical links, so that it's reachable through any of them. Since in Linux-based systems, there can be only one loopback interface, it's better to use a dummy interface for that purpose, since they can be added, removed, and taken up and down independently.

Configuration

Common interface configuration

set interfaces dummy <interface> address <address>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces dummy dum0 address 192.0.2.1/24
set interfaces dummy dum0 address 2001:db8::1/64
```

set interfaces dummy <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces dummy dum0 description 'This is an awesome interface running on ↵
↳ VyOS'
```

set interfaces dummy <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces dummy dum0 disable
```

set interfaces dummy <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces dummy dum0 vrf red
```

Operation

show interfaces dummy

Show brief interface information.

```
vyos@vyos:~$ show interfaces dummy
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
dum0           172.18.254.201/32  u/u
```

show interfaces dummy <interface>

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces ethernet eth0
dum0: <BROADCAST,NOARP,UP,LOWER_UP> mtu 1500 qdisc noqueue state UNKNOWN group_
→default qlen 1000
  link/ether 26:7c:8e:bc:fc:f5 brd ff:ff:ff:ff:ff:ff
  inet 172.18.254.201/32 scope global dum0
    valid_lft forever preferred_lft forever
  inet6 fe80::247c:8eff:febc:fcf5/64 scope link
    valid_lft forever preferred_lft forever

RX:  bytes    packets    errors    dropped    overrun    mcast
     0         0         0         0         0         0
TX:  bytes    packets    errors    dropped    carrier    collisions
1369707    4267         0         0         0         0
```

8.4.4 Ethernet

This will be the most widely used interface on a router carrying traffic to the real world.

Configuration

Common interface configuration

set interfaces ethernet <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces ethernet eth0 address 192.0.2.1/24
set interfaces ethernet eth0 address 2001:db8::1/64
set interfaces ethernet eth0 address dhcp
set interfaces ethernet eth0 address dhcpv6
```

set interfaces ethernet <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 description 'This is an awesome interface running
→on VyOS'
```

set interfaces ethernet <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 disable
```

set interfaces ethernet <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces ethernet eth0 disable-flow-control
```

set interfaces ethernet <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces ethernet eth0 disable-link-detect
```

set interfaces ethernet <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 mac '00:01:02:03:04:05'
```

set interfaces ethernet <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 mtu 9000
```

set interfaces ethernet <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 ip arp-cache-timeout 180
```

set interfaces ethernet <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 ip disable-arp-filter
```

set interfaces ethernet <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 ip disable-forwarding
```

set interfaces ethernet <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 ip enable-arp-accept
```

set interfaces ethernet <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 ip enable-arp-announce
```

set interfaces ethernet <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 ip enable-arp-ignore
```

set interfaces ethernet <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 ip enable-proxy-arp
```

set interfaces ethernet <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces ethernet <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces ethernet <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPV6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers

respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces ethernet eth0 ipv6 address autoconf
```

set interfaces ethernet <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces ethernet <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 ipv6 address no-default-link-local
```

set interfaces ethernet <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 ipv6 disable-forwarding
```

set interfaces ethernet <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vrf red
```

DHCP(v6)

set interfaces ethernet <interface> dhcp-options client-id <description>

[RFC 2131](#) states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 dhcp-options client-id 'foo-bar'
```

set interfaces ethernet <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 dhcp-options host-name 'VyOS'
```

set interfaces ethernet <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces ethernet <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 dhcp-options no-default-route
```

set interfaces ethernet <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 dhcp-options default-route-distance 220
```

set interfaces ethernet <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 dhcp-options reject 192.168.100.0/24
```

set interfaces ethernet <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces ethernet <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 dhcpv6-options parameters-only
```

set interfaces ethernet <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 dhcpv6-options rapid-commit
```

set interfaces ethernet <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces ethernet <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 dhcpv6-options pd 0 length 56
```

set interfaces ethernet <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces ethernet <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Ethernet options

set interfaces ethernet <interface> duplex <auto | full | half>

Configure physical interface duplex setting.

- auto - interface duplex setting is auto-negotiated
- full - always use full-duplex
- half - always use half-duplex

VyOS default will be *auto*.

```
set interfaces ethernet <interface> speed <auto | 10 | 100 | 1000 | 2500 | 5000 | 10000 | 25000 | 40000 | 50000 | 100000>
```

Configure physical interface speed setting.

- auto - interface speed is auto-negotiated
- 10 - 10 MBit/s
- 100 - 100 MBit/s
- 1000 - 1 GBit/s
- 2500 - 2.5 GBit/s
- 5000 - 5 GBit/s
- 10000 - 10 GBit/s
- 25000 - 25 GBit/s
- 40000 - 40 GBit/s
- 50000 - 50 GBit/s
- 100000 - 100 GBit/s

VyOS default will be *auto*.

```
set interfaces ethernet <interface> mirror <interface>
```

Use this command to mirror the inbound traffic from one Ethernet interface to another interface. This feature is typically used to provide a copy of traffic inbound on one interface to a system running a monitoring or IPS application on another interface. The benefit of mirroring the traffic is that the application is isolated from the source traffic and so application processing does not affect the traffic or the system performance.

Example:

```
set interfaces ethernet eth0 mirror eth1
```

Offloading

```
set interfaces ethernet <interface> offload <gro | gso | sg | tso | ufo | rps>
```

Enable different types of hardware offloading on the given NIC.

GSO (Generic Segmentation Offload) is a pure software offload that is meant to deal with cases where device drivers cannot perform the offloads described above. What occurs in GSO is that a given skbuff will have its data broken out over multiple skbuffs that have been resized to match the MSS provided via `skb_shinfo()->gso_size`.

Before enabling any hardware segmentation offload a corresponding software offload is required in GSO. Otherwise it becomes possible for a frame to be re-routed between devices and end up being unable to be transmitted.

GRO (Generic receive offload) is the complement to GSO. Ideally any frame assembled by GRO should be segmented to create an identical sequence of frames using GSO, and any sequence of frames segmented by GSO should be able to be reassembled back to the original by GRO. The only exception to this is IPv4 ID in

the case that the DF bit is set for a given IP header. If the value of the IPv4 ID is not sequentially incrementing it will be altered so that it is when a frame assembled via GRO is segmented via GSO.

RPS (Receive Packet Steering) is logically a software implementation of RSS (Receive Side Scaling). Being in software, it is necessarily called later in the datapath. Whereas RSS selects the queue and hence CPU that will run the hardware interrupt handler, RPS selects the CPU to perform protocol processing above the interrupt handler. This is accomplished by placing the packet on the desired CPU's backlog queue and waking up the CPU for processing. RPS has some advantages over RSS:

- it can be used with any NIC,
- software filters can easily be added to hash over new protocols,
- it does not increase hardware device interrupt rate (although it does introduce inter-processor interrupts (IPIs)).

set interfaces ethernet <interface> xdp

Enable support for Linux XDP on recent 1.4 rolling releases. You must enable it for every interface which should participate in the XDP forwarding.

XDP is an eBPF based high performance data path merged in the Linux kernel since version 4.8. The idea behind XDP is to add an early hook in the RX path of the kernel, and let a user supplied eBPF program decide the fate of the packet. The hook is placed in the NIC driver just after the interrupt processing, and before any memory allocation needed by the network stack itself, because memory allocation can be an expensive operation.

Warning: This is highly experimental!

Note: Enabling this feature will break any form of NAT or Firewalling on this interface, as XDP is handled way earlier in the driver then iptables/ nftables.

Enabling this feature will only load the XDP router code as described here:

<https://blog.apnic.net/2020/04/30/how-to-build-an-xdp-based-bgp-peering-router/>

Example:

```
set interfaces ethernet eth0 xdp
```

Authentication (EAPoL)

EAP (Extensible Authentication Protocol) over LAN (EAPoL) is a network port authentication protocol used in IEEE 802.1X (Port Based Network Access Control) developed to give a generic network sign-on to access network resources.

EAPoL comes with an identify option. We automatically use the interface MAC address as identity parameter.

set interfaces ethernet <interface> eapol ca-cert-file <file>

SSL CA (Certificate Authority) x509 PEM file used afor authentication of the remote side.

```
set interfaces ethernet eth0 eapol ca-cert-file /config/auth/ca.pem
```

set interfaces ethernet <interface> eapol cert-file <file>

SSL/x509 public certificate file provided by the client to authenticate against the 802.1x system.

```
set interfaces ethernet eth0 eapol cert-file /config/auth/public.pem
```

set interfaces ethernet <interface> eapol key-file <file>

SSL/x509 private certificate file provided by the client to authenticate against the 802.1x system.

```
set interfaces ethernet eth0 eapol key-file /config/auth/private.key
```

VLAN

Regular VLANs (802.1q)

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

set interfaces ethernet <interface> vif <vlan-id>

Create a new VLAN interface on interface `<interface>` using the VLAN number provided via `<vlan-id>`.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

Note: Only 802.1Q-tagged packets are accepted on Ethernet vifs.

set interfaces ethernet <interface> vif <vlan-id> address <address | dhcp | dhcpv6>

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces ethernet eth0 vif 10 address 192.0.2.1/24
set interfaces ethernet eth0 vif 10 address 2001:db8::1/64
set interfaces ethernet eth0 vif 10 address dhcp
set interfaces ethernet eth0 vif 10 address dhcpv6
```

set interfaces ethernet <interface> vif <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 vif 10 description 'This is an awesome interface_
→running on VyOS'
```

set interfaces ethernet <interface> vif <vlan-id> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 vif 10 disable
```

set interfaces ethernet <interface> vif <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces ethernet eth0 vif 10 disable-link-detect
```

set interfaces ethernet <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 vif 10 mac '00:01:02:03:04:05'
```

set interfaces ethernet <interface> vif <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 vif 10 mtu 9000
```

set interfaces ethernet <interface> vif <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 vif 10 ip arp-cache-timeout 180
```

set interfaces ethernet <interface> vif <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 vif 10 ip disable-arp-filter
```

set interfaces ethernet <interface> vif <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 vif 10 ip disable-forwarding
```

set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-accept
```

set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-announce
```

set interfaces ethernet <interface> vif <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 vif 10 ip enable-arp-ignore
```

set interfaces ethernet <interface> vif <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 vif 10 ip enable-proxy-arp
```

set interfaces ethernet <interface> vif <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces ethernet <interface> vif <vlan-id> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces ethernet <interface> vif <vlan-id> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address autoconf
```

set interfaces ethernet <interface> vif <vlan-id> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces ethernet <interface> vif <vlan-id> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 address no-default-link-local
```

set interfaces ethernet <interface> vif <vlan-id> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 vif 10 ipv6 disable-forwarding
```

set interfaces ethernet <interface> vif <vlan-id> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vif 10 vrf red
```

DHCP(v6)

set interfaces ethernet <interface> vif <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options client-id 'foo-bar'
```

set interfaces ethernet <interface> vif <vlan-id> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options host-name 'VyOS'
```

set interfaces ethernet <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

set interfaces ethernet <interface> vif <vlan-id> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options no-default-route
```

set interfaces ethernet <interface> vif <vlan-id> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options default-route-distance 220
```

set interfaces ethernet <interface> vif <vlan-id> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 vif 10 dhcp-options reject 192.168.100.0/24
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options parameters-only
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options rapid-commit
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 length 56
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 interface eth8 address_
→65534
```

set interfaces ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

QinQ (802.1ad)

IEEE [802.1ad](#) was an Ethernet networking standard informally known as QinQ as an amendment to IEEE standard 802.1q VLAN interfaces as described above. 802.1ad was incorporated into the base [802.1q](#) standard in 2011. The technique is also known as provider bridging, Stacked VLANs, or simply QinQ or Q-in-Q. “Q-in-Q” can for supported devices apply to C-tag stacking on C-tag (Ethernet Type = 0x8100).

The original [802.1q](#) specification allows a single Virtual Local Area Network (VLAN) header to be inserted into an Ethernet frame. QinQ allows multiple VLAN tags to be inserted into a single frame, an essential capability for

implementing Metro Ethernet network topologies. Just as QinQ extends 802.1Q, QinQ itself is extended by other Metro Ethernet protocols.

In a multiple VLAN header context, out of convenience the term “VLAN tag” or just “tag” for short is often used in place of “802.1q VLAN header”. QinQ allows multiple VLAN tags in an Ethernet frame; together these tags constitute a tag stack. When used in the context of an Ethernet frame, a QinQ frame is a frame that has 2 VLAN 802.1q headers (double-tagged).

In VyOS the terms `vif-s` and `vif-c` stand for the ethertype tags that are used.

The inner tag is the tag which is closest to the payload portion of the frame. It is officially called C-TAG (customer tag, with ethertype 0x8100). The outer tag is the one closer/closest to the Ethernet header, its name is S-TAG (service tag with Ethernet Type = 0x88a8).

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address 192.0.2.1/24
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address 2001:db8::1/64
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address dhcp
set interfaces ethernet eth0 vif-s 1000 vif-c 20 address dhcpv6
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 description 'This is an awesome
↳ interface running on VyOS'
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 disable
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 disable-link-detect
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 mac '00:01:02:03:04:05'
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 mtu 9000
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip arp-cache-timeout 180
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip disable-arp-filter
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip disable-forwarding
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-accept
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-announce
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-arp-ignore
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ip enable-proxy-arp
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address autoconf
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address eui64_
↪2001:db8:beef::/64
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 address no-default-link-
↳ local
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 ipv6 disable-forwarding
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 vrf red
```

DHCP(v6)

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the 'client identifier' option. If the client supplies a 'client identifier', the client MUST use the same 'client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options client-id 'foo-bar'
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options host-name 'VyOS'
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options vendor-class-id
↳ 'VyOS'
```

set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options no-default-route
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options default-route-  
→distance 220
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcp-options reject 192.168.100.  
→0/24
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 duid  
→'0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options parameters-only
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options rapid-commit
```

**set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options temporary**

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 length 56
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
↳eth8 address 65534
```

```
set interfaces ethernet <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces ethernet eth0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
↳eth8 sla-id 1
```

Port Mirror (SPAN)

SPAN port mirroring can copy the inbound/outbound traffic of the interface to the specified interface, usually the interface can be connected to some special equipment, such as behavior control system, intrusion detection system and traffic collector, and can copy all related traffic from this port

VyOS uses the *mirror* option to configure port mirroring. The configuration is divided into 2 different directions. Destination ports should be configured for different traffic directions.

```
set interfaces ethernet <interface> mirror ingress <monitor-interface>
```

Configure port mirroring for *interface* inbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the inbound traffic of *eth1* port to *eth3*

```
set interfaces ethernet eth1 mirror ingress eth3
```

set interfaces ethernet <interface> mirror egress <monitor-interface>

Configure port mirroring for *interface* outbound traffic and copy the traffic to *monitor-interface*

Example: Mirror the outbound traffic of *eth1* port to *eth3*

```
set interfaces ethernet eth1 mirror egress eth3
```

Operation

show interfaces ethernet

Show brief interface information.

```
vyos@vyos:~$ show interfaces ethernet
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L Description
-----
eth0           172.18.201.10/24 u/u LAN
eth1           172.18.202.11/24 u/u WAN
eth2           -                u/D
```

show interfaces ethernet <interface>

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces ethernet eth0
eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP group_

8.4.5 GENEVE

GENEVE (Generic Network Virtualization Encapsulation) supports all of the capabilities of VXLAN (Virtual Extensible LAN), NVGRE (Network Virtualization using Generic Routing Encapsulation), and STT (Stateless Transport Tunneling) and was designed to overcome their perceived limitations. Many believe GENEVE could eventually replace these earlier formats entirely.

GENEVE is designed to support network virtualization use cases, where tunnels are typically established to act as a backplane between the virtual switches residing in hypervisors, physical switches, or middleboxes or other appliances. An arbitrary IP network can be used as an underlay although Clos networks - A technique for composing network fabrics larger than a single switch while maintaining non-blocking bandwidth across connection points. ECMP is used to divide traffic across the multiple links and switches that constitute the fabric. Sometimes termed “leaf and spine” or “fat tree” topologies.

Geneve Header:

```

```

Configuration

Common interface configuration

set interfaces geneve <interface> address <address>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces geneve gnv0 address 192.0.2.1/24
set interfaces geneve gnv0 address 2001:db8::1/64
```

set interfaces geneve <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces geneve gnv0 description 'This is an awesome interface running on
→VyOS'
```

set interfaces geneve <interface> disable

Disable given *<interface>*. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces geneve gnv0 disable
```

set interfaces geneve <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces geneve gnv0 disable-flow-control
```

set interfaces geneve <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces geneve gnv0 disable-link-detect
```

set interfaces geneve <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given *<interface>*.

Example:

```
set interfaces geneve gnv0 mac '00:01:02:03:04:05'
```

set interfaces geneve <interface> mtu <mtu>

Configure MTU on given *<interface>*. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces geneve gnv0 mtu 9000
```

set interfaces geneve <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces geneve gnv0 ip arp-cache-timeout 180
```

set interfaces geneve <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces geneve gnv0 ip disable-arp-filter
```

set interfaces geneve <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces geneve gnv0 ip disable-forwarding
```

set interfaces geneve <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces geneve gnv0 ip enable-arp-accept
```

set interfaces geneve <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces geneve gnv0 ip enable-arp-announce
```

set interfaces geneve <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces geneve gnv0 ip enable-arp-ignore
```

set interfaces geneve <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces geneve gnv0 ip enable-proxy-arp
```

set interfaces geneve <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces geneve <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces geneve <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces geneve gnv0 ipv6 address autoconf
```

set interfaces geneve <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces geneve gnv0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces geneve <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces geneve gnv0 ipv6 address no-default-link-local
```

set interfaces geneve <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces geneve gnv0 ipv6 disable-forwarding
```

set interfaces geneve <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces geneve gnv0 vrf red
```

GENEVE options

set interfaces geneve gnv0 remote <address>

Configure GENEVE tunnel far end/remote tunnel endpoint.

set interfaces geneve gnv0 vni <vni>

VNI (Virtual Network Identifier) is an identifier for a unique element of a virtual network. In many situations this may represent an L2 segment, however, the control plane defines the forwarding semantics of decapsulated packets. The VNI MAY be used as part of ECMP forwarding decisions or MAY be used as a mechanism to distinguish between overlapping address spaces contained in the encapsulated packet when load balancing across CPUs.

8.4.6 L2TPv3

Layer 2 Tunnelling Protocol Version 3 is an IETF standard related to L2TP that can be used as an alternative protocol to [MPLS](#) for encapsulation of multiprotocol Layer 2 communications traffic over IP networks. Like L2TP, L2TPv3 provides a pseudo-wire service but is scaled to fit carrier requirements.

L2TPv3 can be regarded as being to MPLS what IP is to ATM: a simplified version of the same concept, with much of the same benefit achieved at a fraction of the effort, at the cost of losing some technical features considered less important in the market.

In the case of L2TPv3, the features lost are teletraffic engineering features considered important in MPLS. However, there is no reason these features could not be re-engineered in or on top of L2TPv3 in later products.

The protocol overhead of L2TPv3 is also significantly bigger than MPLS.

L2TPv3 is described in [RFC 3921](#).

Configuration

Common interface configuration

set interfaces l2tpv3 <interface> address <address>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces l2tpv3 l2tpeth0 address 192.0.2.1/24
set interfaces l2tpv3 l2tpeth0 address 2001:db8::1/64
```

set interfaces l2tpv3 <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces l2tpv3 l2tpeth0 description 'This is an awesome interface running_
↳on VyOS'
```

set interfaces l2tpv3 <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces l2tpv3 l2tpeth0 disable
```

set interfaces l2tpv3 <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces l2tpv3 l2tpeth0 disable-flow-control
```

set interfaces l2tpv3 <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces l2tpv3 l2tpeth0 disable-link-detect
```

set interfaces l2tpv3 <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces l2tpv3 l2tpeth0 mac '00:01:02:03:04:05'
```

set interfaces l2tpv3 <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces l2tpv3 l2tpeth0 mtu 9000
```

set interfaces l2tpv3 <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip arp-cache-timeout 180
```

set interfaces l2tpv3 <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip disable-arp-filter
```

set interfaces l2tpv3 <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces l2tpv3 l2tpeth0 ip disable-forwarding
```

set interfaces l2tpv3 <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-accept
```

set interfaces l2tpv3 <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-announce
```

set interfaces l2tpv3 <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces l2tpv3 l2tpeth0 ip enable-arp-ignore
```

set interfaces l2tpv3 <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces l2tpv3 l2tpeth0 ip enable-proxy-arp
```

set interfaces l2tpv3 <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation

- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces l2tpv3 <interface> ip source-validation <strict | loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces l2tpv3 <interface> ipv6 address autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address autoconf
```

```
set interfaces l2tpv3 <interface> ipv6 address eui64 <prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address eui64 2001:db8:beef::/64
```

```
set interfaces l2tpv3 <interface> ipv6 address no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 address no-default-link-local
```

```
set interfaces l2tpv3 <interface> ipv6 disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces l2tpv3 l2tpeth0 ipv6 disable-forwarding
```

```
set interfaces l2tpv3 <interface> vrf <vrf>
```

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces l2tpv3 l2tpeth0 vrf red
```

L2TPv3 options

set interfaces l2tpv3 <interface> encapsulation <udp | ip>

Set the encapsulation type of the tunnel. Valid values for encapsulation are: udp, ip.

This defaults to UDP

set interfaces l2tpv3 <interface> source-address <address>

Set the IP address of the local interface to be used for the tunnel.

This address must be the address of a local interface. It may be specified as an IPv4 address or an IPv6 address.

set interfaces l2tpv3 <interface> remote <address>

Set the IP address of the remote peer. It may be specified as an IPv4 address or an IPv6 address.

set interfaces l2tpv3 <interface> session-id <id>

Set the session id, which is a 32-bit integer value. Uniquely identifies the session being created. The value used must match the peer_session_id value being used at the peer.

set interfaces l2tpv3 <interface> peer-session-id <id>

Set the peer-session-id, which is a 32-bit integer value assigned to the session by the peer. The value used must match the session_id value being used at the peer.

set interfaces l2tpv3 <interface> tunnel-id <id>

Set the tunnel id, which is a 32-bit integer value. Uniquely identifies the tunnel into which the session will be created.

set interfaces l2tpv3 <interface> peer-tunnel-id <id>

Set the tunnel id, which is a 32-bit integer value. Uniquely identifies the tunnel into which the session will be created.

Example

Over IP

```
# show interfaces l2tpv3
l2tpv3 l2tpeth10 {
    address 192.168.37.1/27
    encapsulation ip
    source-address 192.0.2.1
    peer-session-id 100
    peer-tunnel-id 200
    remote 203.0.113.24
```

(continues on next page)

(continued from previous page)

```

    session-id 100
    tunnel-id 200
}

```

The inverse configuration has to be applied to the remote side.

Over UDP

UDP mode works better with NAT:

- Set source-address to your local IP (LAN).
- Add a forwarding rule matching UDP port on your internet router.

```

# show interfaces l2tpv3
l2tpv3 l2tpeth10 {
    address 192.168.37.1/27
    destination-port 9001
    encapsulation udp
    source-address 192.0.2.1
    peer-session-id 100
    peer-tunnel-id 200
    remote 203.0.113.24
    session-id 100
    source-port 9000
    tunnel-id 200
}

```

To create more than one tunnel, use distinct UDP ports.

Over IPSec, L2 VPN (bridge)

This is the LAN extension use case. The eth0 port of the distant VPN peers will be directly connected like if there was a switch between them.

IPSec:

```

set vpn ipsec ipsec-interfaces <VPN-interface>
set vpn ipsec esp-group test-ESP-1 compression 'disable'
set vpn ipsec esp-group test-ESP-1 lifetime '3600'
set vpn ipsec esp-group test-ESP-1 mode 'transport'
set vpn ipsec esp-group test-ESP-1 pfs 'enable'
set vpn ipsec esp-group test-ESP-1 proposal 1 encryption 'aes128'
set vpn ipsec esp-group test-ESP-1 proposal 1 hash 'sha1'
set vpn ipsec ike-group test-IKE-1 ikev2-reauth 'no'
set vpn ipsec ike-group test-IKE-1 key-exchange 'ikev1'
set vpn ipsec ike-group test-IKE-1 lifetime '3600'
set vpn ipsec ike-group test-IKE-1 proposal 1 dh-group '5'
set vpn ipsec ike-group test-IKE-1 proposal 1 encryption 'aes128'
set vpn ipsec ike-group test-IKE-1 proposal 1 hash 'sha1'
set vpn ipsec site-to-site peer <peer-ip> authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer <peer-ip> authentication pre-shared-secret <pre-
↪shared-key>
set vpn ipsec site-to-site peer <peer-ip> connection-type 'initiate'
set vpn ipsec site-to-site peer <peer-ip> ike-group 'test-IKE-1'

```

(continues on next page)

(continued from previous page)

```
set vpn ipsec site-to-site peer <peer-ip> ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer <peer-ip> local-address <local-ip>
set vpn ipsec site-to-site peer <peer-ip> tunnel 1 allow-nat-networks 'disable'
set vpn ipsec site-to-site peer <peer-ip> tunnel 1 allow-public-networks 'disable'
set vpn ipsec site-to-site peer <peer-ip> tunnel 1 esp-group 'test-ESP-1'
set vpn ipsec site-to-site peer <peer-ip> tunnel 1 protocol 'l2tp'
```

Bridge:

```
set interfaces bridge br0 description 'L2 VPN Bridge'
# remote side in this example:
# set interfaces bridge br0 address '172.16.30.18/30'
set interfaces bridge br0 address '172.16.30.17/30'
set interfaces bridge br0 member interface eth0
set interfaces ethernet eth0 description 'L2 VPN Physical port'
```

L2TPv3:

```
set interfaces bridge br0 member interface 'l2tpeth0'
set interfaces l2tpv3 l2tpeth0 description 'L2 VPN Tunnel'
set interfaces l2tpv3 l2tpeth0 destination-port '5000'
set interfaces l2tpv3 l2tpeth0 encapsulation 'ip'
set interfaces l2tpv3 l2tpeth0 source-address <local-ip>
set interfaces l2tpv3 l2tpeth0 mtu '1500'
set interfaces l2tpv3 l2tpeth0 peer-session-id '110'
set interfaces l2tpv3 l2tpeth0 peer-tunnel-id '10'
set interfaces l2tpv3 l2tpeth0 remote <peer-ip>
set interfaces l2tpv3 l2tpeth0 session-id '110'
set interfaces l2tpv3 l2tpeth0 source-port '5000'
set interfaces l2tpv3 l2tpeth0 tunnel-id '10'
```

8.4.7 Loopback

The loopback networking interface is a virtual network device implemented entirely in software. All traffic sent to it “loops back” and just targets services on your local machine.

Note: There can only be one loopback `lo` interface on the system. If you need multiple interfaces, please use the *Dummy* interface type.

Hint: A lookback interface is always up, thus it could be used for management traffic or as source/destination for and IGP (Interior Gateway Protocol) like *BGP* so your internal BGP link is not dependent on physical link states and multiple routes can be chosen to the destination. A *Dummy* Interface should always be preferred over a *Loopback* interface.

Configuration

Common interface configuration

```
set interfaces loopback <interface> address <address>
```

Configure interface *<interface>* with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces loopback lo address 192.0.2.1/24
set interfaces loopback lo address 2001:db8::1/64
```

set interfaces loopback <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces loopback lo description 'This is an awesome interface running on
↳VyOS'
```

Operation

show interfaces loopback

Show brief interface information.

```
vyos@vyos:~$ show interfaces loopback
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
lo              127.0.0.1/8     u/u
               ::1/128
```

show interfaces loopback lo

Show detailed information on the given loopback interface *lo*.

```
vyos@vyos:~$ show interfaces ethernet eth0
lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN group default
↳qlen 1000
  link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
  inet 127.0.0.1/8 scope host lo
    valid_lft forever preferred_lft forever
  inet6 ::1/128 scope host
    valid_lft forever preferred_lft forever

RX:  bytes    packets    errors    dropped    overrun    mcast
    300         6         0         0         0         0
TX:  bytes    packets    errors    dropped    carrier    collisions
    300         6         0         0         0         0
```

8.4.8 MACsec

MACsec is an IEEE standard (IEEE 802.1AE) for MAC security, introduced in 2006. It defines a way to establish a protocol independent connection between two hosts with data confidentiality, authenticity and/or integrity, using GCM-AES-128. MACsec operates on the Ethernet layer and as such is a layer 2 protocol, which means it's designed

to secure traffic within a layer 2 network, including DHCP or ARP requests. It does not compete with other security solutions such as IPsec (layer 3) or TLS (layer 4), as all those solutions are used for their own specific use cases.

Configuration

Common interface configuration

set interfaces macsec <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces macsec macsec0 address 192.0.2.1/24
set interfaces macsec macsec0 address 2001:db8::1/64
set interfaces macsec macsec0 address dhcp
set interfaces macsec macsec0 address dhcpv6
```

set interfaces macsec <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces macsec macsec0 description 'This is an awesome interface running
→on VyOS'
```

set interfaces macsec <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces macsec macsec0 disable
```

set interfaces macsec <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces macsec macsec0 disable-flow-control
```

set interfaces macsec <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces macsec macsec0 disable-link-detect
```

set interfaces macsec <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces macsec macsec0 mac '00:01:02:03:04:05'
```

set interfaces macsec <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces macsec macsec0 mtu 9000
```

set interfaces macsec <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces macsec macsec0 ip arp-cache-timeout 180
```

set interfaces macsec <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces macsec macsec0 ip disable-arp-filter
```

set interfaces macsec <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces macsec macsec0 ip disable-forwarding
```

set interfaces macsec <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces macsec macsec0 ip enable-arp-accept
```

set interfaces macsec <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces macsec macsec0 ip enable-arp-announce
```

set interfaces macsec <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces macsec macsec0 ip enable-arp-ignore
```

set interfaces macsec <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces macsec macsec0 ip enable-proxy-arp
```

set interfaces macsec <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation

- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces macsec <interface> ip source-validation <strict | loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces macsec <interface> ipv6 address autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces macsec macsec0 ipv6 address autoconf
```

```
set interfaces macsec <interface> ipv6 address eui64 <prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces macsec macsec0 ipv6 address eui64 2001:db8:beef::/64
```

```
set interfaces macsec <interface> ipv6 address no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces macsec macsec0 ipv6 address no-default-link-local
```

```
set interfaces macsec <interface> ipv6 disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces macsec macsec0 ipv6 disable-forwarding
```

```
set interfaces macsec <interface> vrf <vrf>
```

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces macsec macsec0 vrf red
```

DHCP(v6)

set interfaces macsec <interface> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces macsec macsec0 dhcp-options client-id 'foo-bar'
```

set interfaces macsec <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces macsec macsec0 dhcp-options host-name 'VyOS'
```

set interfaces macsec <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces macsec macsec0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces macsec <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces macsec macsec0 dhcp-options no-default-route
```

set interfaces macsec <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces macsec macsec0 dhcp-options default-route-distance 220
```

set interfaces macsec <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces macsec macsec0 dhcp-options reject 192.168.100.0/24
```

set interfaces macsec <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces macsec macsec0 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces macsec <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces macsec macsec0 dhcpv6-options parameters-only
```

set interfaces macsec <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces macsec macsec0 dhcpv6-options rapid-commit
```

set interfaces macsec <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces macsec macsec0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces macsec <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces macsec macsec0 dhcpv6-options pd 0 length 56
```

set interfaces macsec <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces macsec macsec0 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces macsec <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces macsec macsec0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

MACsec options

set interfaces macsec <interface> security cipher <gcm-aes-128|gcm-aes-256>

Select cipher suite used for cryptographic operations. This setting is mandatory.

set interfaces macsec <interface> security encrypt

MACsec only provides authentication by default, encryption is optional. This command will enable encryption for all outgoing packets.

set interfaces macsec <interface> source-interface <physical-source>

A physical interface is required to connect this MACsec instance to. Traffic leaving this interface will now be authenticated/encrypted.

Key Management

MKA (MACsec Key Agreement protocol) is used to synchronize keys between individual peers.

set interfaces macsec <interface> security mka cak <key>

IEEE 802.1X/MACsec pre-shared key mode. This allows configuring MACsec with a pre-shared key using a (CAK,CKN) pair.

set interfaces macsec <interface> security mka ckn <key>

CAK Name

set interfaces macsec <interface> security mka priority <priority>

The peer with lower priority will become the key server and start distributing SAKs.

Replay protection

set interfaces macsec <interface> security replay-window <window>

IEEE 802.1X/MACsec replay protection window. This determines a window in which replay is tolerated, to allow receipt of frames that have been misordered by the network.

- 0: No replay window, strict check
- 1–4294967295: Number of packets that could be misordered

Operation

run generate macsec mka-cak

Generate MKA CAK key

```
vyos@vyos:~$ generate macsec mka-cak
20693b6e08bfa482703a563898c9e3ad
```

run generate macsec mka-ckn

Generate MKA CAK key

```
vyos@vyos:~$ generate macsec mka-ckn
88737efef314ee319b2cbf30210a5f164957d884672c143aefdc0f5f6bc49eb2
```

show interfaces macsec

List all MACsec interfaces

```
vyos@vyos:~$ show interfaces macsec
17: macsec1: protect on validate strict sc off sa off encrypt on send_sci on end_
->station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
20: macsec0: protect on validate strict sc off sa off encrypt off send_sci on_
->end_station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
```

show interfaces macsec <interface>

Show specific MACsec interface information

```
vyos@vyos:~$ show interfaces macsec macsec1
17: macsec1: protect on validate strict sc off sa off encrypt on send_sci on end_
->station off scb off replay off
   cipher suite: GCM-AES-128, using ICV length 16
   TXSC: 005056bfefaa0001 on SA 0
```

Examples

- Two routers connected both via eth1 through an untrusted switch
- R1 has 192.0.2.1/24 & 2001:db8::1/64
- R2 has 192.0.2.2/24 & 2001:db8::2/64

R1

```
set interfaces macsec macsec1 address '192.0.2.1/24'
set interfaces macsec macsec1 address '2001:db8::1/64'
set interfaces macsec macsec1 security cipher 'gcm-aes-128'
set interfaces macsec macsec1 security encrypt
set interfaces macsec macsec1 security mka cak '232e44b7fda6f8e2d88a07bf78a7aff4'
set interfaces macsec macsec1 security mka ckn
->'40916f4b23e3d548ad27eedd2d10c6f98c2d21684699647d63d41b500dfe8836'
set interfaces macsec macsec1 source-interface 'eth1'
```

R2

```

set interfaces macsec macsec1 address '192.0.2.2/24'
set interfaces macsec macsec1 address '2001:db8::2/64'
set interfaces macsec macsec1 security cipher 'gcm-aes-128'
set interfaces macsec macsec1 security encrypt
set interfaces macsec macsec1 security mka cak '232e44b7fda6f8e2d88a07bf78a7aff4'
set interfaces macsec macsec1 security mka ckn
↪ '40916f4b23e3d548ad27eedd2d10c6f98c2d21684699647d63d41b500dfe8836'
set interfaces macsec macsec1 source-interface 'eth1'

```

Pinging (IPv6) the other host and intercepting the traffic in eth1 will show you the content is encrypted.

```

```

8.4.9 OpenVPN

Traditionally hardware routers implement IPsec exclusively due to relative ease of implementing it in hardware and insufficient CPU power for doing encryption in software. Since VyOS is a software router, this is less of a concern. OpenVPN has been widely used on UNIX platform for a long time and is a popular option for remote access VPN, though it's also capable of site-to-site connections.

Advantages of OpenVPN are:

- It uses a single TCP or UDP connection and does not rely on packet source addresses, so it will work even through a double NAT: perfect for public hotspots and such
- It's easy to setup and offers very flexible split tunneling
- There's a variety of client GUI frontends for any platform

Disadvantages are:

- It's slower than IPsec due to higher protocol overhead and the fact it runs in user mode while IPsec, on Linux, is in kernel mode
- None of the operating systems have client software installed by default

In the VyOS CLI, a key point often overlooked is that rather than being configured using the `set vpn` stanza, OpenVPN is configured as a network interface using `set interfaces openvpn`.

Site-To-Site

While many are aware of OpenVPN as a Client VPN solution, it is often overlooked as a site-to-site VPN solution due to lack of support for this mode in many router platforms.

Site-to-site mode supports x.509 but doesn't require it and can also work with static keys, which is simpler in many cases. In this example, we'll configure a simple site-to-site OpenVPN tunnel using a 2048-bit pre-shared key.

First, one of the systems generate the key using the operational command `generate openvpn key <filename>`. This will generate a key with the name provided in the `/config/auth/` directory. Once generated, you will need to copy this key to the remote router.

In our example, we used the filename `openvpn-1.key` which we will reference in our configuration.

- The public IP address of the local side of the VPN will be 198.51.100.10.
- The public IP address of the remote side of the VPN will be 203.0.113.11.
- The tunnel will use 10.255.1.1 for the local IP and 10.255.1.2 for the remote.
- The local site will have a subnet of 10.0.0.0/16.
- The remote site will have a subnet of 10.1.0.0/16.
- Static Routing or other dynamic routing protocols can be used over the vtun interface

- OpenVPN allows for either TCP or UDP. UDP will provide the lowest latency, while TCP will work better for lossy connections; generally UDP is preferred when possible.
- The official port for OpenVPN is 1194, which we reserve for client VPN; we will use 1195 for site-to-site VPN.
- The `persistent-tunnel` directive will allow us to configure tunnel-related attributes, such as firewall policy as we would on any normal network interface.
- If known, the IP of the remote router can be configured using the `remote-host` directive; if unknown, it can be omitted. We will assume a dynamic IP for our remote router.

Local Configuration:

```
set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '203.0.113.11'
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
set interfaces openvpn vtun1 shared-secret-key-file '/config/auth/openvpn-1.key'
set interfaces openvpn vtun1 local-address '10.255.1.1'
set interfaces openvpn vtun1 remote-address '10.255.1.2'
```

Local Configuration - Annotated:

```
set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '203.0.113.11' # Pub
↪IP of other site
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
set interfaces openvpn vtun1 shared-secret-key-file '/config/auth/openvpn-1.key'
set interfaces openvpn vtun1 local-address '10.255.1.1' #
↪Local IP of vtun interface
set interfaces openvpn vtun1 remote-address '10.255.1.2' #
↪Remote IP of vtun interface
```

Remote Configuration:

```
set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '198.51.100.10'
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
set interfaces openvpn vtun1 shared-secret-key-file '/config/auth/openvpn-1.key'
set interfaces openvpn vtun1 local-address '10.255.1.2'
set interfaces openvpn vtun1 remote-address '10.255.1.1'
```

Remote Configuration - Annotated:

```
set interfaces openvpn vtun1 mode site-to-site
set interfaces openvpn vtun1 protocol udp
set interfaces openvpn vtun1 persistent-tunnel
set interfaces openvpn vtun1 remote-host '198.51.100.10' #
↪Pub IP of other site
set interfaces openvpn vtun1 local-port '1195'
set interfaces openvpn vtun1 remote-port '1195'
```

(continues on next page)

(continued from previous page)

```
set interfaces openvpn vtun1 shared-secret-key-file '/config/auth/openvpn-1.key'
set interfaces openvpn vtun1 local-address '10.255.1.2' #
↪Local IP of vtun interface
set interfaces openvpn vtun1 remote-address '10.255.1.1' #
↪Remote IP of vtun interface
```

Firewall Exceptions

For the WireGuard traffic to pass through the WAN interface, you must create a firewall exception.

```
set firewall name OUTSIDE_LOCAL rule 10 action accept
set firewall name OUTSIDE_LOCAL rule 10 description 'Allow established/related'
set firewall name OUTSIDE_LOCAL rule 10 state established enable
set firewall name OUTSIDE_LOCAL rule 10 state related enable
set firewall name OUTSIDE_LOCAL rule 20 action accept
set firewall name OUTSIDE_LOCAL rule 20 description OpenVPN_IN
set firewall name OUTSIDE_LOCAL rule 20 destination port 1195
set firewall name OUTSIDE_LOCAL rule 20 log enable
set firewall name OUTSIDE_LOCAL rule 20 protocol udp
set firewall name OUTSIDE_LOCAL rule 20 source
```

You should also ensure that the OUTSIDE_LOCAL firewall group is applied to the WAN interface and a direction (local).

```
set interfaces ethernet eth0 firewall local name 'OUTSIDE-LOCAL'
```

Static Routing:

Static routes can be configured referencing the tunnel interface; for example, the local router will use a network of 10.0.0.0/16, while the remote has a network of 10.1.0.0/16:

Local Configuration:

```
set protocols static route 10.1.0.0/16 interface vtun1
```

Remote Configuration:

```
set protocols static route 10.0.0.0/16 interface vtun1
```

The configurations above will default to using 256-bit AES in GCM mode for encryption (if both sides support NCP) and SHA-1 for HMAC authentication. SHA-1 is considered weak, but other hashing algorithms are available, as are encryption algorithms:

For Encryption:

This sets the cipher when NCP (Negotiable Crypto Parameters) is disabled or OpenVPN version < 2.4.0.

```
vyos@vyos# set interfaces openvpn vtun1 encryption cipher
Possible completions:
  des          DES algorithm
  3des         DES algorithm with triple encryption
  bf128        Blowfish algorithm with 128-bit key
  bf256        Blowfish algorithm with 256-bit key
  aes128       AES algorithm with 128-bit key CBC
  aes128gcm    AES algorithm with 128-bit key GCM
  aes192       AES algorithm with 192-bit key CBC
```

(continues on next page)

(continued from previous page)

aes192gcm	AES algorithm with 192-bit key GCM
aes256	AES algorithm with 256-bit key CBC
aes256gcm	AES algorithm with 256-bit key GCM

This sets the accepted ciphers to use when version \Rightarrow 2.4.0 and NCP is enabled (which is the default). Default NCP cipher for versions \geq 2.4.0 is aes256gcm. The first cipher in this list is what server pushes to clients.

```
vyos@vyos# set int open vtun0 encryption ncp-ciphers
Possible completions:
des          DES algorithm
3des         DES algorithm with triple encryption
aes128       AES algorithm with 128-bit key CBC
aes128gcm    AES algorithm with 128-bit key GCM
aes192       AES algorithm with 192-bit key CBC
aes192gcm    AES algorithm with 192-bit key GCM
aes256       AES algorithm with 256-bit key CBC
aes256gcm    AES algorithm with 256-bit key GCM
```

For Hashing:

```
vyos@vyos# set interfaces openvpn vtun1 hash
Possible completions:
md5          MD5 algorithm
sha1         SHA-1 algorithm
sha256       SHA-256 algorithm
sha512       SHA-512 algorithm
```

If you change the default encryption and hashing algorithms, be sure that the local and remote ends have matching configurations, otherwise the tunnel will not come up.

Firewall policy can also be applied to the tunnel interface for *local*, *in*, and *out* directions and functions identically to ethernet interfaces.

If making use of multiple tunnels, OpenVPN must have a way to distinguish between different tunnels aside from the pre-shared-key. This is either by referencing IP address or port number. One option is to dedicate a public IP to each tunnel. Another option is to dedicate a port number to each tunnel (e.g. 1195,1196,1197...).

OpenVPN status can be verified using the *show openvpn* operational commands. See the built-in help for a complete list of options.

Server

Multi-client server is the most popular OpenVPN mode on routers. It always uses x.509 authentication and therefore requires a PKI setup. Refer this section **Generate X.509 Certificate and Keys** to generate a CA certificate, a server certificate and key, a certificate revocation list, a Diffie-Hellman key exchange parameters file. You do not need client certificates and keys for the server setup.

In this example we will use the most complicated case: a setup where each client is a router that has its own subnet (think HQ and branch offices), since simpler setups are subsets of it.

Suppose you want to use 10.23.1.0/24 network for client tunnel endpoints and all client subnets belong to 10.23.0.0/20. All clients need access to the 192.168.0.0/16 network.

First we need to specify the basic settings. 1194/UDP is the default. The *persistent-tunnel* option is recommended, it prevents the TUN/TAP device from closing on connection resets or daemon reloads.

Note: Using `openvpn-option -reneg-sec` can be tricky. This option is used to renegotiate data channel after `n` seconds. When used at both server and client, the lower value will trigger the renegotiation. If you set it to 0 on one side of the connection (to disable it), the chosen value on the other side will determine when the renegotiation will occur.

```
set interfaces openvpn vtun10 mode server
set interfaces openvpn vtun10 local-port 1194
set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol udp
```

Then we need to specify the location of the cryptographic materials. Suppose you keep the files in `/config/auth/openvpn`

```
set interfaces openvpn vtun10 tls ca-cert-file /config/auth/openvpn/ca.crt
set interfaces openvpn vtun10 tls cert-file /config/auth/openvpn/server.crt
set interfaces openvpn vtun10 tls key-file /config/auth/openvpn/server.key
set interfaces openvpn vtun10 tls crl-file /config/auth/openvpn/crl.pem
set interfaces openvpn vtun10 tls dh-file /config/auth/openvpn/dh2048.pem
```

Now we need to specify the server network settings. In all cases we need to specify the subnet for client tunnel endpoints. Since we want clients to access a specific network behind our router, we will use a push-route option for installing that route on clients.

```
set interfaces openvpn vtun10 server push-route 192.168.0.0/16
set interfaces openvpn vtun10 server subnet 10.23.1.0/24
```

Since it's a HQ and branch offices setup, we will want all clients to have fixed addresses and we will route traffic to specific subnets through them. We need configuration for each client to achieve this.

Note: Clients are identified by the CN field of their x.509 certificates, in this example the CN is `client0`:

```
set interfaces openvpn vtun10 server client client0 ip 10.23.1.10
set interfaces openvpn vtun10 server client client0 subnet 10.23.2.0/25
```

OpenVPN **will not** automatically create routes in the kernel for client subnets when they connect and will only use client-subnet association internally, so we need to create a route to the 10.23.0.0/20 network ourselves:

```
set protocols static route 10.23.0.0/20 interface vtun10
```

OpenVPN ships with a set of scripts called Easy-RSA that can generate the appropriate files needed for an OpenVPN setup using X.509 certificates. Easy-RSA comes installed by default on VyOS routers.

Copy the Easy-RSA scripts to a new directory to modify the values.

```
cp -r /usr/share/easy-rsa/ /config/my-easy-rsa-config
cd /config/my-easy-rsa-config
```

To ensure the consistent use of values when generating the PKI, set default values to be used by the PKI generating scripts. Rename the `vars.example` filename to `vars`

```
mv vars.example vars
```

Following is the instance of the file after editing. You may also change other values in the file at your discretion/need, though for most cases the defaults should be just fine. (do not leave any of these parameters blank)

```
set_var EASYRSA_DN      "org"
set_var EASYRSA_REQ_COUNTRY "US"
set_var EASYRSA_REQ_PROVINCE "California"
set_var EASYRSA_REQ_CITY "San Francisco"
set_var EASYRSA_REQ_ORG "Copyleft Certificate Co"
set_var EASYRSA_REQ_EMAIL "me@example.net"
set_var EASYRSA_REQ_OU "My Organizational Unit"
set_var EASYRSA_KEY_SIZE 2048
```

init-pki option will create a new pki directory or will delete any previously generated certificates stored in that folder. The term ‘central’ is used to refer server and ‘branch’ for client

Note: Remember the “CA Key Passphrase” prompted in build-ca command, as it will be asked in signing the server/client certificate.

```
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa init-pki
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa build-ca
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa gen-req central nopass
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa sign-req server central
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa gen-dh
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa build-client-full branch1 nopass
```

To generate a certificate revocation list for any client, execute these commands:

```
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa revoke client1
vyos@vyos:/config/my-easy-rsa-config$ ./easyrsa gen-crl
```

Copy the files to /config/auth/openvpn/ to use in OpenVPN tunnel creation

```
vyos@vyos:/config/my-easy-rsa-config$ sudo mkdir /config/auth/openvpn
vyos@vyos:/config/my-easy-rsa-config$ sudo cp pki/ca.crt /config/auth/openvpn
vyos@vyos:/config/my-easy-rsa-config$ sudo cp pki/dh.pem /config/auth/openvpn
vyos@vyos:/config/my-easy-rsa-config$ sudo cp pki/private/central.key /config/auth/
↪openvpn
vyos@vyos:/config/my-easy-rsa-config$ sudo cp pki/issued/central.crt /config/auth/
↪openvpn
vyos@vyos:/config/my-easy-rsa-config$ sudo cp pki/crl.pem /config/auth/openvpn
```

Additionally, each client needs a copy of ca.crt and its own client key and cert files. The files are plaintext so they may be copied either manually, or through a remote file transfer tool like scp. Whichever method you use, the files need to end up in the proper location on each router. For example, Branch 1’s router might have the following files:

```
vyos@branch1-rtr:$ ls /config/auth/openvpn
ca.crt branch1.crt branch1.key
```

Client Authentication

Enterprise installations usually ship a kind of directory service which is used to have a single password store for all employees. VyOS and OpenVPN support using LDAP/AD as single user backend.

Authentication is done by using the openvpn-auth-ldap.so plugin which is shipped with every VyOS installation. A dedicated configuration file is required. It is best practise to store it in /config to survive image updates

```
set interfaces openvpn vtun0 openvpn-option "--plugin /usr/lib/openvpn/openvpn-auth-
↳ldap.so /config/auth/ldap-auth.config"
```

The required config file may look like this:

```
<LDAP>
# LDAP server URL
URL ldap://ldap.example.com
# Bind DN (If your LDAP server doesn't support anonymous binds)
BindDN cn=LDAPUser,dc=example,dc=com
# Bind Password password
Password S3cr3t
# Network timeout (in seconds)
Timeout 15
</LDAP>

<Authorization>
# Base DN
BaseDN "ou=people,dc=example,dc=com"
# User Search Filter
SearchFilter "(&(uid=%u)(objectClass=shadowAccount))"
# Require Group Membership - allow all users
RequireGroup false
</Authorization>
```

Despite the fact that AD is a superset of LDAP

```
<LDAP>
# LDAP server URL
URL ldap://dc01.example.com
# Bind DN (If your LDAP server doesn't support anonymous binds)
BindDN CN=LDAPUser,DC=example,DC=com
# Bind Password
Password mysecretpassword
# Network timeout (in seconds)
Timeout 15
# Enable Start TLS
TLSEnable no
# Follow LDAP Referrals (anonymously)
FollowReferrals no
</LDAP>

<Authorization>
# Base DN
BaseDN "DC=example,DC=com"
# User Search Filter, user must be a member of the VPN AD group
SearchFilter "(&(sAMAccountName=%u)(memberOf=CN=VPN,OU=Groups,DC=example,DC=com))"
# Require Group Membership
RequireGroup false # already handled by SearchFilter
<Group>
BaseDN "OU=Groups,DC=example,DC=com"
SearchFilter "(|(cn=VPN))"
MemberAttribute memberOf
</Group>
</Authorization>
```

If you only want to check if the user account is enabled and can authenticate (against the primary group) the following snippet is sufficient:

```

<LDAP>
  URL ldap://dc01.example.com
  BindDN CN=SA_OPENVPN,OU=ServiceAccounts,DC=example,DC=com
  Password ThisIsTopSecret
  Timeout 15
  TLSEnable no
  FollowReferrals no
</LDAP>

<Authorization>
  BaseDN "DC=example,DC=com"
  SearchFilter "sAMAccountName=%u"
  RequireGroup false
</Authorization>

```

A complete LDAP auth OpenVPN configuration could look like the following example:

```

vyos@vyos# show interfaces openvpn
openvpn vtun0 {
  mode server
  openvpn-option "--tun-mtu 1500 --fragment 1300 --mssfix"
  openvpn-option "--plugin /usr/lib/openvpn/openvpn-auth-ldap.so /config/auth/ldap-
→auth.config"
  openvpn-option "--push redirect-gateway"
  openvpn-option --duplicate-cn
  openvpn-option --client-cert-not-required
  openvpn-option --comp-lzo
  openvpn-option --persist-key
  openvpn-option --persist-tun
  server {
    domain-name example.com
    max-connections 5
    name-server 203.0.113.0.10
    name-server 198.51.100.3
    subnet 172.18.100.128/29
  }
  tls {
    ca-cert-file /config/auth/ca.crt
    cert-file /config/auth/server.crt
    dh-file /config/auth/dh1024.pem
    key-file /config/auth/server.key
  }
}

```

Client

VyOS can not only act as an OpenVPN site-to-site or server for multiple clients. You can indeed also configure any VyOS OpenVPN interface as an OpenVPN client connecting to a VyOS OpenVPN server or any other OpenVPN server.

Given the following example we have one VyOS router acting as OpenVPN server and another VyOS router acting as OpenVPN client. The server also pushes a static client IP address to the OpenVPN client. Remember, clients are identified using their CN attribute in the SSL certificate.

```

set interfaces openvpn vtun10 encryption cipher 'aes256'
set interfaces openvpn vtun10 hash 'sha512'

```

(continues on next page)

(continued from previous page)

```

set interfaces openvpn vtun10 local-host '172.18.201.10'
set interfaces openvpn vtun10 local-port '1194'
set interfaces openvpn vtun10 mode 'server'
set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol 'udp'
set interfaces openvpn vtun10 server client client1 ip '10.10.0.10'
set interfaces openvpn vtun10 server domain-name 'vyos.net'
set interfaces openvpn vtun10 server max-connections '250'
set interfaces openvpn vtun10 server name-server '172.16.254.30'
set interfaces openvpn vtun10 server subnet '10.10.0.0/24'
set interfaces openvpn vtun10 server topology 'subnet'
set interfaces openvpn vtun10 tls ca-cert-file '/config/auth/ca.crt'
set interfaces openvpn vtun10 tls cert-file '/config/auth/server.crt'
set interfaces openvpn vtun10 tls dh-file '/config/auth/dh.pem'
set interfaces openvpn vtun10 tls key-file '/config/auth/server.key'
set interfaces openvpn vtun10 use-lzo-compression

```

```

set interfaces openvpn vtun10 encryption cipher 'aes256'
set interfaces openvpn vtun10 hash 'sha512'
set interfaces openvpn vtun10 mode 'client'
set interfaces openvpn vtun10 persistent-tunnel
set interfaces openvpn vtun10 protocol 'udp'
set interfaces openvpn vtun10 remote-host '172.18.201.10'
set interfaces openvpn vtun10 remote-port '1194'
set interfaces openvpn vtun10 tls ca-cert-file '/config/auth/ca.crt'
set interfaces openvpn vtun10 tls cert-file '/config/auth/client1.crt'
set interfaces openvpn vtun10 tls key-file '/config/auth/client1.key'
set interfaces openvpn vtun10 use-lzo-compression

```

Options

We do not have CLI nodes for every single OpenVPN option. If an option is missing, a feature request should be opened at [Phabricator](#) so all users can benefit from it (see [Issues/Feature requests](#)).

If you are a hacker or want to try on your own we support passing raw OpenVPN options to OpenVPN.

```
set interfaces openvpn vtun10 openvpn-option 'persistent-key'
```

Will add `persistent-key` at the end of the generated OpenVPN configuration. Please use this only as last resort - things might break and OpenVPN won't start if you pass invalid options/syntax.

```
set interfaces openvpn vtun10 openvpn-option 'push "keepalive 1 10";'
```

Will add `push "keepalive 1 10"` to the generated OpenVPN config file.

Note: Sometimes option lines in the generated OpenVPN configuration require quotes. This is done through a hack on our config generator. You can pass quotes using the `";` statement.

Troubleshooting

VyOS provides some operational commands on OpenVPN.

The following commands let you check tunnel status.

```
show openvpn client
```

Use this command to check the tunnel status for OpenVPN client interfaces.

show openvpn server

Use this command to check the tunnel status for OpenVPN server interfaces.

show openvpn site-to-site

Use this command to check the tunnel status for OpenVPN site-to-site interfaces.

The following commands let you reset OpenVPN.

reset openvpn client <text>

Use this command to reset the specified OpenVPN client.

reset openvpn interface <interface>

Use this command to reset the OpenVPN process on a specific interface.

8.4.10 WireGuard

WireGuard is an extremely simple yet fast and modern VPN that utilizes state-of-the-art cryptography. See <https://www.wireguard.com> for more information.

Site to Site VPN

This diagram corresponds with the example site to site configuration below.

Configuration

Keypairs

WireGuard requires the generation of a keypair, which includes a private key to decrypt incoming traffic, and a public key for peer(s) to encrypt traffic.

Generate Keypair

generate wireguard default-keypair

It generates the keypair, which includes the public and private parts, and stores it within VyOS. It will be used per default on any configured WireGuard interface, even if multiple interfaces are being configured.

show wireguard keypairs pubkey default

It shows the public key to be shared with your peer(s). Your peer will encrypt all traffic to your system using this public key.

```
vyos@vyos:~$ show wireguard keypairs pubkey default
hW17UxY7zeydJNPIyo3UtGnBHkzTK/NeBOrDSIU9Tx0=
```

Generate Named Keypair

Named keypairs can be used on a interface basis when configured. If multiple WireGuard interfaces are being configured, each can have their own keypairs.

generate wireguard named-keypairs <name>

The commands below generates 2 keypairs unrelated to each other.

```
vyos@vyos:~$ generate wireguard named-keypairs KP01
vyos@vyos:~$ generate wireguard named-keypairs KP02
```

Interface configuration

The next step is to configure your local side as well as the policy based trusted destination addresses. If you only initiate a connection, the listen port and address/port is optional; however, if you act like a server and endpoints initiate the connections to your system, you need to define a port your clients can connect to, otherwise the port is randomly chosen and may make connection difficult with firewall rules, since the port may be different each time the system is rebooted.

You will also need the public key of your peer as well as the network(s) you want to tunnel (allowed-ips) to configure a WireGuard tunnel. The public key below is always the public key from your peer, not your local one.

local side - commands

```
set interfaces wireguard wg01 address '10.1.0.1/30'
set interfaces wireguard wg01 description 'VPN-to-wg02'
set interfaces wireguard wg01 peer to-wg02 allowed-ips '192.168.2.0/24'
set interfaces wireguard wg01 peer to-wg02 address '<Site1 Pub IP>'
set interfaces wireguard wg01 peer to-wg02 port '51820'
set interfaces wireguard wg01 peer to-wg02 pubkey
↪ 'XMrlPykaxhdAAiSjhtPlvi30NVkvLQliQuKP7AI7CyI='
```

(continues on next page)

(continued from previous page)

```
set interfaces wireguard wg01 port '51820'
set protocols static route 192.168.2.0/24 interface wg01
```

local side - annotated commands

```
set interfaces wireguard wg01 address '10.1.0.1/30'           # Address of
↳the wg01 tunnel interface.
set interfaces wireguard wg01 description 'VPN-to-wg02'
set interfaces wireguard wg01 peer to-wg02 allowed-ips '192.168.2.0/24' # Subnets
↳that are allowed to travel over the tunnel
set interfaces wireguard wg01 peer to-wg02 address '<Site2 Pub IP>' # Public IP
↳of the peer
set interfaces wireguard wg01 peer to-wg02 port '58120'       # Port of the
↳Peer
set interfaces wireguard wg01 peer to-wg02 pubkey '<pubkey>'   # Public Key
↳of the Peer
set interfaces wireguard wg01 port '51820'                   # Port of own
↳server
set protocols static route 192.168.2.0/24 interface wg01     # Static
↳route to remote subnet
```

The last step is to define an interface route for 10.2.0.0/24 to get through the WireGuard interface *wg01*. Multiple IPs or networks can be defined and routed. The last check is allowed-ips which either prevents or allows the traffic.

Note: You can not assign the same allowed-ips statement to multiple WireGuard peers. This a design decision. For more information please check the [WireGuard mailing list](#).

set interfaces wireguard <interface> private-key <name>

To use a named key on an interface, the option private-key needs to be set.

```
set interfaces wireguard wg01 private-key KP01
```

The command `show wireguard keypairs pubkey KP01` will then show the public key, which needs to be shared with the peer.

remote side - commands

```
set interfaces wireguard wg01 address '10.1.0.2/30'
set interfaces wireguard wg01 description 'VPN-to-wg01'
set interfaces wireguard wg01 peer to-wg02 allowed-ips '192.168.1.0/24'
set interfaces wireguard wg01 peer to-wg02 address '<Site1 Pub IP>'
set interfaces wireguard wg01 peer to-wg02 port '51820'
set interfaces wireguard wg01 peer to-wg02 pubkey
↳'u41jO3OF73Gq1WARMFG7tOfk7+r8o8AzPxJlFZRhzk='
set interfaces wireguard wg01 port '51820'
set protocols static route 192.168.1.0/24 interface wg01
```

remote side - annotated commands

```
set interfaces wireguard wg01 address '10.1.0.2/30'           # Address of
↳the wg01 tunnel interface.
set interfaces wireguard wg01 description 'VPN-to-wg01'
set interfaces wireguard wg01 peer to-wg02 allowed-ips '192.168.1.0/24' # Subnets
↳that are allowed to travel over the tunnel
set interfaces wireguard wg01 peer to-wg02 address 'Site1 Pub IP' # Public IP
↳address of the Peer
```

(continues on next page)

(continued from previous page)

```

set interfaces wireguard wg01 peer to-wg02 port '51820'           # Port of the
↪Peer
set interfaces wireguard wg01 peer to-wg02 pubkey '<pubkey>'       # Public key
↪of the Peer
set interfaces wireguard wg01 port '51820'                       # Port of own
↪server
set protocols static route 192.168.1.0/24 interface wg01         # Static
↪route to remote subnet

```

Firewall Exceptions

For the WireGuard traffic to pass through the WAN interface, you must create a firewall exception.

```

set firewall name OUTSIDE_LOCAL rule 10 action accept
set firewall name OUTSIDE_LOCAL rule 10 description 'Allow established/related'
set firewall name OUTSIDE_LOCAL rule 10 state established enable
set firewall name OUTSIDE_LOCAL rule 10 state related enable
set firewall name OUTSIDE_LOCAL rule 20 action accept
set firewall name OUTSIDE_LOCAL rule 20 description WireGuard_IN
set firewall name OUTSIDE_LOCAL rule 20 destination port 51820
set firewall name OUTSIDE_LOCAL rule 20 log enable
set firewall name OUTSIDE_LOCAL rule 20 protocol udp
set firewall name OUTSIDE_LOCAL rule 20 source

```

You should also ensure that the OUTSIDE_LOCAL firewall group is applied to the WAN interface and a direction (local).

```

set interfaces ethernet eth0 firewall local name 'OUTSIDE-LOCAL'

```

Assure that your firewall rules allow the traffic, in which case you have a working VPN using WireGuard.

```

wg01# ping 192.168.1.1
PING 192.168.1.1 (192.168.1.1) 56(84) bytes of data.
64 bytes from 192.168.1.1: icmp_seq=1 ttl=64 time=1.16 ms
64 bytes from 192.168.1.1: icmp_seq=2 ttl=64 time=1.77 ms

wg02# ping 192.168.2.1
PING 192.168.2.1 (192.168.2.1) 56(84) bytes of data.
64 bytes from 192.168.2.1: icmp_seq=1 ttl=64 time=4.40 ms
64 bytes from 192.168.2.1: icmp_seq=2 ttl=64 time=1.02 ms

```

An additional layer of symmetric-key crypto can be used on top of the asymmetric crypto. This is optional.

```

wg01# run generate wireguard preshared-key
rvVDOoc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc=

```

Copy the key, as it is not stored on the local filesystem. Because it is a symmetric key, only you and your peer should have knowledge of its content. Make sure you distribute the key in a safe manner,

```

wg01# set interfaces wireguard wg01 peer to-wg02 preshared-key
↪'rvVDOoc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc='
wg02# set interfaces wireguard wg01 peer to-wg01 preshared-key
↪'rvVDOoc2IYEnV+k5p7TNAmHBMEGTHbPU8Qqg8c/sUqc='

```

Remote Access “RoadWarrior” Example

With WireGuard, a Road Warrior VPN config is similar to a site-to-site VPN. It just lacks the address and port statements.

In the following example, the IPs for the remote clients are defined in the peers. This allows the peers to interact with one another.

```
wireguard wg0 {
    address 10.172.24.1/24
    address 2001:DB8:470:22::1/64
    description RoadWarrior
    peer MacBook {
        allowed-ips 10.172.24.30/32
        allowed-ips 2001:DB8:470:22::30/128
        persistent-keepalive 15
        pubkey F5MbW7ye7DsoxdOaixjdrudshjjxN5UdNV+pGFHqehc=
    }
    peer iPhone {
        allowed-ips 10.172.24.20/32
        allowed-ips 2001:DB8:470:22::20/128
        persistent-keepalive 15
        pubkey BknHcLFo8nOo8Dwq2CjaC/TedchKQ0ebxC7GYn7A100=
    }
    port 2224
}
```

The following is the config for the iPhone peer above. It’s important to note that the AllowedIPs wildcard setting directs all IPv4 and IPv6 traffic through the connection.

```
[Interface]
PrivateKey = ARAKLSDJsadlkfjasdfiowqgeruriowqeasdf=
Address = 10.172.24.20/24, 2001:DB8:470:22::20/64
DNS = 10.0.0.53, 10.0.0.54

[Peer]
PublicKey = RIbtUTCfgzNjnLNPQ/ulkGnnB2vMWHm7l2H/xUfbyjc=
AllowedIPs = 0.0.0.0/0, ::/0
Endpoint = 192.0.2.1:2224
PersistentKeepalive = 25
```

However, split-tunneling can be achieved by specifying the remote subnets. This ensures that only traffic destined for the remote site is sent over the tunnel. All other traffic is unaffected.

```
[Interface]
PrivateKey = 8IasdfweirousdlEVGUk5XsT+wYFZ9mhPnQhmjzaJE6Go=
Address = 10.172.24.30/24, 2001:DB8:470:22::30/64

[Peer]
PublicKey = RIbtUTCfgzNjnLNPQ/ulkGnnB2vMWHm7l2H/xUfbyjc=
AllowedIPs = 10.172.24.30/24, 2001:DB8:470:22::/64
Endpoint = 192.0.2.1:2224
PersistentKeepalive = 25
```

Operational Commands

Status

show interfaces wireguard wg0 summary

Show info about the Wireguard service. It also shows the latest handshake.

```
vyos@vyos:~$ show interfaces wireguard wg0 summary
interface: wg0
  public key:
  private key: (hidden)
  listening port: 51820

peer: <peer pubkey>
  endpoint: <peer public IP>
  allowed ips: 10.69.69.2/32
  latest handshake: 23 hours, 45 minutes, 26 seconds ago
  transfer: 1.26 MiB received, 6.47 MiB sent
```

show interfaces wireguard

Get a list of all wireguard interfaces

```
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
wg0             10.0.0.1/24     u/u
```

show interfaces wireguard <interface>

Show general information about specific WireGuard interface

```
vyos@vyos:~$ show interfaces wireguard wg01
interface: wg0
  address: 10.0.0.1/24
  public key: h1HkYlSuHdJN6Qv4Hz4bBzjGg5WUty+U1L7DJsZyliE=
  private key: (hidden)
  listening port: 41751

      RX:  bytes  packets  errors  dropped  overrun      mcast
           0         0         0         0         0           0
      TX:  bytes  packets  errors  dropped  carrier  collisions
           0         0         0         0         0           0
```

Encryption Keys

show wireguard keypair pubkey <name>

Show public key portion for specified key. This can be either the default key, or any other named key-pair.

The default keypair

```
vyos@vyos:~$ show wireguard keypair pubkey default
FAXCPb6EbTlSH5200J5zTopt9AYXneBthAySPBLbZwM=
```

Name keypair KP01

```
vyos@vyos:~$ show wireguard keypair pubkey KP01
HUtsu198toEnmlpoGoRTyqkUKfKUdyh54f45dtcahDM=
```

delete wireguard keypair pubkey <name>

Delete a keypair, this can be either the `default` key, or any other named key-pair.

```
vyos@vyos:~$ delete wireguard keypair default
```

Remote Access “RoadWarrior” clients

Some users tend to connect their mobile devices using WireGuard to their VyOS router. To ease deployment one can generate a “per mobile” configuration from the VyOS CLI.

Warning: From a security perspective, it is not recommended to let a third party create and share the private key for a secured connection. You should create the private portion on your own and only hand out the public key. Please keep this in mind when using this convenience feature.

generate wireguard client-config <name> interface <interface> server <ip|fqdn> address <client-ip>

Using this command, you will create a new client configuration which can connect to `interface` on this router. The public key from the specified interface is automatically extracted and embedded into the configuration.

The command also generates a configuration snippet which can be copy/pasted into the VyOS CLI if needed. The supplied `<name>` on the CLI will become the peer name in the snippet.

In addition you will specify the IP address or FQDN for the client where it will connect to. The address parameter can be used up to two times and is used to assign the clients specific IPv4 (/32) or IPv6 (/128) address.

8.4.11 PPPoE

PPPoE (Point-to-Point Protocol over Ethernet) is a network protocol for encapsulating PPP frames inside Ethernet frames. It appeared in 1999, in the context of the boom of DSL as the solution for tunneling packets over the DSL connection to the ISPs (Internet Service Providers) IP network, and from there to the rest of the Internet. A 2005 networking book noted that “Most DSL providers use PPPoE, which provides authentication, encryption, and compression.” Typical use of PPPoE involves leveraging the PPP facilities for authenticating the user with a username and password, predominately via the PAP protocol and less often via CHAP.

Operating Modes

VyOS supports setting up PPPoE in two different ways to a PPPoE internet connection. This is because most ISPs provide a modem that is also a wireless router.

Home Users

In this method, the DSL Modem/Router connects to the ISP for you with your credentials preprogrammed into the device. This gives you an **RFC 1918** address, such as `192.168.1.0/24` by default.

For a simple home network using just the ISP’s equipment, this is usually desirable. But if you want to run VyOS as your firewall and router, this will result in having a double NAT and firewall setup. This results in a few extra layers of complexity, particularly if you use some NAT or tunnel features.

WireGuard client configuration for interface: wg0

To enable this configuration on a VyOS router you can use the following commands:

=== VyOS (server) configuration ===

```
set interfaces wireguard wg0 peer foo allowed-ips '10.0.1.10/32'  
set interfaces wireguard wg0 peer foo allowed-ips '2001:db8::10/128'  
set interfaces wireguard wg0 peer foo pubkey 'Hk62WnBsZawKaBnucwmI8ZHZs6ABnr5M8OAC6vch/F4='
```

=== RoadWarrior (client) configuration ===

[Interface]

```
PrivateKey = kLlYfiTO+VrF8rzoBIsl9DrylDniwJUQie5jwWIXLFs=  
Address = 10.0.1.10/32, 2001:db8::10/128  
DNS = 1.1.1.1
```

[Peer]

```
PublicKey = h1HkYlSuHdJN6Qv4Hz4bBzjGg5WUty+U1L7DJs2yliE=  
Endpoint = wireguard.vyos.net:41751  
AllowedIPs = 0.0.0.0/0, ::/0
```

Business Users

In order to have full control and make use of multiple static public IP addresses, your VyOS will have to initiate the PPPoE connection and control it. In order for this method to work, you will have to figure out how to make your DSL Modem/Router switch into a Bridged Mode so it only acts as a DSL Transceiver device to connect between the Ethernet link of your VyOS and the phone cable. Once your DSL Transceiver is in Bridge Mode, you should get no IP address from it. Please make sure you connect to the Ethernet Port 1 if your DSL Transceiver has a switch, as some of them only work this way.

Once you have an Ethernet device connected, i.e. *eth0*, then you can configure it to open the PPPoE session for you and your DSL Transceiver (Modem/Router) just acts to translate your messages in a way that vDSL/aDSL understands.

Configuration

Common interface configuration

set interfaces pppoe <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces pppoe pppoe0 description 'This is an awesome interface running on
↳VyOS'
```

set interfaces pppoe <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pppoe pppoe0 disable
```

set interfaces pppoe <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pppoe pppoe0 vrf red
```

PPPoE options

set interfaces pppoe <interface> access-concentrator <name>

Use this command to restrict the PPPoE session on a given access concentrator. Normally, a host sends a PPPoE initiation packet to start the PPPoE discovery process, a number of access concentrators respond with offer packets and the host selects one of the responding access concentrators to serve this session.

This command allows you to select a specific access concentrator when you know the access concentrators <name>.

set interfaces pppoe <interface> authentication user <username>

Use this command to set the username for authenticating with a remote PPPoE endpoint. Authentication is optional from the system's point of view but most service providers require it.

```
set interfaces pppoe <interface> authentication password <password>
```

Use this command to set the password for authenticating with a remote PPPoE endpoint. Authentication is optional from the system's point of view but most service providers require it.

```
set interfaces pppoe <interface> connect-on-demand
```

When set the interface is enabled for "dial-on-demand".

Use this command to instruct the system to establish a PPPoE connection automatically once traffic passes through the interface. A disabled on-demand connection is established at boot time and remains up. If the link fails for any reason, the link is brought back up immediately.

Enabled on-demand PPPoE connections bring up the link only when traffic needs to pass this link. If the link fails for any reason, the link is brought back up automatically once traffic passes the interface again. If you configure an on-demand PPPoE connection, you must also configure the idle timeout period, after which an idle PPPoE link will be disconnected. A non-zero idle timeout will never disconnect the link after it first came up.

```
set interfaces pppoe <interface> default-route [auto | force | none]
```

Use this command to specify whether to automatically add a default route pointing to the endpoint of the PPPoE when the link comes up. The default route is only added if no other default route already exists in the system.

default: A default route to the remote endpoint is automatically added when the link comes up (i.e. auto).

- auto: A default route is added if no other default route (From any source) already exists.
- force: A default route is added after removing *all* existing default routes.
- none: No default route is installed.

Note: In all modes except 'none', all default routes using this interface will be removed when the interface is torn down - even manually installed static routes.

```
set interfaces pppoe <interface> idle-timeout <time>
```

Use this command to set the idle timeout interval to be used with on-demand PPPoE sessions. When an on-demand connection is established, the link is brought up only when traffic is sent and is disabled when the link is idle for the interval specified.

If this parameter is not set or 0, an on-demand link will not be taken down when it is idle and after the initial establishment of the connection. It will stay up forever.

```
set interfaces pppoe <interface> local-address <address>
```

Use this command to set the IP address of the local endpoint of a PPPoE session. If it is not set it will be negotiated.

```
set interfaces pppoe <interface> mtu <mtu>
```

Configure MTU on given *<interface>*. It is the size (in bytes) of the largest ethernet frame sent on this link.

```
set interfaces pppoe <interface> no-peer-dns
```

Use this command to not install advertised DNS nameservers into the local system.

```
set interfaces pppoe <interface> remote-address <address>
```

Use this command to set the IP address of the remote endpoint of a PPPoE session. If it is not set it will be negotiated.

```
set interfaces pppoe <interface> service-name <name>
```

Use this command to specify a service name by which the local PPPoE interface can select access concentrators to connect with. It will connect to any access concentrator if not set.

```
set interfaces pppoe <interface> source-interface <source-interface>
```

Use this command to link the PPPoE connection to a physical interface. Each PPPoE connection must be established over a physical interface. Interfaces can be regular Ethernet interfaces, VIFs or bonding interfaces/VIFs.

IPv6

```
set interfaces pppoe <interface> ipv6 address autoconf
```

Use this command to enable acquisition of IPv6 address using stateless autoconfig (SLAAC).

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces pppoe <interface> dhcpv6-options pd <id> length <length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 length 56
```

```
set interfaces pppoe <interface> dhcpv6-options pd <id> interface <delegatee>  
address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth8 address 65534
```

```
set interfaces pppoe <interface> dhcpv6-options pd <id> interface <delegatee>  
sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Operation

show interfaces pppoe <interface>

Show detailed information on given <interface>

```
vyos@vyos:~$ show interfaces pppoe pppoe0
pppoe0: <POINTOPOINT,MULTICAST,NOARP,UP,LOWER_UP> mtu 1492 qdisc pfifo_fast_
↪state UNKNOWN group default qlen 3
    link/ppp

```

show interfaces pppoe <interface> queue

Displays queue information for a PPPoE interface.

```
vyos@vyos:~$ show interfaces pppoe pppoe0 queue
qdisc pfifo_fast 0: root refcnt 2 bands 3 priomap  1 2 2 2 1 2 0 0 1 1 1 1 1 1 1_

backlog 0b 0p requeues 0
```

Connect/Disconnect

disconnect interface <interface>

Test disconnecting given connection-oriented interface. <interface> can be pppoe0 as the example.

connect interface <interface>

Test connecting given connection-oriented interface. <interface> can be pppoe0 as the example.

Example

Requirements:

- Your ISP's modem is connected to port `eth0` of your VyOS box.
- No VLAN tagging required by your ISP.
- You need your PPPoE credentials from your DSL ISP in order to configure this. The usual username is in the form of `name@host.net` but may vary depending on ISP.
- The largest MTU size you can use with DSL is 1492 due to PPPoE overhead. If you are switching from a DHCP based ISP like cable then be aware that things like VPN links may need to have their MTU sizes adjusted to work within this limit.
- With the `default-route` option set to `auto`, VyOS will only add the default gateway you receive from your DSL ISP to the routing table if you have no other WAN connections. If you wish to use a dual WAN connection, change the `default-route` option to `force`. You could also install a static route and set the `default-route` option to `none`.

- With the `name-server` option set to `none`, VyOS will ignore the nameservers your ISP sends you and thus you can fully rely on the ones you have configured statically.

Note: Syntax has changed from VyOS 1.2 (crux) and it will be automatically migrated during an upgrade.

```
set interfaces pppoe pppoe0 default-route 'auto'
set interfaces pppoe pppoe0 mtu 1492
set interfaces pppoe pppoe0 authentication user 'userid'
set interfaces pppoe pppoe0 authentication password 'secret'
set interfaces pppoe pppoe0 source-interface 'eth0'
```

You should add a firewall to your configuration above as well by assigning it to the pppoe0 itself as shown here:

```
set interfaces pppoe pppoe0 firewall in name NET-IN
set interfaces pppoe pppoe0 firewall local name NET-LOCAL
set interfaces pppoe pppoe0 firewall out name NET-OUT
```

VLAN Example

Some recent ISPs require you to build the PPPoE connection through a VLAN interface. One of those ISPs is e.g. Deutsche Telekom in Germany. VyOS can easily create a PPPoE session through an encapsulated VLAN interface. The following configuration will run your PPPoE connection through VLAN7 which is the default VLAN for Deutsche Telekom:

```
set interfaces pppoe pppoe0 default-route 'auto'
set interfaces pppoe pppoe0 mtu 1492
set interfaces pppoe pppoe0 authentication user 'userid'
set interfaces pppoe pppoe0 authentication password 'secret'
set interfaces pppoe pppoe0 source-interface 'eth0.7'
```

IPv6 DHCPv6-PD Example

The following configuration will assign a /64 prefix out of a /56 delegation to eth0. The IPv6 address assigned to eth0 will be <prefix>::ffff/64. If you do not know the prefix size delegated to you, start with `sla-len 0`.

```
set interfaces pppoe pppoe0 authentication user vyos
set interfaces pppoe pppoe0 authentication password vyos
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth0 address '1'
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth0 sla-id '0'
set interfaces pppoe pppoe0 dhcpv6-options pd 0 length '56'
set interfaces pppoe pppoe0 ipv6 address autoconf
set interfaces pppoe pppoe0 source-interface eth1
```

8.4.12 MACVLAN - Pseudo Ethernet

Pseudo-Ethernet or MACVLAN interfaces can be seen as subinterfaces to regular ethernet interfaces. Each and every subinterface is created a different media access control (MAC) address, for a single physical Ethernet port. Pseudo-Ethernet interfaces have most of their application in virtualized environments,

By using Pseudo-Ethernet interfaces there will be less system overhead compared to running a traditional bridging approach. Pseudo-Ethernet interfaces can also be used to workaround the general limit of 4096 virtual LANs (VLANs) per physical Ethernet port, since that limit is with respect to a single MAC address.

Every Virtual Ethernet interfaces behaves like a real Ethernet interface. They can have IPv4/IPv6 addresses configured, or can request addresses by DHCP/ DHCPv6 and are associated/mapped with a real ethernet port. This also makes Pseudo-Ethernet interfaces interesting for testing purposes. A Pseudo-Ethernet device will inherit characteristics (speed, duplex, ...) from its physical parent (the so called link) interface.

Once created in the system, Pseudo-Ethernet interfaces can be referenced in the exact same way as other Ethernet interfaces. Notes about using Pseudo- Ethernet interfaces:

- Pseudo-Ethernet interfaces can not be reached from your internal host. This means that you can not try to ping a Pseudo-Ethernet interface from the host system on which it is defined. The ping will be lost.
- Loopbacks occurs at the IP level the same way as for other interfaces, ethernet frames are not forwarded between Pseudo-Ethernet interfaces.
- Pseudo-Ethernet interfaces may not work in environments which expect a NIC (Network Interface Card) to only have a single address. This applies to: - VMware machines using default settings - Network switches with security settings allowing only a single MAC address - xDSL modems that try to learn the MAC address of the NIC

Configuration

Common interface configuration

set interfaces pseudo-ethernet <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces pseudo-ethernet peth0 address 192.0.2.1/24
set interfaces pseudo-ethernet peth0 address 2001:db8::1/64
set interfaces pseudo-ethernet peth0 address dhcp
set interfaces pseudo-ethernet peth0 address dhcpv6
```

set interfaces pseudo-ethernet <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the show interfaces command or SNMP based monitoring tools.

Example:

```
set interfaces pseudo-ethernet peth0 description 'This is an awesome interface_
↳running on VyOS'
```

set interfaces pseudo-ethernet <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pseudo-ethernet peth0 disable
```

set interfaces pseudo-ethernet <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces pseudo-ethernet peth0 disable-flow-control
```

set interfaces pseudo-ethernet <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces pseudo-ethernet peth0 disable-link-detect
```

set interfaces pseudo-ethernet <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces pseudo-ethernet peth0 mac '00:01:02:03:04:05'
```

set interfaces pseudo-ethernet <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces pseudo-ethernet peth0 mtu 9000
```

set interfaces pseudo-ethernet <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces pseudo-ethernet peth0 ip arp-cache-timeout 180
```

set interfaces pseudo-ethernet <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned

by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces pseudo-ethernet peth0 ip disable-arp-filter
```

set interfaces pseudo-ethernet <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces pseudo-ethernet peth0 ip disable-forwarding
```

set interfaces pseudo-ethernet <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-accept
```

set interfaces pseudo-ethernet <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-announce
```

set interfaces pseudo-ethernet <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces pseudo-ethernet peth0 ip enable-arp-ignore
```

set interfaces pseudo-ethernet <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on

subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces pseudo-ethernet peth0 ip enable-proxy-arp
```

set interfaces pseudo-ethernet <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces pseudo-ethernet <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces pseudo-ethernet <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address autoconf
```

set interfaces pseudo-ethernet <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces pseudo-ethernet <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 address no-default-link-local
```

set interfaces pseudo-ethernet <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces pseudo-ethernet peth0 ipv6 disable-forwarding
```

set interfaces pseudo-ethernet <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pseudo-ethernet peth0 vrf red
```

DHCP(v6)

**set interfaces pseudo-ethernet <interface> dhcp-options client-id
<description>**

[RFC 2131](#) states: The client MAY choose to explicitly provide the identifier through the 'client identifier' option. If the client supplies a 'client identifier', the client MUST use the same 'client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options client-id 'foo-bar'
```

set interfaces pseudo-ethernet <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options host-name 'VyOS'
```

**set interfaces pseudo-ethernet <interface> dhcp-options vendor-class-id
<vendor-id>**

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces pseudo-ethernet <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options no-default-route
```

set interfaces pseudo-ethernet <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options default-route-distance 220
```

set interfaces pseudo-ethernet <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces pseudo-ethernet peth0 dhcp-options reject 192.168.100.0/24
```

set interfaces pseudo-ethernet <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces pseudo-ethernet peth0 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces pseudo-ethernet <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options parameters-only
```

set interfaces pseudo-ethernet <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options rapid-commit
```

set interfaces pseudo-ethernet <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

```
set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> length
<length>
```

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 length 56
```

```
set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> interface
<delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 interface eth8 address
↪65534
```

```
set interfaces pseudo-ethernet <interface> dhcpv6-options pd <id> interface
<delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pseudo-ethernet peth0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Pseudo Ethernet/MACVLAN options

```
set interfaces pseudo-ethernet <interface> source-interface <ethX>
```

Specifies the physical <ethX> Ethernet interface associated with a Pseudo Ethernet <interface>.

VLAN

IEEE [802.1q](#), often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions

for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

set interfaces pseudo-ethernet <interface> vif <vlan-id>

Create a new VLAN interface on interface `<interface>` using the VLAN number provided via `<vlan-id>`.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

Note: Only 802.1Q-tagged packets are accepted on Ethernet vifs.

set interfaces pseudo-ethernet <interface> vif <vlan-id> address <address | dhcp | dhcpv6>

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 address 192.0.2.1/24
set interfaces pseudo-ethernet peth0 vif 10 address 2001:db8::1/64
set interfaces pseudo-ethernet peth0 vif 10 address dhcp
set interfaces pseudo-ethernet peth0 vif 10 address dhcpv6
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 description 'This is an awesome_
↳ interface running on VyOS'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> disable

Disable given `<interface>`. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 disable
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 disable-link-detect
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 mac '00:01:02:03:04:05'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 mtu 9000
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip arp-cache-timeout 180
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip disable-arp-filter
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces pseudo-ethernet peth0 vif 10 ip disable-forwarding
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-accept
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-announce
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-arp-ignore
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ip enable-proxy-arp
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces pseudo-ethernet <interface> vif <vlan-id> ip source-validation  
<strict | loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address autoconf
```

```
set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address eui64  
<prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

```
set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6 address  
no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 address no-default-link-local
```

```
set interfaces pseudo-ethernet <interface> vif <vlan-id> ipv6  
disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 ipv6 disable-forwarding
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 vrf red
```

DHCP(v6)

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options client-id 'foo-bar'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options host-name 'VyOS'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options no-default-route
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options default-route-distance 220
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcp-options reject 192.168.100.0/24
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces pseudo-ethernet peth0 vif 10 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options parameters-only
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options rapid-commit
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd *<id>*. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 length 56
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of *<prefix>::ffff*, as the address 65534 will correspond to *ffff* in hexadecimal notation.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 interface eth8 ↵
↪address 65534
```

set interfaces pseudo-ethernet <interface> vif <vlan-id> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces pseudo-ethernet peth0 vif 10 dhcpv6-options pd 0 interface eth8 ↵
↪sla-id 1
```

8.4.13 Tunnel

This article touches on ‘classic’ IP tunneling protocols.

GRE is often seen as a one size fits all solution when it comes to classic IP tunneling protocols, and for a good reason. However, there are more specialized options, and many of them are supported by VyOS. There are also rather obscure GRE options that can be useful.

All those protocols are grouped under `interfaces tunnel` in VyOS. Let’s take a closer look at the protocols and options currently supported by VyOS.

Common interface configuration

set interfaces tunnel <interface> address <address>

Configure interface *<interface>* with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces tunnel tun0 address 192.0.2.1/24
set interfaces tunnel tun0 address 2001:db8::1/64
```

set interfaces tunnel <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces tunnel tun0 description 'This is an awesome interface running on
↳ VyOS'
```

set interfaces tunnel <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces tunnel tun0 disable
```

set interfaces tunnel <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces tunnel tun0 disable-flow-control
```

set interfaces tunnel <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces tunnel tun0 disable-link-detect
```

set interfaces tunnel <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces tunnel tun0 mac '00:01:02:03:04:05'
```

set interfaces tunnel <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces tunnel tun0 mtu 9000
```

set interfaces tunnel <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces tunnel tun0 ip arp-cache-timeout 180
```

set interfaces tunnel <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces tunnel tun0 ip disable-arp-filter
```

set interfaces tunnel <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces tunnel tun0 ip disable-forwarding
```

set interfaces tunnel <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces tunnel tun0 ip enable-arp-accept
```

set interfaces tunnel <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces tunnel tun0 ip enable-arp-announce
```

set interfaces tunnel <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces tunnel tun0 ip enable-arp-ignore
```

set interfaces tunnel <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces tunnel tun0 ip enable-proxy-arp
```

set interfaces tunnel <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces tunnel <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces tunnel <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces tunnel tun0 ipv6 address autoconf
```

set interfaces tunnel <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces tunnel tun0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces tunnel <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces tunnel tun0 ipv6 address no-default-link-local
```

set interfaces tunnel <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces tunnel tun0 ipv6 disable-forwarding
```

set interfaces tunnel <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces tunnel tun0 vrf red
```

IPIP

This is one of the simplest types of tunnels, as defined by [RFC 2003](#). It takes an IPv4 packet and sends it as a payload of another IPv4 packet. For this reason, there are no other configuration options for this kind of tunnel.

An example:

```
set interfaces tunnel tun0 encapsulation ipip
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 203.0.113.20
set interfaces tunnel tun0 address 192.168.100.200/24
```

IP6IP6

This is the IPv6 counterpart of IPIP. I'm not aware of an RFC that defines this encapsulation specifically, but it's a natural specific case of IPv6 encapsulation mechanisms described in [:rfc:2473](#).

It's not likely that anyone will need it any time soon, but it does exist.

An example:

```
set interfaces tunnel tun0 encapsulation ip6ip6
set interfaces tunnel tun0 source-address 2001:db8:aa::1
set interfaces tunnel tun0 remote 2001:db8:aa::2
set interfaces tunnel tun0 address 2001:db8:bb::1/64
```

IPIP6

In the future this is expected to be a very useful protocol (though there are [other proposals](#)).

As the name implies, it's IPv4 encapsulated in IPv6, as simple as that.

An example:

```
set interfaces tunnel tun0 encapsulation ipip6
set interfaces tunnel tun0 source-address 2001:db8:aa::1
set interfaces tunnel tun0 remote 2001:db8:aa::2
set interfaces tunnel tun0 address 192.168.70.80/24
```

6in4 (SIT)

6in4 uses tunneling to encapsulate IPv6 traffic over IPv4 links as defined in [RFC 4213](#). The 6in4 traffic is sent over IPv4 inside IPv4 packets whose IP headers have the IP protocol number set to 41. This protocol number is specifically designated for IPv6 encapsulation, the IPv4 packet header is immediately followed by the IPv6 packet being carried. The encapsulation overhead is the size of the IPv4 header of 20 bytes, therefore with an MTU of 1500 bytes, IPv6 packets of 1480 bytes can be sent without fragmentation. This tunneling technique is frequently used by IPv6 tunnel brokers like [Hurricane Electric](#).

An example:

```
set interfaces tunnel tun0 encapsulation sit
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 2001:db8:bb::1/64
```

A full example of a Tunnelbroker.net config can be found at [here](#).

Generic Routing Encapsulation (GRE)

A GRE tunnel operates at layer 3 of the OSI model and is represented by IP protocol 47. The main benefit of a GRE tunnel is that you are able to carry multiple protocols inside the same tunnel. GRE also supports multicast traffic and supports routing protocols that leverage multicast to form neighbor adjacencies.

A VyOS GRE tunnel can carry both IPv4 and IPv6 traffic and can also be created over either IPv4 (gre) or IPv6 (ip6gre).

Configuration

A basic configuration requires a tunnel source (source-address), a tunnel destination (remote), an encapsulation type (gre), and an address (ipv4/ipv6). Below is a basic IPv4 only configuration example taken from a VyOS router and a Cisco IOS router. The main difference between these two configurations is that VyOS requires you explicitly configure the encapsulation type. The Cisco router defaults to GRE IP otherwise it would have to be configured as well.

VyOS Router:

```
set interfaces tunnel tun100 address '10.0.0.1/30'
set interfaces tunnel tun100 encapsulation 'gre'
set interfaces tunnel tun100 source-address '198.51.100.2'
set interfaces tunnel tun100 remote '203.0.113.10'
```

Cisco IOS Router:

```
interface Tunnel100
ip address 10.0.0.2 255.255.255.252
tunnel source 203.0.113.10
tunnel destination 198.51.100.2
```

Here is a second example of a dual-stack tunnel over IPv6 between a VyOS router and a Linux host using systemd-networkd.

VyOS Router:

```
set interfaces tunnel tun101 address '2001:db8:feed:beef::1/126'
set interfaces tunnel tun101 address '192.168.5.1/30'
set interfaces tunnel tun101 encapsulation 'ip6gre'
set interfaces tunnel tun101 source-address '2001:db8:babe:face::3afe:3'
set interfaces tunnel tun101 remote '2001:db8:9bb:3ce::5'
```

Linux systemd-networkd:

This requires two files, one to create the device (XXX.netdev) and one to configure the network on the device (XXX.network)

```
# cat /etc/systemd/network/gre-example.netdev
[NetDev]
Name=gre-example
Kind=ip6gre
MTUBytes=14180

[Tunnel]
Remote=2001:db8:babe:face::3afe:3

# cat /etc/systemd/network/gre-example.network
```

(continues on next page)

(continued from previous page)

```
[Match]
Name=gre-example

[Network]
Address=2001:db8:feed:beef::2/126

[Address]
Address=192.168.5.2/30
```

Tunnel keys

GRE is also the only classic protocol that allows creating multiple tunnels with the same source and destination due to its support for tunnel keys. Despite its name, this feature has nothing to do with security: it's simply an identifier that allows routers to tell one tunnel from another.

An example:

```
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 10.40.50.60/24
set interfaces tunnel tun0 parameters ip key 10
```

```
set interfaces tunnel tun0 source-address 192.0.2.10
set interfaces tunnel tun0 remote 192.0.2.20
set interfaces tunnel tun0 address 172.16.17.18/24
set interfaces tunnel tun0 parameters ip key 20
```

GRETAP

While normal GRE is for layer 3, GRETAP is for layer 2. GRETAP can encapsulate Ethernet frames, thus it can be bridged with other interfaces to create datalink layer segments that span multiple remote sites.

```
set interfaces bridge br0 member interface eth0
set interfaces bridge br0 member interface tun0
set interfaces tunnel tun0 encapsulation gretap
set interfaces tunnel tun0 source-address 198.51.100.2
set interfaces tunnel tun0 remote 203.0.113.10
```

Troubleshooting

GRE is a well defined standard that is common in most networks. While not inherently difficult to configure there are a couple of things to keep in mind to make sure the configuration performs as expected. A common cause for GRE tunnels to fail to come up correctly include ACL or Firewall configurations that are discarding IP protocol 47 or blocking your source/destination traffic.

1. Confirm IP connectivity between tunnel source-address and remote:

```
vyos@vyos:~$ ping 203.0.113.10 interface 198.51.100.2 count 4
PING 203.0.113.10 (203.0.113.10) from 198.51.100.2 : 56(84) bytes of data.
64 bytes from 203.0.113.10: icmp_seq=1 ttl=254 time=0.807 ms
64 bytes from 203.0.113.10: icmp_seq=2 ttl=254 time=1.50 ms
```

(continues on next page)

(continued from previous page)

```
64 bytes from 203.0.113.10: icmp_seq=3 ttl=254 time=0.624 ms
64 bytes from 203.0.113.10: icmp_seq=4 ttl=254 time=1.41 ms

--- 203.0.113.10 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3007ms
rtt min/avg/max/mdev = 0.624/1.087/1.509/0.381 ms
```

2. Confirm the link type has been set to GRE:

```
vyos@vyos:~$ show interfaces tunnel tun100
tun100@NONE: <POINTOPOINT,NOARP,UP,LOWER_UP> mtu 1476 qdisc noqueue state UNKNOWN_
↪group default qlen 1000
  link/gre 198.51.100.2 peer 203.0.113.10
  inet 10.0.0.1/30 brd 10.0.0.3 scope global tun100
    valid_lft forever preferred_lft forever
  inet6 fe80::5efe:c612:2/64 scope link
    valid_lft forever preferred_lft forever

RX:  bytes      packets      errors      dropped      overrun      mcast
    2183         27          0           0           0           0
TX:  bytes      packets      errors      dropped      carrier collisions
    836          9          0           0           0           0
```

3. Confirm IP connectivity across the tunnel:

```
vyos@vyos:~$ ping 10.0.0.2 interface 10.0.0.1 count 4
PING 10.0.0.2 (10.0.0.2) from 10.0.0.1 : 56(84) bytes of data.
64 bytes from 10.0.0.2: icmp_seq=1 ttl=255 time=1.05 ms
64 bytes from 10.0.0.2: icmp_seq=2 ttl=255 time=1.88 ms
64 bytes from 10.0.0.2: icmp_seq=3 ttl=255 time=1.98 ms
64 bytes from 10.0.0.2: icmp_seq=4 ttl=255 time=1.98 ms

--- 10.0.0.2 ping statistics ---
4 packets transmitted, 4 received, 0% packet loss, time 3008ms
rtt min/avg/max/mdev = 1.055/1.729/1.989/0.395 ms
```

Note: There is also a GRE over IPv6 encapsulation available, it is called: ip6gre.

8.4.14 VTI - Virtual Tunnel Interface

Set Virtual Tunnel Interface

```
set interfaces vti vti0 address 192.168.2.249/30
set interfaces vti vti0 address 2001:db8:2::249/64
```

Results in:

```
vyos@vyos# show interfaces vti
vti vti0 {
    address 192.168.2.249/30
    address 2001:db8:2::249/64
    description "Description"
}
```

8.4.15 VXLAN

VXLAN is a network virtualization technology that attempts to address the scalability problems associated with large cloud computing deployments. It uses a VLAN-like encapsulation technique to encapsulate OSI layer 2 Ethernet frames within layer 4 UDP datagrams, using 4789 as the default IANA-assigned destination UDP port number. VXLAN endpoints, which terminate VXLAN tunnels and may be either virtual or physical switch ports, are known as VTEPs (VXLAN tunnel endpoints).

VXLAN is an evolution of efforts to standardize an overlay encapsulation protocol. It increases the scalability up to 16 million logical networks and allows for layer 2 adjacency across IP networks. Multicast or unicast with head-end replication (HER) is used to flood broadcast, unknown unicast, and multicast (BUM) traffic.

The VXLAN specification was originally created by VMware, Arista Networks and Cisco. Other backers of the VXLAN technology include Huawei, Broadcom, Citrix, Pica8, Big Switch Networks, Cumulus Networks, Dell EMC, Ericsson, Mellanox, FreeBSD, OpenBSD, Red Hat, Joyent, and Juniper Networks.

VXLAN was officially documented by the IETF in [RFC 7348](#).

If configuring VXLAN in a VyOS virtual machine, ensure that MAC spoofing (Hyper-V) or Forged Transmits (ESX) are permitted, otherwise forwarded frames may be blocked by the hypervisor.

Note: As VyOS is based on Linux and there was no official IANA port assigned for VXLAN, VyOS uses a default port of 8472. You can change the port on a per VXLAN interface basis to get it working across multiple vendors.

Configuration

Common interface configuration

set interfaces vxlan <interface> address <address>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64

Example:

```
set interfaces vxlan vxlan0 address 192.0.2.1/24
set interfaces vxlan vxlan0 address 2001:db8::1/64
```

set interfaces vxlan <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces vxlan vxlan0 description 'This is an awesome interface running on VyOS'
```

set interfaces vxlan <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces vxlan vxlan0 disable
```

set interfaces vxlan <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces vxlan vxlan0 disable-flow-control
```

set interfaces vxlan <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces vxlan vxlan0 disable-link-detect
```

set interfaces vxlan <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces vxlan vxlan0 mac '00:01:02:03:04:05'
```

set interfaces vxlan <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces vxlan vxlan0 mtu 9000
```

set interfaces vxlan <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces vxlan vxlan0 ip arp-cache-timeout 180
```

set interfaces vxlan <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces vxlan vxlan0 ip disable-arp-filter
```

set interfaces vxlan <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces vxlan vxlan0 ip disable-forwarding
```

set interfaces vxlan <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces vxlan vxlan0 ip enable-arp-accept
```

set interfaces vxlan <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces vxlan vxlan0 ip enable-arp-announce
```

set interfaces vxlan <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces vxlan vxlan0 ip enable-arp-ignore
```

set interfaces vxlan <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces vxlan vxlan0 ip enable-proxy-arp
```

set interfaces vxlan <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces vxlan <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces vxlan <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces vxlan vxlan0 ipv6 address autoconf
```

set interfaces vxlan <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces vxlan vxlan0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces vxlan <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces vxlan vxlan0 ipv6 address no-default-link-local
```

set interfaces vxlan <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces vxlan vxlan0 ipv6 disable-forwarding
```

set interfaces vxlan <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces vxlan vxlan0 vrf red
```

VXLAN specific options

set interfaces vxlan <interface> vni <number>

Each VXLAN segment is identified through a 24-bit segment ID, termed the VNI, This allows up to 16M VXLAN segments to coexist within the same administrative domain.

set interfaces vxlan <interface> port <port>

Configure port number of remote VXLAN endpoint.

Note: As VyOS is Linux based the default port used is not using 4789 as the default IANA-assigned destination UDP port number. Instead VyOS uses the Linux default port of 8472.

set interfaces vxlan <interface> source-address <interface>

Source IP address used for VXLAN underlay. This is mandatory when using VXLAN via L2VPN/EVPN.

Unicast

set interfaces vxlan <interface> remote <address>

IPv4/IPv6 remote address of the VXLAN tunnel. Alternative to multicast, the remote IPv4/IPv6 address can set directly.

Multicast

set interfaces vxlan <interface> source-interface <interface>

Interface used for VXLAN underlay. This is mandatory when using VXLAN via a multicast network. VXLAN traffic will always enter and exit this interface.

set interfaces vxlan <interface> group <address>

Multicast group address for VXLAN interface. VXLAN tunnels can be built either via Multicast or via Unicast.

Both IPv4 and IPv6 multicast is possible.

Multicast VXLAN

Topology: PC4 - Leaf2 - Spine1 - Leaf3 - PC5

PC4 has IP 10.0.0.4/24 and PC5 has IP 10.0.0.5/24, so they believe they are in the same broadcast domain.

Let's assume PC4 on Leaf2 wants to ping PC5 on Leaf3. Instead of setting Leaf3 as our remote end manually, Leaf2 encapsulates the packet into a UDP-packet and sends it to its designated multicast-address via Spine1. When Spine1 receives this packet it forwards it to all other leaves who has joined the same multicast-group, in this case Leaf3. When Leaf3 receives the packet it forwards it, while at the same time learning that PC4 is reachable behind Leaf2, because the encapsulated packet had Leaf2's IP address set as source IP.

PC5 receives the ping echo, responds with an echo reply that Leaf3 receives and this time forwards to Leaf2's unicast address directly because it learned the location of PC4 above. When Leaf2 receives the echo reply from PC5 it sees that it came from Leaf3 and so remembers that PC5 is reachable via Leaf3.

Thanks to this discovery, any subsequent traffic between PC4 and PC5 will not be using the multicast-address between the leaves as they both know behind which Leaf the PCs are connected. This saves traffic as less multicast packets sent reduces the load on the network, which improves scalability when more leaves are added.

For optimal scalability, Multicast shouldn't be used at all, but instead use BGP to signal all connected devices between leaves. Unfortunately, VyOS does not yet support this.

Example

The setup is this: Leaf2 - Spine1 - Leaf3

Spine1 is a Cisco IOS router running version 15.4, Leaf2 and Leaf3 is each a VyOS router running 1.2.

This topology was built using GNS3.

Topology:

```
Spine1:
fa0/2 towards Leaf2, IP-address: 10.1.2.1/24
fa0/3 towards Leaf3, IP-address: 10.1.3.1/24

Leaf2:
Eth0 towards Spine1, IP-address: 10.1.2.2/24
Eth1 towards a vlan-aware switch

Leaf3:
Eth0 towards Spine1, IP-address 10.1.3.3/24
Eth1 towards a vlan-aware switch
```

Spine1 Configuration:

```

conf t
ip multicast-routing
!
interface fastethernet0/2
  ip address 10.1.2.1 255.255.255.0
  ip pim sparse-dense-mode
!
interface fastethernet0/3
  ip address 10.1.3.1 255.255.255.0
  ip pim sparse-dense-mode
!
router ospf 1
  network 10.0.0.0 0.255.255.255 area 0

```

Multicast-routing is required for the leaves to forward traffic between each other in a more scalable way. This also requires PIM to be enabled towards the leaves so that the Spine can learn what multicast groups each Leaf expects traffic from.

Leaf2 configuration:

```

set interfaces ethernet eth0 address '10.1.2.2/24'
set protocols ospf area 0 network '10.0.0.0/8'

! Our first vxlan interface
set interfaces bridge br241 address '172.16.241.1/24'
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'

set interfaces vxlan vxlan241 group '239.0.0.241'
set interfaces vxlan vxlan241 source-interface 'eth0'
set interfaces vxlan vxlan241 vni '241'

! Our seconds vxlan interface
set interfaces bridge br242 address '172.16.242.1/24'
set interfaces bridge br242 member interface 'eth1.242'
set interfaces bridge br242 member interface 'vxlan242'

set interfaces vxlan vxlan242 group '239.0.0.242'
set interfaces vxlan vxlan242 source-interface 'eth0'
set interfaces vxlan vxlan242 vni '242'

```

Leaf3 configuration:

```

set interfaces ethernet eth0 address '10.1.3.3/24'
set protocols ospf area 0 network '10.0.0.0/8'

! Our first vxlan interface
set interfaces bridge br241 address '172.16.241.1/24'
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'

set interfaces vxlan vxlan241 group '239.0.0.241'
set interfaces vxlan vxlan241 source-interface 'eth0'
set interfaces vxlan vxlan241 vni '241'

! Our seconds vxlan interface
set interfaces bridge br242 address '172.16.242.1/24'

```

(continues on next page)

(continued from previous page)

```
set interfaces bridge br242 member interface 'eth1.242'
set interfaces bridge br242 member interface 'vxlan242'

set interfaces vxlan vxlan242 group '239.0.0.242'
set interfaces vxlan vxlan242 source-interface 'eth0'
set interfaces vxlan vxlan242 vni '242'
```

As you can see, Leaf2 and Leaf3 configuration is almost identical. There are lots of commands above, I'll try to go into more detail below, command descriptions are placed under the command boxes:

```
set interfaces bridge br241 address '172.16.241.1/24'
```

This command creates a bridge that is used to bind traffic on eth1 vlan 241 with the vxlan241-interface. The IP address is not required. It may however be used as a default gateway for each Leaf which allows devices on the vlan to reach other subnets. This requires that the subnets are redistributed by OSPF so that the Spine will learn how to reach it. To do this you need to change the OSPF network from '10.0.0.0/8' to '0.0.0.0/0' to allow 172.16/12-networks to be advertised.

```
set interfaces bridge br241 member interface 'eth1.241'
set interfaces bridge br241 member interface 'vxlan241'
```

Binds eth1.241 and vxlan241 to each other by making them both member interfaces of the same bridge.

```
set interfaces vxlan vxlan241 group '239.0.0.241'
```

The multicast-group used by all leaves for this vlan extension. Has to be the same on all leaves that has this interface.

```
set interfaces vxlan vxlan241 source-interface 'eth0'
```

Sets the interface to listen for multicast packets on. Could be a loopback, not yet tested.

```
set interfaces vxlan vxlan241 vni '241'
```

Sets the unique id for this vxlan-interface. Not sure how it correlates with multicast-address.

```
set interfaces vxlan vxlan241 port 12345
```

The destination port used for creating a VXLAN interface in Linux defaults to its pre-standard value of 8472 to preserve backward compatibility. A configuration directive to support a user-specified destination port to override that behavior is available using the above command.

Unicast VXLAN

Alternative to multicast, the remote IPv4 address of the VXLAN tunnel can be set directly. Let's change the Multicast example from above:

```
# leaf2 and leaf3
delete interfaces vxlan vxlan241 group '239.0.0.241'
delete interfaces vxlan vxlan241 source-interface 'eth0'

# leaf2
set interface vxlan vxlan241 remote 10.1.3.3

# leaf3
set interface vxlan vxlan241 remote 10.1.2.2
```

The default port udp is set to 8472. It can be changed with `set interface vxlan <vxlanN> port <port>`

8.4.16 WLAN/WIFI - Wireless LAN

WLAN (Wireless LAN) interface provide 802.11 (a/b/g/n/ac) wireless support (commonly referred to as Wi-Fi) by means of compatible hardware. If your hardware supports it, VyOS supports multiple logical wireless interfaces per physical device.

There are three modes of operation for a wireless interface:

- WAP (Wireless Access-Point) provides network access to connecting stations if the physical hardware supports acting as a WAP
- A station acts as a Wi-Fi client accessing the network through an available WAP
- Monitor, the system passively monitors any kind of wireless traffic

If the system detects an unconfigured wireless device, it will be automatically added the configuration tree, specifying any detected settings (for example, its MAC address) and configured to run in monitor mode.

Configuration

Common interface configuration

set interfaces wireless <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces wireless wlan0 address 192.0.2.1/24
set interfaces wireless wlan0 address 2001:db8::1/64
set interfaces wireless wlan0 address dhcp
set interfaces wireless wlan0 address dhcpv6
```

set interfaces wireless <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 description 'This is an awesome interface running
↳ on VyOS'
```

set interfaces wireless <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 disable
```

set interfaces wireless <interface> disable-flow-control

Ethernet flow control is a mechanism for temporarily stopping the transmission of data on Ethernet family computer networks. The goal of this mechanism is to ensure zero packet loss in the presence of network congestion.

The first flow control mechanism, the pause frame, was defined by the IEEE 802.3x standard.

A sending station (computer or network switch) may be transmitting data faster than the other end of the link can accept it. Using flow control, the receiving station can signal the sender requesting suspension of transmissions until the receiver catches up.

Use this command to disable the generation of Ethernet flow control (pause frames).

Example:

```
set interfaces wireless wlan0 disable-flow-control
```

set interfaces wireless <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wireless wlan0 disable-link-detect
```

set interfaces wireless <interface> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 mac '00:01:02:03:04:05'
```

set interfaces wireless <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 mtu 9000
```

set interfaces wireless <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 ip arp-cache-timeout 180
```

set interfaces wireless <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 ip disable-arp-filter
```

set interfaces wireless <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 ip disable-forwarding
```

set interfaces wireless <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 ip enable-arp-accept
```

set interfaces wireless <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 ip enable-arp-announce
```

set interfaces wireless <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 ip enable-arp-ignore
```

set interfaces wireless <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 ip enable-proxy-arp
```

set interfaces wireless <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces wireless <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces wireless <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces wireless wlan0 ipv6 address autoconf
```

set interfaces wireless <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces wireless <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 ipv6 address no-default-link-local
```

set interfaces wireless <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 ipv6 disable-forwarding
```

set interfaces wireless <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vrf red
```

DHCP(v6)

set interfaces wireless <interface> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 dhcp-options client-id 'foo-bar'
```

set interfaces wireless <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 dhcp-options host-name 'VyOS'
```

set interfaces wireless <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces wireless <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 dhcp-options no-default-route
```

set interfaces wireless <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 dhcp-options default-route-distance 220
```

set interfaces wireless <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 dhcp-options reject 192.168.100.0/24
```

set interfaces wireless <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces wireless <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 dhcpv6-options parameters-only
```

set interfaces wireless <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 dhcpv6-options rapid-commit
```

set interfaces wireless <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces wireless <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 dhcpv6-options pd 0 length 56
```

set interfaces wireless <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces wireless <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

Wireless options

set interfaces wireless <interface> channel <number>

Channel number (IEEE 802.11), for 2.4Ghz (802.11 b/g/n) channels range from 1-14. On 5Ghz (802.11 a/h/j/n/ac) channels available are 0, 34 to 173

set interfaces wireless <interface> country-code <cc>

Country code (ISO/IEC 3166-1). Used to set regulatory domain. Set as needed to indicate country in which device is operating. This can limit available channels and transmit power.

Note: This option is mandatory in Access-Point mode.

set interfaces wireless <interface> disable-broadcast-ssid

Send empty SSID in beacons and ignore probe request frames that do not specify full SSID, i.e., require stations to know SSID.

set interfaces wireless <interface> expunge-failing-stations

Disassociate stations based on excessive transmission failures or other indications of connection loss.

This depends on the driver capabilities and may not be available with all drivers.

```
set interfaces wireless <interface> isolate-stations
```

Client isolation can be used to prevent low-level bridging of frames between associated stations in the BSS.

By default, this bridging is allowed.

```
set interfaces wireless <interface> max-stations
```

Maximum number of stations allowed in station table. New stations will be rejected after the station table is full. IEEE 802.11 has a limit of 2007 different association IDs, so this number should not be larger than that.

This defaults to 2007.

```
set interfaces wireless <interface> mgmt-frame-protection
```

Management Frame Protection (MFP) according to IEEE 802.11w

```
set interfaces wireless <interface> mode <a | b | g | n | ac>
```

Operation mode of wireless radio.

- a - 802.11a - 54 Mb/s/sec
- b - 802.11b - 11 Mb/s/sec
- g - 802.11g - 54 Mb/s/sec (default)
- n - 802.11n - 600 Mb/s/sec
- ac - 802.11ac - 1300 Mb/s/sec

```
set interfaces wireless <interface> physical-device <device>
```

Wireless hardware device used as underlay radio.

This defaults to phy0.

```
set interfaces wireless <interface> reduce-transmit-power <number>
```

Add Power Constraint element to Beacon and Probe Response frames.

This option adds Power Constraint element when applicable and Country element is added. Power Constraint element is required by Transmit Power Control.

Valid values are 0..255.

```
set interfaces wireless <interface> ssid <ssid>
```

SSID to be used in IEEE 802.11 management frames

```
set interfaces wireless <interface> type <access-point | station | monitor>
```

Wireless device type for this interface

- access-point - Access-point forwards packets between other nodes
- station - Connects to another access point
- monitor - Passively monitor all packets on the frequency/channel

PPDU

```
set interfaces wireless <interface> capabilities require-ht
```

```
set interfaces wireless <interface> capabilities require-hvt
```

HT (High Throughput) capabilities (802.11n)

```
set interfaces wireless <interface> capabilities ht 40mhz-incapable
```

Device is incapable of 40 MHz, do not advertise. This sets [40-INTOLERANT]

```
set interfaces wireless <interface> capabilities ht auto-powersave
```

WMM-PS Unscheduled Automatic Power Save Delivery [U-APSD]

```
set interfaces wireless <interface> capabilities ht channel-set-width <ht20 | ht40+ | ht40->
```

Supported channel width set.

- ht40- - Both 20 MHz and 40 MHz with secondary channel below the primary channel
- ht40+ - Both 20 MHz and 40 MHz with secondary channel above the primary channel

Note: There are limits on which channels can be used with HT40- and HT40+. Following table shows the channels that may be available for HT40- and HT40+ use per IEEE 802.11n Annex J:

Depending on the location, not all of these channels may be available for use!

freq	HT40-	HT40+
2.4 GHz	5-13	1-7 (1-9 in Europe/Japan)
5 GHz	40, 48, 56, 64	36, 44, 52, 60

Note: 40 MHz channels may switch their primary and secondary channels if needed or creation of 40 MHz channel maybe rejected based on overlapping BSSes. These changes are done automatically when hostapd is setting up the 40 MHz channel.

```
set interfaces wireless <interface> capabilities ht delayed-block-ack
```

Enable HT-delayed Block Ack [DELAYED-BA]

```
set interfaces wireless <interface> capabilities ht dsss-cck-40
```

DSSS/CCK Mode in 40 MHz, this sets [DSSS_CCK-40]

```
set interfaces wireless <interface> capabilities ht greenfield
```

This enables the greenfield option which sets the [GF] option

```
set interfaces wireless <interface> capabilities ht ldpc
```

Enable LDPC coding capability

```
set interfaces wireless <interface> capabilities ht lsig-protection
```

Enable L-SIG TXOP protection capability

```
set interfaces wireless <interface> capabilities ht max-amsdu <3839 | 7935>
```

Maximum A-MSDU length 3839 (default) or 7935 octets

```
set interfaces wireless <interface> capabilities ht short-gi <20 | 40>
```

Short GI capabilities for 20 and 40 MHz

```
set interfaces wireless <interface> capabilities ht smps <static | dynamic>
```

Spatial Multiplexing Power Save (SMPS) settings

```
set interfaces wireless <interface> capabilities ht stbc rx <num>
```

Enable receiving PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities ht stbc tx
```

Enable sending PPDU using STBC (Space Time Block Coding)

VHT (Very High Throughput) capabilities (802.11ac)

```
set interfaces wireless <interface> capabilities vht antenna-count
```

Number of antennas on this card

```
set interfaces wireless <interface> capabilities vht antenna-pattern-fixed
```

Set if antenna pattern does not change during the lifetime of an association

```
set interfaces wireless <interface> capabilities vht beamform  
<single-user-beamformer | single-user-beamformee | multi-user-beamformer |  
multi-user-beamformee>
```

Beamforming capabilities:

- single-user-beamformer - Support for operation as single user beamformer
- single-user-beamformee - Support for operation as single user beamformee
- multi-user-beamformer - Support for operation as single user beamformer
- multi-user-beamformee - Support for operation as single user beamformer

```
set interfaces wireless <interface> capabilities vht center-channel-freq  
<freq-1 | freq-2> <number>
```

VHT operating channel center frequency - center freq 1 (for use with 80, 80+80 and 160 modes)

VHT operating channel center frequency - center freq 2 (for use with the 80+80 mode)

<number> must be from 34 - 173. For 80 MHz channels it should be channel + 6.

```
set interfaces wireless <interface> capabilities vht channel-set-width <0 | 1  
| 2 | 3>
```

- 0 - 20 or 40 MHz channel width (default)
- 1 - 80 MHz channel width
- 2 - 160 MHz channel width
- 3 - 80+80 MHz channel width

```
set interfaces wireless <interface> capabilities vht ldpc
```

Enable LDPC (Low Density Parity Check) coding capability

```
set interfaces wireless <interface> capabilities vht link-adaptation
```

VHT link adaptation capabilities

```
set interfaces wireless <interface> capabilities vht max-mpdu <value>
```

Increase Maximum MPDU length to 7991 or 11454 octets (default 3895 octets)

```
set interfaces wireless <interface> capabilities vht max-mpdu-exp <value>
```

Set the maximum length of A-MPDU pre-EOF padding that the station can receive

```
set interfaces wireless <interface> capabilities vht short-gi <80 | 160>
```

Short GI capabilities

```
set interfaces wireless <interface> capabilities vht stbc rx <num>
```

Enable receiving PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities vht stbc tx
```

Enable sending PPDU using STBC (Space Time Block Coding)

```
set interfaces wireless <interface> capabilities vht tx-powersave
```

Enable VHT TXOP Power Save Mode

```
set interfaces wireless <interface> capabilities vht vht-cf
```

Station supports receiving VHT variant HT Control field

Wireless options (Station/Client)

The example creates a wireless station (commonly referred to as Wi-Fi client) that accesses the network through the WAP defined in the above example. The default physical device (phy0) is used.

```
set interfaces wireless wlan0 type station
set interfaces wireless wlan0 address dhcp
set interfaces wireless wlan0 ssid Test
set interfaces wireless wlan0 security wpa
```

Resulting in

```
interfaces {
  [...]
  wireless wlan0 {
    address dhcp
    security {
      wpa {
        passphrase "12345678"
      }
    }
    ssid TEST
    type station
  }
}
```

Security

WPA (Wi-Fi Protected Access) and WPA2 Enterprise in combination with 802.1x based authentication can be used to authenticate users or computers in a domain.

The wireless client (supplicant) authenticates against the RADIUS server (authentication server) using an EAP method configured on the RADIUS server. The WAP (also referred to as authenticator) role is to send all authentication messages between the supplicant and the configured authentication server, thus the RADIUS server is responsible for authenticating the users.

The WAP in this example has the following characteristics:

- IP address 192.168.2.1/24

- Network ID (SSID) Enterprise-TEST
- WPA passphrase 12345678
- Use 802.11n protocol
- Wireless channel 1
- RADIUS server at 192.168.3.10 with shared-secret VyOSPassword

```
set interfaces wireless wlan0 address '192.168.2.1/24'
set interfaces wireless wlan0 type access-point
set interfaces wireless wlan0 channel 1
set interfaces wireless wlan0 mode n
set interfaces wireless wlan0 ssid 'TEST'
set interfaces wireless wlan0 security wpa mode wpa2
set interfaces wireless wlan0 security wpa cipher CCMP
set interfaces wireless wlan0 security wpa radius server 192.168.3.10 key
↪ 'VyOSPassword'
set interfaces wireless wlan0 security wpa radius server 192.168.3.10 port 1812
```

Resulting in

```
interfaces {
  [...]
  wireless wlan0 {
    address 192.168.2.1/24
    channel 1
    mode n
    security {
      wpa {
        cipher CCMP
        mode wpa2
        radius {
          server 192.168.3.10 {
            key 'VyOSPassword'
            port 1812
          }
        }
      }
    }
    ssid "Enterprise-TEST"
    type access-point
  }
}
system {
  [...]
  wifi-regulatory-domain DE
}
```

VLAN

Regular VLANs (802.1q)

IEEE 802.1q, often referred to as Dot1q, is the networking standard that supports virtual LANs (VLANs) on an IEEE 802.3 Ethernet network. The standard defines a system of VLAN tagging for Ethernet frames and the accompanying procedures to be used by bridges and switches in handling such frames. The standard also contains provisions

for a quality-of-service prioritization scheme commonly known as IEEE 802.1p and defines the Generic Attribute Registration Protocol.

Portions of the network which are VLAN-aware (i.e., IEEE 802.1q conformant) can include VLAN tags. When a frame enters the VLAN-aware portion of the network, a tag is added to represent the VLAN membership. Each frame must be distinguishable as being within exactly one VLAN. A frame in the VLAN-aware portion of the network that does not contain a VLAN tag is assumed to be flowing on the native VLAN.

The standard was developed by IEEE 802.1, a working group of the IEEE 802 standards committee, and continues to be actively revised. One of the notable revisions is 802.1Q-2014 which incorporated IEEE 802.1aq (Shortest Path Bridging) and much of the IEEE 802.1d standard.

802.1q VLAN interfaces are represented as virtual sub-interfaces in VyOS. The term used for this is `vif`.

set interfaces wireless <interface> vif <vlan-id>

Create a new VLAN interface on interface `<interface>` using the VLAN number provided via `<vlan-id>`.

You can create multiple VLAN interfaces on a physical interface. The VLAN ID range is from 0 to 4094.

Note: Only 802.1Q-tagged packets are accepted on Ethernet vifs.

set interfaces wireless <interface> vif <vlan-id> address <address | dhcp | dhcpv6>

Configure interface `<interface>` with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces wireless wlan0 vif 10 address 192.0.2.1/24
set interfaces wireless wlan0 vif 10 address 2001:db8::1/64
set interfaces wireless wlan0 vif 10 address dhcp
set interfaces wireless wlan0 vif 10 address dhcpv6
```

set interfaces wireless <interface> vif <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 vif 10 description 'This is an awesome interface_
↳running on VyOS'
```

set interfaces wireless <interface> vif <vlan-id> disable

Disable given `<interface>`. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 vif 10 disable
```

set interfaces wireless <interface> vif <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces wireless wlan0 vif 10 disable-link-detect
```

set interfaces wireless <interface> vif <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 vif 10 mac '00:01:02:03:04:05'
```

set interfaces wireless <interface> vif <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 vif 10 mtu 9000
```

set interfaces wireless <interface> vif <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 vif 10 ip arp-cache-timeout 180
```

set interfaces wireless <interface> vif <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 vif 10 ip disable-arp-filter
```

set interfaces wireless <interface> vif <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 vif 10 ip disable-forwarding
```

set interfaces wireless <interface> vif <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-accept
```

set interfaces wireless <interface> vif <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-announce
```

set interfaces wireless <interface> vif <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 vif 10 ip enable-arp-ignore
```

set interfaces wireless <interface> vif <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 vif 10 ip enable-proxy-arp
```

set interfaces wireless <interface> vif <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation

- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

```
set interfaces wireless <interface> vif <vlan-id> ip source-validation <strict  
| loose | disable>
```

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

```
set interfaces wireless <interface> vif <vlan-id> ipv6 address autoconf
```

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address autoconf
```

```
set interfaces wireless <interface> vif <vlan-id> ipv6 address eui64 <prefix>
```

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address eui64 2001:db8:beef::/64
```

```
set interfaces wireless <interface> vif <vlan-id> ipv6 address  
no-default-link-local
```

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 address no-default-link-local
```

```
set interfaces wireless <interface> vif <vlan-id> ipv6 disable-forwarding
```

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 vif 10 ipv6 disable-forwarding
```

```
set interfaces wireless <interface> vif <vlan-id> vrf <vrf>
```

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vif 10 vrf red
```

DHCP(v6)

set interfaces wireless <interface> vif <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options client-id 'foo-bar'
```

set interfaces wireless <interface> vif <vlan-id> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options host-name 'VyOS'
```

set interfaces wireless <interface> vif <vlan-id> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options vendor-class-id 'VyOS'
```

set interfaces wireless <interface> vif <vlan-id> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options no-default-route
```

set interfaces wireless <interface> vif <vlan-id> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 vif 10 dhcp-options default-route-distance 220
```

set interfaces wireless <interface> vif <vlan-id> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 vif 10 dhcpv6-options reject 192.168.100.0/24
```

set interfaces wireless <interface> vif <vlan-id> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 vif 10 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces wireless <interface> vif <vlan-id> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options parameters-only
```

set interfaces wireless <interface> vif <vlan-id> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options rapid-commit
```

set interfaces wireless <interface> vif <vlan-id> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 length 56
```

```
set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id>  
interface <delegatee> address <address>
```

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 interface eth8 address_
→65534
```

```
set interfaces wireless <interface> vif <vlan-id> dhcpv6-options pd <id>  
interface <delegatee> sla-id <id>
```

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 vif 10 dhcpv6-options pd 0 interface eth8 sla-id 1
```

QinQ (802.1ad)

IEEE 802.1ad was an Ethernet networking standard informally known as QinQ as an amendment to IEEE standard 802.1q VLAN interfaces as described above. 802.1ad was incorporated into the base 802.1q standard in 2011. The technique is also known as provider bridging, Stacked VLANs, or simply QinQ or Q-in-Q. “Q-in-Q” can for supported devices apply to C-tag stacking on C-tag (Ethernet Type = 0x8100).

The original 802.1q specification allows a single Virtual Local Area Network (VLAN) header to be inserted into an Ethernet frame. QinQ allows multiple VLAN tags to be inserted into a single frame, an essential capability for implementing Metro Ethernet network topologies. Just as QinQ extends 802.1Q, QinQ itself is extended by other Metro Ethernet protocols.

In a multiple VLAN header context, out of convenience the term “VLAN tag” or just “tag” for short is often used in place of “802.1q VLAN header”. QinQ allows multiple VLAN tags in an Ethernet frame; together these tags constitute a tag stack. When used in the context of an Ethernet frame, a QinQ frame is a frame that has 2 VLAN 802.1q headers (double-tagged).

In VyOS the terms `vif-s` and `vif-c` stand for the ethertype tags that are used.

The inner tag is the tag which is closest to the payload portion of the frame. It is officially called C-TAG (customer tag, with ethertype 0x8100). The outer tag is the one closer/closest to the Ethernet header, its name is S-TAG (service tag with Ethernet Type = 0x88a8).

```
set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> address  
<address | dhcp | dhcpv6>
```

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address 192.0.2.1/24
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address 2001:db8::1/64
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address dhcp
set interfaces wireless wlan0 vif-s 1000 vif-c 20 address dhcpv6
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 description 'This is an_
→awesome interface running on VyOS'
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 disable
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detects physical link state changes.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 disable-link-detect
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> mac <xx:xx:xx:xx:xx:xx>

Configure user defined MAC address on given <interface>.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 mac '00:01:02:03:04:05'
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 mtu 9000
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip arp-cache-timeout 180
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip disable-arp-filter
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip disable-forwarding
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-accept
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-announce
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-arp-ignore
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ip enable-proxy-arp
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address autoconf
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address eui64 ↵
↪2001:db8:beef::/64
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 address no-default-link-
↪local
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 ipv6 disable-forwarding
```

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 vrf red
```

DHCP(v6)

set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the ‘client identifier’ option. If the client supplies a ‘client identifier’, the client MUST use the same ‘client identifier’ in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options client-id 'foo-bar
→ '
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options host-name <hostname>**

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options host-name 'VyOS'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options vendor-class-id <vendor-id>**

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options vendor-class-id
→ 'VyOS'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options no-default-route**

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options no-default-route
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options default-route-distance <distance>**

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options default-route-
→ distance 220
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcp-options reject <address>**

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcp-options reject 192.168.
→ 100.0/24
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options duid <duid>**

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 duid
→ '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options parameters-only**

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options parameters-only
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options rapid-commit**

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options rapid-commit
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options temporary**

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> length <length>**

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 length 56
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> address <address>**

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
→eth8 address 65534
```

**set interfaces wireless <interface> vif-s <vlan-id> vif-c <vlan-id>
dhcpv6-options pd <id> interface <delegatee> sla-id <id>**

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wireless wlan0 vif-s 1000 vif-c 20 dhcpv6-options pd 0 interface_
→eth8 sla-id 1
```

Operation

show interfaces wireless info

Use this command to view operational status and wireless-specific information about all wireless interfaces.

```
vyos@vyos:~$ show interfaces wireless info
Interface  Type          SSID              Channel
wlan0      access-point  VyOS-TEST-0      1
```

show interfaces wireless detail

Use this command to view operational status and details wireless-specific information about all wireless interfaces.

```
vyos@vyos:~$ show interfaces wireless detail
wlan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group_
→default qlen 1000
    link/ether XX:XX:XX:XX:XX:c3 brd XX:XX:XX:XX:XX:ff
    inet xxx.xxx.99.254/24 scope global wlan0

```

show interfaces wireless <wlanX>

This command shows both status and statistics on the specified wireless interface. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0
wlan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc noqueue state UP group_
↪default qlen 1000
    link/ether XX:XX:XX:XX:XX:c3 brd XX:XX:XX:XX:XX:ff
    inet xxx.xxx.99.254/24 scope global wlan0
        valid_lft forever preferred_lft forever
    inet6 fe80::xxxx:xxxx:fe54:2fc3/64 scope link
        valid_lft forever preferred_lft forever

RX:  bytes      packets      errors      dropped      overrun      mcast
    66072         282           0           0           0           0
TX:  bytes      packets      errors      dropped      carrier collisions
    83413         430           0           0           0           0
```

show interfaces wireless <wlanX> brief

This command gives a brief status overview of a specified wireless interface. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0 brief
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
wlan0          192.168.2.254/24  u/u
```

show interfaces wireless <wlanX> queue

Use this command to view wireless interface queue information. The wireless interface identifier can range from wlan0 to wlan999.

```
vyos@vyos:~$ show interfaces wireless wlan0 queue
qdisc pfifo_fast 0: root bands 3 priomap 1 2 2 2 1 2 0 0 1 1 1 1 1 1 1
Sent 810323 bytes 6016 pkt (dropped 0, overlimits 0 requeues 0)
rate 0bit 0pps backlog 0b 0p requeues 0
```

show interfaces wireless <wlanX> scan

This command is used to retrieve information about WAP within the range of your wireless interface. This command is useful on wireless interfaces configured in station mode.

Note: Scanning is not supported on all wireless drivers and wireless hardware. Refer to your driver and wireless hardware documentation for further details.

```
vyos@vyos:~$ show interfaces wireless wlan0 scan
Address      SSID      Channel  Signal (dbm)
00:53:3b:88:6e:d8  WLAN-576405      1      -64.00

00:53:44:46:d2:0b	Vodafone Hotspot	1	-87.00

Examples

The following example creates a WAP. When configuring multiple WAP interfaces, you must specify unique IP addresses, channels, Network IDs commonly referred to as SSID (Service Set Identifier), and MAC addresses.

The WAP in this example has the following characteristics:

- IP address 192.168.2.1/24
- Network ID (SSID) TEST
- WPA passphrase 12345678
- Use 802.11n protocol
- Wireless channel 1

```
set interfaces wireless wlan0 address '192.168.2.1/24'
set interfaces wireless wlan0 type access-point
set interfaces wireless wlan0 channel 1
set interfaces wireless wlan0 mode n
set interfaces wireless wlan0 ssid 'TEST'
set interfaces wireless wlan0 security wpa mode wpa2
set interfaces wireless wlan0 security wpa cipher CCMP
set interfaces wireless wlan0 security wpa passphrase '12345678'
```

Resulting in

```
interfaces {
  [...]
  wireless wlan0 {
    address 192.168.2.1/24
    channel 1
    mode n
    security {
      wpa {
        cipher CCMP
        mode wpa2
        passphrase "12345678"
      }
    }
    ssid "TEST"
    type access-point
  }
}
system {
  [...]
  wifi-regulatory-domain DE
}
```

To get it to work as an access point with this configuration you will need to set up a DHCP server to work with that network. You can - of course - also bridge the Wireless interface with any configured bridge (*Bridge*) on the system.

8.4.17 WWAN - Wireless Wide-Area-Network

The Wireless Wide-Area-Network interface provides access (through a wireless modem/wwan) to wireless networks provided by various cellular providers.

VyOS uses the *interfaces wwan* subsystem for configuration.

Configuration

Common interface configuration

set interfaces wwan <interface> address <address | dhcp | dhcpv6>

Configure interface <interface> with one or more interface addresses.

- **address** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
- **dhcp** interface address is received by DHCP from a DHCP server on this segment.
- **dhcpv6** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
set interfaces wwan wwan0 address 192.0.2.1/24
set interfaces wwan wwan0 address 2001:db8::1/64
set interfaces wwan wwan0 address dhcp
set interfaces wwan wwan0 address dhcpv6
```

set interfaces wwan <interface> description <description>

Set a human readable, descriptive alias for this connection. Alias is used by e.g. the `show interfaces` command or SNMP based monitoring tools.

Example:

```
set interfaces wwan wwan0 description 'This is an awesome interface running on
↳VyOS'
```

set interfaces wwan <interface> disable

Disable given <interface>. It will be placed in administratively down (A/D) state.

Example:

```
set interfaces wwan wwan0 disable
```

set interfaces wwan <interface> disable-link-detect

Use this command to direct an interface to not detect any physical state changes on a link, for example, when the cable is unplugged.

Default is to detect physical link state changes.

Example:

```
set interfaces wwan wwan0 disable-link-detect
```

set interfaces wwan <interface> mtu <mtu>

Configure MTU on given <interface>. It is the size (in bytes) of the largest ethernet frame sent on this link.

Example:

```
set interfaces wwan wwan0 mtu 9000
```

set interfaces wwan <interface> ip arp-cache-timeout

Once a neighbor has been found, the entry is considered to be valid for at least for this specific time. An entry's validity will be extended if it receives positive feedback from higher level protocols.

This defaults to 30 seconds.

Example:

```
set interfaces wwan wwan0 ip arp-cache-timeout 180
```

set interfaces wwan <interface> ip disable-arp-filter

If set the kernel can respond to arp requests with addresses from other interfaces. This may seem wrong but it usually makes sense, because it increases the chance of successful communication. IP addresses are owned by the complete host on Linux, not by particular interfaces. Only for more complex setups like load-balancing, does this behaviour cause problems.

If not set (default) allows you to have multiple network interfaces on the same subnet, and have the ARPs for each interface be answered based on whether or not the kernel would route a packet from the ARP'd IP out that interface (therefore you must use source based routing for this to work).

In other words it allows control of which cards (usually 1) will respond to an arp request.

Example:

```
set interfaces wwan wwan0 ip disable-arp-filter
```

set interfaces wwan <interface> ip disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

```
set interfaces wwan wwan0 ip disable-forwarding
```

set interfaces wwan <interface> ip enable-arp-accept

Define behavior for gratuitous ARP frames who's IP is not already present in the ARP table. If configured create new entries in the ARP table.

Both replies and requests type gratuitous arp will trigger the ARP table to be updated, if this setting is on.

If the ARP table already contains the IP address of the gratuitous arp frame, the arp table will be updated regardless if this setting is on or off.

```
set interfaces wwan wwan0 ip enable-arp-accept
```

set interfaces wwan <interface> ip enable-arp-announce

Define different restriction levels for announcing the local source IP address from IP packets in ARP requests sent on interface.

Use any local address, configured on any interface if this is not set.

If configured, try to avoid local addresses that are not in the target's subnet for this interface. This mode is useful when target hosts reachable via this interface require the source IP address in ARP requests to be part of their logical network configured on the receiving interface. When we generate the request we will check all our subnets that include the target IP and will preserve the source address if it is from such subnet. If there is no such subnet we select source address according to the rules for level 2.

```
set interfaces wwan wwan0 ip enable-arp-announce
```

set interfaces wwan <interface> ip enable-arp-ignore

Define different modes for sending replies in response to received ARP requests that resolve local target IP addresses:

If configured, reply only if the target IP address is local address configured on the incoming interface.

If this option is unset (default), reply for any local target IP address, configured on any interface.

```
set interfaces wwan wwan0 ip enable-arp-ignore
```

set interfaces wwan <interface> ip enable-proxy-arp

Use this command to enable proxy Address Resolution Protocol (ARP) on this interface. Proxy ARP allows an Ethernet interface to respond with its own MAC address to ARP requests for destination IP addresses on subnets attached to other interfaces on the system. Subsequent packets sent to those destination IP addresses are forwarded appropriately by the system.

Example:

```
set interfaces wwan wwan0 ip enable-proxy-arp
```

set interfaces wwan <interface> ip proxy-arp-pvlan

Private VLAN proxy arp. Basically allow proxy arp replies back to the same interface (from which the ARP request/solicitation was received).

This is done to support (ethernet) switch features, like [RFC 3069](#), where the individual ports are NOT allowed to communicate with each other, but they are allowed to talk to the upstream router. As described in [RFC 3069](#), it is possible to allow these hosts to communicate through the upstream router by proxy_arp'ing.

Note: Does not need to be used together with proxy_arp.

This technology is known by different names:

- In [RFC 3069](#) it is called VLAN Aggregation
- Cisco and Allied Telesyn call it Private VLAN
- Hewlett-Packard call it Source-Port filtering or port-isolation
- Ericsson call it MAC-Forced Forwarding (RFC Draft)

set interfaces wwan <interface> ip source-validation <strict | loose | disable>

Enable policy for source validation by reversed path, as specified in [RFC 3704](#). Current recommended practice in [RFC 3704](#) is to enable strict mode to prevent IP spoofing from DDos attacks. If using asymmetric routing or other complicated routing, then loose mode is recommended.

- strict: Each incoming packet is tested against the FIB and if the interface is not the best reverse path the packet check will fail. By default failed packets are discarded.
- loose: Each incoming packet's source address is also tested against the FIB and if the source address is not reachable via any interface the packet check will fail.
- disable: No source validation

set interfaces wwan <interface> ipv6 address autoconf

SLAAC [RFC 4862](#). IPv6 hosts can configure themselves automatically when connected to an IPv6 network using the Neighbor Discovery Protocol via ICMPv6 router discovery messages. When first connected to a network, a host sends a link-local router solicitation multicast request for its configuration parameters; routers respond to such a request with a router advertisement packet that contains Internet Layer configuration parameters.

Note: This method automatically disables IPv6 traffic forwarding on the interface in question.

Example:

```
set interfaces wwan wwan0 ipv6 address autoconf
```

set interfaces wwan <interface> ipv6 address eui64 <prefix>

EUI-64 as specified in [RFC 4291](#) allows a host to assign itself a unique 64-Bit IPv6 address.

Example:

```
set interfaces wwan wwan0 ipv6 address eui64 2001:db8:beef::/64
```

set interfaces wwan <interface> ipv6 address no-default-link-local

Do not assign a link-local IPv6 address to this interface.

Example:

```
set interfaces wwan wwan0 ipv6 address no-default-link-local
```

set interfaces wwan <interface> ipv6 disable-forwarding

Configure interface-specific Host/Router behaviour. If set, the interface will switch to host mode and IPv6 forwarding will be disabled on this interface.

Example:

```
set interfaces wwan wwan0 ipv6 disable-forwarding
```

set interfaces wwan <interface> vrf <vrf>

Place interface in given VRF instance.

See also:

There is an entire chapter about how to configure a [VRF](#), please check this for additional information.

Example:

```
set interfaces wwan wwan0 vrf red
```

DHCP(v6)

set interfaces wwan <interface> dhcp-options client-id <description>

RFC 2131 states: The client MAY choose to explicitly provide the identifier through the 'client identifier' option. If the client supplies a 'client identifier', the client MUST use the same 'client identifier' in all subsequent messages, and the server MUST use that identifier to identify the client.

Example:

```
set interfaces wwan wwan0 dhcp-options client-id 'foo-bar'
```

set interfaces wwan <interface> dhcp-options host-name <hostname>

Instead of sending the real system hostname to the DHCP server, overwrite the host-name with this given-value.

Example:

```
set interfaces wwan wwan0 dhcp-options host-name 'VyOS'
```

set interfaces wwan <interface> dhcp-options vendor-class-id <vendor-id>

The vendor-class-id option can be used to request a specific class of vendor options from the server.

Example:

```
set interfaces wwan wwan0 dhcp-options vendor-class-id 'VyOS'
```

set interfaces wwan <interface> dhcp-options no-default-route

Only request an address from the DHCP server but do not request a default gateway.

Example:

```
set interfaces wwan wwan0 dhcp-options no-default-route
```

set interfaces wwan <interface> dhcp-options default-route-distance <distance>

Set the distance for the default gateway sent by the DHCP server.

Example:

```
set interfaces wwan wwan0 dhcp-options default-route-distance 220
```

set interfaces wwan <interface> dhcp-options reject <address>

Reject DHCP leases from a given address or range. This is useful when a modem gives a local IP when first starting.

- **address** can be specified multiple times, e.g. 192.168.100.1 and/or 192.168.100.0/24

Example:

```
set interfaces wwan wwan0 dhcp-options reject 192.168.100.0/24
```

set interfaces wwan <interface> dhcpv6-options duid <duid>

The DHCP unique identifier (DUID) is used by a client to get an IP address from a DHCPv6 server. It has a 2-byte DUID type field, and a variable-length identifier field up to 128 bytes. Its actual length depends on its type. The server compares the DUID with its database and delivers configuration data (address, lease times, DNS servers, etc.) to the client.

```
set interfaces wwan wwan0 duid '0e:00:00:01:00:01:27:71:db:f0:00:50:56:bf:c5:6d'
```

set interfaces wwan <interface> dhcpv6-options parameters-only

This statement specifies dhcp6c to only exchange informational configuration parameters with servers. A list of DNS server addresses is an example of such parameters. This statement is useful when the client does not need stateful configuration parameters such as IPv6 addresses or prefixes.

```
set interfaces wwan wwan0 dhcpv6-options parameters-only
```

set interfaces wwan <interface> dhcpv6-options rapid-commit

When rapid-commit is specified, dhcp6c will include a rapid-commit option in solicit messages and wait for an immediate reply instead of advertisements.

```
set interfaces wwan wwan0 dhcpv6-options rapid-commit
```

set interfaces wwan <interface> dhcpv6-options temporary

Request only a temporary address and not form an IA_NA (Identity Association for Non-temporary Addresses) partnership.

```
set interfaces wwan wwan0 dhcpv6-options temporary
```

DHCPv6 Prefix Delegation (PD)

VyOS 1.3 (equuleus) supports DHCPv6-PD ([RFC 3633](#)). DHCPv6 Prefix Delegation is supported by most ISPs who provide native IPv6 for consumers on fixed networks.

set interfaces wwan <interface> dhcpv6-options pd <id> length <length>

Some ISPs by default only delegate a /64 prefix. To request for a specific prefix size use this option to request for a bigger delegation for this pd <id>. This value is in the range from 32 - 64 so you could request up to a /32 prefix (if your ISP allows this) down to a /64 delegation.

The default value corresponds to 64.

To request a /56 prefix from your ISP use:

```
set interfaces wwan wwan0 dhcpv6-options pd 0 length 56
```

set interfaces wwan <interface> dhcpv6-options pd <id> interface <delegatee> address <address>

Specify the interface address used locally on the interface where the prefix has been delegated to. ID must be a decimal integer.

It will be combined with the delegated prefix and the sla-id to form a complete interface address. The default is to use the EUI-64 address of the interface.

Example: Delegate a /64 prefix to interface eth8 which will use a local address on this router of <prefix>::ffff, as the address 65534 will correspond to ffff in hexadecimal notation.

```
set interfaces wwan wwan0 dhcpv6-options pd 0 interface eth8 address 65534
```

set interfaces wwan <interface> dhcpv6-options pd <id> interface <delegatee> sla-id <id>

Specify the identifier value of the site-level aggregator (SLA) on the interface. ID must be a decimal number greater than 0 which fits in the length of SLA IDs (see below).

Example: If ID is 1 and the client is delegated an IPv6 prefix 2001:db8:ffff::/48, dhcp6c will combine the two values into a single IPv6 prefix, 2001:db8:ffff:1::/64, and will configure the prefix on the specified interface.

```
set interfaces wwan wwan0 dhcpv6-options pd 0 interface eth8 sla-id 1
```

WirelessModem (WWAN) options

set interfaces wwan <interface> apn <apn>

Every WWAN connection requires an APN (Access Point Name) which is used by the client to dial into the ISPs network. This is a mandatory parameter. Contact your Service Provider for correct APN.

Operation

show interfaces wwan <interface>

Example

The following example is based on a Sierra Wireless MC7710 miniPCIe card (only the form factor in reality it runs USB) and Deutsche Telekom as ISP. The card is assembled into a *PC Engines APU4*.

```
set interfaces wwan wwan0 apn 'internet.telekom'
set interfaces wwan wwan0 address 'dhcp'
```

Supported Modules

The following hardware modules have been tested successfully in an *PC Engines APU4* board:

- Sierra Wireless AirPrime MC7304 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7430 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7455 miniPCIe card (LTE)
- Sierra Wireless AirPrime MC7710 miniPCIe card (LTE)
- Huawei ME909u-521 miniPCIe card (LTE)
- Huawei ME909s-120 miniPCIe card (LTE)

Firmware Update

All available WWAN cards have a build in, reprogrammable firmware. Most of the vendors provide a regular update to the firmware used in the baseband chip.

As VyOS makes use of the QMI interface to connect to the WWAN modem cards, also the firmware can be reprogrammed.

To update the firmware, VyOS also ships the *qmi-firmware-update* binary. To upgrade the firmware of an e.g. Sierra Wireless MC7710 module to the firmware provided in the file 9999999_9999999_9200_03.05.14.00_00_generic_000.000_001_SPKG_MC.cwe use the following command:

```
$ sudo qmi-firmware-update --update -d 1199:68a2 \
  9999999_9999999_9200_03.05.14.00_00_generic_000.000_001_SPKG_MC.cwe
```

8.5 WAN load balancing

Outbound traffic can be balanced between two or more outbound interfaces. If a path fails, traffic is balanced across the remaining healthy paths, a recovered path is automatically added back to the routing table and used by the load balancer. The load balancer automatically adds routes for each path to the routing table and balances traffic across the configured interfaces, determined by interface health and weight.

In a minimal, configuration the following must be provided:

- an interface with a nexthop
- one rule with a LAN (inbound-interface) and the WAN (interface).

Let's assume we have two DHCP WAN interfaces and one LAN (eth2):

```
set load-balancing wan interface-health eth0 nexthop 'dhcp'
set load-balancing wan interface-health eth1 nexthop 'dhcp'
set load-balancing wan rule 1 inbound-interface 'eth2'
set load-balancing wan rule 1 interface eth0
set load-balancing wan rule 1 interface eth1
```

8.5.1 Balancing Rules

Interfaces, their weight and the type of traffic to be balanced are defined in numbered balancing rule sets. The rule sets are executed in numerical order against outgoing packets. In case of a match the packet is sent through an interface specified in the matching rule. If a packet doesn't match any rule it is sent by using the system routing table. Rule numbers can't be changed.

Create a load balancing rule, it can be a number between 1 and 9999:

```
vyos@vyos# set load-balancing wan rule 1
Possible completions:
description          Description for this rule
> destination        Destination
exclude              Exclude packets matching this rule from wan load balance
failover              Enable failover for packets matching this rule from wan load_
↪balance
inbound-interface    Inbound interface name (e.g., "eth0") [REQUIRED]
+> interface          Interface name [REQUIRED]
> limit              Enable packet limit for this rule
```

(continues on next page)

(continued from previous page)

```

per-packet-balancing  Option to match traffic per-packet instead of the default, ↵
↳ per-flow
protocol              Protocol to match
> source              Source information

```

Interface weight

Let's expand the example from above and add weight to the interfaces. The bandwidth from eth0 is larger than eth1. Per default, outbound traffic is distributed randomly across available interfaces. Weights can be assigned to interfaces to influence the balancing.

```

set load-balancing wan rule 1 interface eth0 weight 2
set load-balancing wan rule 1 interface eth1 weight 1

```

66% of traffic is routed to eth0, eth1 gets 33% of traffic.

Rate limit

A packet rate limit can be set for a rule to apply the rule to traffic above or below a specified threshold. To configure the rate limiting use:

```

set load-balancing wan rule <rule> limit <parameter>

```

- **burst:** Number of packets allowed to overshoot the limit within period. Default 5.
- **period:** Time window for rate calculation. Possible values: `second` (one second), `minute` (one minute), `hour` (one hour). Default is `second`.
- **rate:** Number of packets. Default 5.
- **threshold:** below or above the specified rate limit.

Flow and packet-based balancing

Outgoing traffic is balanced in a flow-based manner. A connection tracking table is used to track flows by their source address, destination address and port. Each flow is assigned to an interface according to the defined balancing rules and subsequent packets are sent through the same interface. This has the advantage that packets always arrive in order if links with different speeds are in use.

Packet-based balancing can lead to a better balance across interfaces when out of order packets are no issue. Per-packet-based balancing can be set for a balancing rule with:

```

set load-balancing wan rule <rule> per-packet-balancing

```

Exclude traffic

To exclude traffic from load balancing, traffic matching an exclude rule is not balanced but routed through the system routing table instead:

```

set load-balancing wan rule <rule> exclude

```

8.5.2 Health checks

The health of interfaces and paths assigned to the load balancer is periodically checked by sending ICMP packets (ping) to remote destinations, a TTL test or the execution of a user defined script. If an interface fails the health check it is removed from the load balancer's pool of interfaces. To enable health checking for an interface:

```
vyos@vyos# set load-balancing wan interface-health <interface>
Possible completions:
failure-count      Failure count
nexthop            Outbound interface nexthop address. Can be 'dhcp or ip address'
↪ [REQUIRED]
success-count      Success count
+> test           Rule number
```

Specify nexthop on the path to the destination, ipv4-address can be set to dhcp

```
set load-balancing wan interface-health <interface> nexthop <ipv4-address>
```

Set the number of health check failures before an interface is marked as unavailable, range for number is 1 to 10, default 1. Or set the number of successful health checks before an interface is added back to the interface pool, range for number is 1 to 10, default 1.

```
set load-balancing wan interface-health <interface> failure-count <number>
set load-balancing wan interface-health <interface> success-count <number>
```

Each health check is configured in its own test, tests are numbered and processed in numeric order. For multi target health checking multiple tests can be defined:

```
vyos@vyos# set load-balancing wan interface-health eth1 test 0
Possible completions:
resp-time          Ping response time (seconds)
target             Health target address
test-script        Path to user defined script
ttl-limit          Ttl limit (hop count)
type              WLB test type
```

- `resp-time`: the maximum response time for ping in seconds. Range 1...30, default 5
- `target`: the target to be sent ICMP packets to, address can be an IPv4 address or hostname
- `test-script`: A user defined script must return 0 to be considered successful and non-zero to fail. Scripts are located in `/config/scripts`, for different locations the full path needs to be provided
- `ttl-limit`: For the UDP TTL limit test the hop count limit must be specified. The limit must be shorter than the path length, an ICMP time expired message is needed to be returned for a successful test. default 1
- `type`: Specify the type of test. type can be ping, ttl or a user defined script

8.5.3 Source NAT rules

Per default, interfaces used in a load balancing pool replace the source IP of each outgoing packet with its own address to ensure that replies arrive on the same interface. This works through automatically generated source NAT (SNAT) rules, these rules are only applied to balanced traffic. In cases where this behaviour is not desired, the automatic generation of SNAT rules can be disabled:

```
set load-balancing wan disable-source-nat
```

8.5.4 Sticky Connections

Inbound connections to a WAN interface can be improperly handled when the reply is sent back to the client.

Upon reception of an incoming packet, when a response is sent, it might be desired to ensure that it leaves from the same interface as the inbound one. This can be achieved by enabling sticky connections in the load balancing:

```
set load-balancing wan sticky-connections inbound
```

8.5.5 Failover

In failover mode, one interface is set to be the primary interface and other interfaces are secondary or spare. Instead of balancing traffic across all healthy interfaces, only the primary interface is used and in case of failure, a secondary interface selected from the pool of available interfaces takes over. The primary interface is selected based on its weight and health, others become secondary interfaces. Secondary interfaces to take over a failed primary interface are chosen from the load balancer's interface pool, depending on their weight and health. Interface roles can also be selected based on rule order by including interfaces in balancing rules and ordering those rules accordingly. To put the load balancer in failover mode, create a failover rule:

```
set load-balancing wan rule <number> failover
```

Because existing sessions do not automatically fail over to a new path, the session table can be flushed on each connection state change:

```
set load-balancing wan flush-connections
```

Warning: Flushing the session table will cause other connections to fall back from flow-based to packet-based balancing until each flow is reestablished.

8.5.6 Script execution

A script can be run when an interface state change occurs. Scripts are run from /config/scripts, for a different location specify the full path:

```
set load-balancing wan hook script-name
```

Two environment variables are available:

- WLB_INTERFACE_NAME=[interfacename]: Interface to be monitored
- WLB_INTERFACE_STATE=[ACTIVE|FAILED]: Interface state

Warning: Blocking call with no timeout. System will become unresponsive if script does not return!

8.5.7 Handling and monitoring

Show WAN load balancer information including test types and targets. A character at the start of each line depicts the state of the test

- + successful
- - failed
- a blank indicates that no test has been carried out

```
vyos@vyos:~$ show wan-load-balance
Interface: eth0
Status: failed
Last Status Change: Tue Jun 11 20:12:19 2019
-Test: ping Target:
    Last Interface Success: 55s
    Last Interface Failure: 0s
    # Interface Failure(s): 5

Interface: eth1
Status: active
Last Status Change: Tue Jun 11 20:06:42 2019
+Test: ping Target:
    Last Interface Success: 0s
    Last Interface Failure: 6m26s
    # Interface Failure(s): 0
```

Show connection data of load balanced traffic:

```
vyos@vyos:~$ show wan-load-balance connection
conntrack v1.4.2 (conntrack-tools): 3 flow entries have been shown.
Type      State      Src          Dst          Packets Bytes

↪192.168.188.71
```

Restart

```
restart wan-load-balance
```

8.6 NAT

8.6.1 NAT44

NAT (Network Address Translation) is a common method of remapping one IP address space into another by modifying network address information in the IP header of packets while they are in transit across a traffic routing device. The technique was originally used as a shortcut to avoid the need to readdress every host when a network was moved. It has become a popular and essential tool in conserving global address space in the face of IPv4 address exhaustion. One Internet-routable IP address of a NAT gateway can be used for an entire private network.

IP masquerading is a technique that hides an entire IP address space, usually consisting of private IP addresses, behind a single IP address in another, usually public address space. The hidden addresses are changed into a single (public) IP address as the source address of the outgoing IP packets so they appear as originating not from the hidden host but from the routing device itself. Because of the popularity of this technique to conserve IPv4 address space, the term NAT has become virtually synonymous with IP masquerading.

As network address translation modifies the IP address information in packets, NAT implementations may vary in their specific behavior in various addressing cases and their effect on network traffic. The specifics of NAT behavior are not commonly documented by vendors of equipment containing NAT implementations.

The computers on an internal network can use any of the addresses set aside by the IANA (Internet Assigned Numbers Authority) for private addressing (see [RFC 1918](#)). These reserved IP addresses are not in use on the Internet, so an external machine will not directly route to them. The following addresses are reserved for private use:

- 10.0.0.0 to 10.255.255.255 (CIDR: 10.0.0.0/8)
- 172.16.0.0 to 172.31.255.255 (CIDR: 172.16.0.0/12)
- 192.168.0.0 to 192.168.255.255 (CIDR: 192.168.0.0/16)

If an ISP deploys a CGN (Carrier-grade NAT), and uses [RFC 1918](#) address space to number customer gateways, the risk of address collision, and therefore routing failures, arises when the customer network already uses an [RFC 1918](#) address space.

This prompted some ISPs to develop a policy within the ARIN (American Registry for Internet Numbers) to allocate new private address space for CGNs, but ARIN deferred to the IETF before implementing the policy indicating that the matter was not a typical allocation issue but a reservation of addresses for technical purposes (per [RFC 2860](#)).

IETF published [RFC 6598](#), detailing a shared address space for use in ISP CGN deployments that can handle the same network prefixes occurring both on inbound and outbound interfaces. ARIN returned address space to the IANA for this allocation.

The allocated address block is 100.64.0.0/10.

Devices evaluating whether an IPv4 address is public must be updated to recognize the new address space. Allocating more private IPv4 address space for NAT devices might prolong the transition to IPv6.

Overview

Different NAT Types

SNAT

SNAT (Source Network Address Translation) is the most common form of NAT and is typically referred to simply as NAT. To be more correct, what most people refer to as NAT is actually the process of PAT (Port Address Translation), or NAT overload. SNAT is typically used by internal users/private hosts to access the Internet - the source address is translated and thus kept private.

DNAT

DNAT (Destination Network Address Translation) changes the destination address of packets passing through the router, while *SNAT* changes the source address of packets. DNAT is typically used when an external (public) host needs to initiate a session with an internal (private) host. A customer needs to access a private service behind the routers public IP. A connection is established with the routers public IP address on a well known port and thus all traffic for this port is rewritten to address the internal (private) host.

Bidirectional NAT

This is a common scenario where both *SNAT* and *DNAT* are configured at the same time. It's commonly used then internal (private) hosts need to establish a connection with external resources and external systems need to access internal (private) resources.

NAT, Routing, Firewall Interaction

There is a very nice picture/explanation in the Vyatta documentation which should be rewritten here.

NAT Ruleset

NAT is configured entirely on a series of so called *rules*. Rules are numbered and evaluated by the underlying OS in numerical order! The rule numbers can be changes by utilizing the `rename` and `copy` commands.

Note: Changes to the NAT system only affect newly established connections. Already established connections are not affected.

Hint: When designing your NAT ruleset leave some space between consecutive rules for later extension. Your ruleset could start with numbers 10, 20, 30. You thus can later extend the ruleset and place new rules between existing ones.

Rules will be created for both *SNAT* and *DNAT*.

For *Bidirectional NAT* a rule for both *SNAT* and *DNAT* needs to be created.

Traffic Filters

Traffic Filters are used to control which packets will have the defined NAT rules applied. Five different filters can be applied within a NAT rule.

- **outbound-interface** - applicable only to *SNAT*. It configures the interface which is used for the outside traffic that this translation rule applies to.

Example:

```
set nat source rule 20 outbound-interface eth0
```

- **inbound-interface** - applicable only to *DNAT*. It configures the interface which is used for the inside traffic the translation rule applies to.

Example:

```
set nat destination rule 20 inbound-interface eth1
```

- **protocol** - specify which types of protocols this translation rule applies to. Only packets matching the specified protocol are NATed. By default this applies to *all* protocols.

Example:

- Set SNAT rule 20 to only NAT TCP and UDP packets
- Set DNAT rule 20 to only NAT UDP packets

```
set nat source rule 20 protocol tcp_udp
set nat destination rule 20 protocol udp
```

- **source** - specifies which packets the NAT translation rule applies to based on the packets source IP address and/or source port. Only matching packets are considered for NAT.

Example:

- Set SNAT rule 20 to only NAT packets arriving from the 192.0.2.0/24 network
- Set SNAT rule 30 to only NAT packets arriving from the 203.0.113.0/24 network with a source port of 80 and 443

```
set nat source rule 20 source address 192.0.2.0/24
set nat source rule 30 source address 203.0.113.0/24
set nat source rule 30 source port 80,443
```

- **destination** - specify which packets the translation will be applied to, only based on the destination address and/or port number configured.

Note: If no destination is specified the rule will match on any destination address and port.

Example:

- Configure SNAT rule (40) to only NAT packets with a destination address of 192.0.2.1.

```
set nat source rule 40 destination address 192.0.2.1
```

Address Conversion

Every NAT rule has a translation command defined. The address defined for the translation is the address used when the address information in a packet is replaced.

Source Address

For *SNAT* rules the packets source address will be replaced with the address specified in the translation command. A port translation can also be specified and is part of the translation address.

Note: The translation address must be set to one of the available addresses on the configured *outbound-interface* or it must be set to *masquerade* which will use the primary IP address of the *outbound-interface* as its translation address.

Note: When using NAT for a large number of host systems it recommended that a minimum of 1 IP address is used to NAT every 256 private host systems. This is due to the limit of 65,000 port numbers available for unique translations and a reserving an average of 200-300 sessions per host system.

Example:

- Define a discrete source IP address of 100.64.0.1 for SNAT rule 20
- Use address *masquerade* (the interfaces primary address) on rule 30
- For a large amount of private machines behind the NAT your address pool might to be bigger. Use any address in the range 100.64.0.10 - 100.64.0.20 on SNAT rule 40 when doing the translation

```
set nat source rule 20 translation address 100.64.0.1
set nat source rule 30 translation address 'masquerade'
set nat source rule 40 translation address 100.64.0.10-100.64.0.20
```

Destination Address

For *DNAT* rules the packets destination address will be replaced by the specified address in the *translation address* command.

Example:

- DNAT rule 10 replaces the destination address of an inbound packet with 192.0.2.10

```
set nat destination rule 10 translation address 192.0.2.10
```

Configuration Examples

To setup SNAT, we need to know:

- The internal IP addresses we want to translate
- The outgoing interface to perform the translation on
- The external IP address to translate to

In the example used for the Quick Start configuration above, we demonstrate the following configuration:

```
set nat source rule 100 outbound-interface 'eth0'
set nat source rule 100 source address '192.168.0.0/24'
set nat source rule 100 translation address 'masquerade'
```

Which generates the following configuration:

```
rule 100 {
    outbound-interface eth0
    source {
        address 192.168.0.0/24
    }
    translation {
        address masquerade
    }
}
```

In this example, we use **masquerade** as the translation address instead of an IP address. The **masquerade** target is effectively an alias to say “use whatever IP address is on the outgoing interface”, rather than a statically configured IP address. This is useful if you use DHCP for your outgoing interface and do not know what the external address will be.

When using NAT for a large number of host systems it recommended that a minimum of 1 IP address is used to NAT every 256 host systems. This is due to the limit of 65,000 port numbers available for unique translations and a reserving an average of 200-300 sessions per host system.

Example: For an ~8,000 host network a source NAT pool of 32 IP addresses is recommended.

A pool of addresses can be defined by using a hyphen between two IP addresses:

```
set nat source rule 100 translation address '203.0.113.32-203.0.113.63'
```

Avoiding “leaky” NAT

Linux netfilter will not NAT traffic marked as INVALID. This often confuses people into thinking that Linux (or specifically VyOS) has a broken NAT implementation because non-NATed traffic is seen leaving an external interface. This is actually working as intended, and a packet capture of the “leaky” traffic should reveal that the traffic is either an additional TCP “RST”, “FIN,ACK”, or “RST,ACK” sent by client systems after Linux netfilter considers the connection closed. The most common is the additional TCP RST some host implementations send after terminating a connection (which is implementation-specific).

In other words, connection tracking has already observed the connection be closed and has transition the flow to INVALID to prevent attacks from attempting to reuse the connection.

You can avoid the “leaky” behavior by using a firewall policy that drops “invalid” state packets.

Having control over the matching of INVALID state traffic, e.g. the ability to selectively log, is an important troubleshooting tool for observing broken protocol behavior. For this reason, VyOS does not globally drop invalid state traffic, instead allowing the operator to make the determination on how the traffic is handled.

Hairpin NAT/NAT Reflection

A typical problem with using NAT and hosting public servers is the ability for internal systems to reach an internal server using it’s external IP address. The solution to this is usually the use of split-DNS to correctly point host systems to the internal address when requests are made internally. Because many smaller networks lack DNS infrastructure, a work-around is commonly deployed to facilitate the traffic by NATing the request from internal hosts to the source address of the internal interface on the firewall.

This technique is commonly referred to as NAT Reflection or Hairpin NAT.

Example:

- Redirect Microsoft RDP traffic from the outside (WAN, external) world via *DNAT* in rule 100 to the internal, private host 192.0.2.40.

- Redirect Microsoft RDP traffic from the internal (LAN, private) network via *DNAT* in rule 110 to the internal, private host 192.0.2.40. We also need a *SNAT* rule 110 for the reverse path of the traffic. The internal network 192.0.2.0/24 is reachable via interface *eth0.10*.

```
set nat destination rule 100 description 'Regular destination NAT from external'
set nat destination rule 100 destination port '3389'
set nat destination rule 100 inbound-interface 'pppoe0'
set nat destination rule 100 protocol 'tcp'
set nat destination rule 100 translation address '192.0.2.40'

set nat destination rule 110 description 'NAT Reflection: INSIDE'
set nat destination rule 110 destination port '3389'
set nat destination rule 110 inbound-interface 'eth0.10'
set nat destination rule 110 protocol 'tcp'
set nat destination rule 110 translation address '192.0.2.40'

set nat source rule 110 description 'NAT Reflection: INSIDE'
set nat source rule 110 destination address '192.0.2.0/24'
set nat source rule 110 outbound-interface 'eth0.10'
set nat source rule 110 protocol 'tcp'
set nat source rule 110 source address '192.0.2.0/24'
set nat source rule 110 translation address 'masquerade'
```

Which results in a configuration of:

```
vyos@vyos# show nat
destination {
    rule 100 {
        description "Regular destination NAT from external"
        destination {
            port 3389
        }
        inbound-interface pppoe0
        protocol tcp
        translation {
            address 192.0.2.40
        }
    }
    rule 110 {
        description "NAT Reflection: INSIDE"
        destination {
            port 3389
        }
        inbound-interface eth0.10
        protocol tcp
        translation {
            address 192.0.2.40
        }
    }
}
source {
    rule 110 {
        description "NAT Reflection: INSIDE"
        destination {
            address 192.0.2.0/24
        }
        outbound-interface eth0.10
        protocol tcp
```

(continues on next page)

(continued from previous page)

```
source {
    address 192.0.2.0/24
}
translation {
    address masquerade
}
}
```

Destination NAT

DNAT is typically referred to as a **Port Forward**. When using VyOS as a NAT router and firewall, a common configuration task is to redirect incoming traffic to a system behind the firewall.

In this example, we will be using the example Quick Start configuration above as a starting point.

To setup a destination NAT rule we need to gather:

- The interface traffic will be coming in on;
- The protocol and port we wish to forward;
- The IP address of the internal system we wish to forward traffic to.

In our example, we will be forwarding web server traffic to an internal web server on 192.168.0.100. HTTP traffic makes use of the TCP protocol on port 80. For other common port numbers, see: https://en.wikipedia.org/wiki/List_of_TCP_and_UDP_port_numbers

Our configuration commands would be:

```
set nat destination rule 10 description 'Port Forward: HTTP to 192.168.0.100'
set nat destination rule 10 destination port '80'
set nat destination rule 10 inbound-interface 'eth0'
set nat destination rule 10 protocol 'tcp'
set nat destination rule 10 translation address '192.168.0.100'
```

Which would generate the following NAT destination configuration:

```
nat {
    destination {
        rule 10 {
            description "Port Forward: HTTP to 192.168.0.100"
            destination {
                port 80
            }
            inbound-interface eth0
            protocol tcp
            translation {
                address 192.168.0.100
            }
        }
    }
}
```

Note: If forwarding traffic to a different port than it is arriving on, you may also configure the translation port using *set nat destination rule [n] translation port*.

This establishes our Port Forward rule, but if we created a firewall policy it will likely block the traffic.

It is important to note that when creating firewall rules that the DNAT translation occurs **before** traffic traverses the firewall. In other words, the destination address has already been translated to 192.168.0.100.

So in our firewall policy, we want to allow traffic coming in on the outside interface, destined for TCP port 80 and the IP address of 192.168.0.100.

```
set firewall name OUTSIDE-IN rule 20 action 'accept'
set firewall name OUTSIDE-IN rule 20 destination address '192.168.0.100'
set firewall name OUTSIDE-IN rule 20 destination port '80'
set firewall name OUTSIDE-IN rule 20 protocol 'tcp'
set firewall name OUTSIDE-IN rule 20 state new 'enable'
```

This would generate the following configuration:

```
rule 20 {
    action accept
    destination {
        address 192.168.0.100
        port 80
    }
    protocol tcp
    state {
        new enable
    }
}
```

Note: If you have configured the *INSIDE-OUT* policy, you will need to add additional rules to permit inbound NAT traffic.

1-to-1 NAT

Another term often used for DNAT is **1-to-1 NAT**. For a 1-to-1 NAT configuration, both DNAT and SNAT are used to NAT all traffic from an external IP address to an internal IP address and vice-versa.

Typically, a 1-to-1 NAT rule omits the destination port (all ports) and replaces the protocol with either **all** or **ip**.

Then a corresponding SNAT rule is created to NAT outgoing traffic for the internal IP to a reserved external IP. This dedicates an external IP address to an internal IP address and is useful for protocols which don't have the notion of ports, such as GRE.

Here's an extract of a simple 1-to-1 NAT configuration with one internal and one external interface:

```
set interfaces ethernet eth0 address '192.168.1.1/24'
set interfaces ethernet eth0 description 'Inside interface'
set interfaces ethernet eth1 address '192.0.2.30/24'
set interfaces ethernet eth1 description 'Outside interface'
set nat destination rule 2000 description '1-to-1 NAT example'
set nat destination rule 2000 destination address '192.0.2.30'
set nat destination rule 2000 inbound-interface 'eth1'
set nat destination rule 2000 translation address '192.168.1.10'
set nat source rule 2000 description '1-to-1 NAT example'
set nat source rule 2000 outbound-interface 'eth1'
set nat source rule 2000 source address '192.168.1.10'
set nat source rule 2000 translation address '192.0.2.30'
```

Firewall rules are written as normal, using the internal IP address as the source of outbound rules and the destination of inbound rules.

NAT before VPN

Some application service providers (ASPs) operate a VPN gateway to provide access to their internal resources, and require that a connecting organisation translate all traffic to the service provider network to a source address provided by the ASP.

Example Network

Here's one example of a network environment for an ASP. The ASP requests that all connections from this company should come from 172.29.41.89 - an address that is assigned by the ASP and not in use at the customer site.

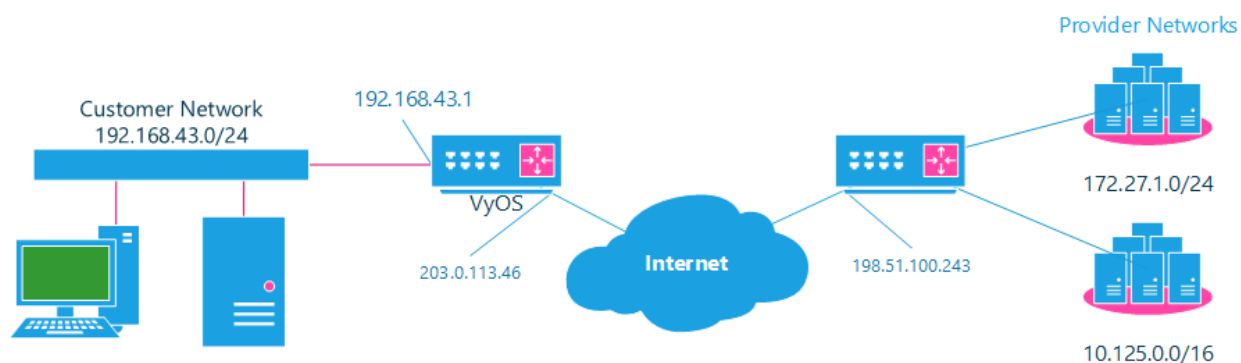

Fig. 1: NAT before VPN Topology

Configuration

The required configuration can be broken down into 4 major pieces:

- A dummy interface for the provider-assigned IP;
- NAT (specifically, Source NAT);
- IPSec IKE and ESP Groups;
- IPSec VPN tunnels.

Dummy interface

The dummy interface allows us to have an equivalent of the Cisco IOS Loopback interface - a router-internal interface we can use for IP addresses the router must know about, but which are not actually assigned to a real network.

We only need a single step for this interface:

```
set interfaces dummy dum0 address '172.29.41.89/32'
```

NAT Configuration

```
set nat source rule 110 description 'Internal to ASP'
set nat source rule 110 destination address '172.27.1.0/24'
set nat source rule 110 outbound-interface 'any'
set nat source rule 110 source address '192.168.43.0/24'
set nat source rule 110 translation address '172.29.41.89'
set nat source rule 120 description 'Internal to ASP'
set nat source rule 120 destination address '10.125.0.0/16'
set nat source rule 120 outbound-interface 'any'
set nat source rule 120 source address '192.168.43.0/24'
set nat source rule 120 translation address '172.29.41.89'
```

IPSec IKE and ESP

The ASP has documented their IPSec requirements:

- IKE Phase:
 - aes256 Encryption
 - sha256 Hashes
- ESP Phase:
 - aes256 Encryption
 - sha256 Hashes
 - DH Group 14

Additionally, we want to use VPNs only on our eth1 interface (the external interface in the image above)

```
set vpn ipsec ike-group my-ike ikev2-reauth 'no'
set vpn ipsec ike-group my-ike key-exchange 'ikev1'
set vpn ipsec ike-group my-ike lifetime '7800'
set vpn ipsec ike-group my-ike proposal 1 dh-group '14'
set vpn ipsec ike-group my-ike proposal 1 encryption 'aes256'
set vpn ipsec ike-group my-ike proposal 1 hash 'sha256'

set vpn ipsec esp-group my-esp compression 'disable'
set vpn ipsec esp-group my-esp lifetime '3600'
set vpn ipsec esp-group my-esp mode 'tunnel'
set vpn ipsec esp-group my-esp pfs 'disable'
set vpn ipsec esp-group my-esp proposal 1 encryption 'aes256'
set vpn ipsec esp-group my-esp proposal 1 hash 'sha256'

set vpn ipsec ipsec-interfaces interface 'eth1'
```

IPSec VPN Tunnels

We'll use the IKE and ESP groups created above for this VPN. Because we need access to 2 different subnets on the far side, we will need two different tunnels. If you changed the names of the ESP group and IKE group in the previous step, make sure you use the correct names here too.

```

set vpn ipsec site-to-site peer 198.51.100.243 authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer 198.51.100.243 authentication pre-shared-secret
↪ 'PASSWORD IS HERE'
set vpn ipsec site-to-site peer 198.51.100.243 connection-type 'initiate'
set vpn ipsec site-to-site peer 198.51.100.243 default-esp-group 'my-esp'
set vpn ipsec site-to-site peer 198.51.100.243 ike-group 'my-ike'
set vpn ipsec site-to-site peer 198.51.100.243 ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer 198.51.100.243 local-address '203.0.113.46'
set vpn ipsec site-to-site peer 198.51.100.243 tunnel 0 local prefix '172.29.41.89/32'
set vpn ipsec site-to-site peer 198.51.100.243 tunnel 0 remote prefix '172.27.1.0/24'
set vpn ipsec site-to-site peer 198.51.100.243 tunnel 1 local prefix '172.29.41.89/32'
set vpn ipsec site-to-site peer 198.51.100.243 tunnel 1 remote prefix '10.125.0.0/16'

```

Testing and Validation

If you've completed all the above steps you no doubt want to see if it's all working.

Start by checking for IPSec SAs (Security Associations) with:

```

$ show vpn ipsec sa

```

Peer ID / IP	Local ID / IP	Tunnel	State	Bytes Out/In	Encrypt	Hash	NAT-T	A-Time	L-Time	Proto
198.51.100.243	203.0.113.46	0	up	0.0/0.0	aes256	sha256	no	1647	3600	all
		1	up	0.0/0.0	aes256	sha256	no	865	3600	all

That looks good - we defined 2 tunnels and they're both up and running.

8.6.2 NAT66(NPTv6)

NPTv6 (IPv6-to-IPv6 Network Prefix Translation) is an address translation technology based on IPv6 networks, used to convert an IPv6 address prefix in an IPv6 message into another IPv6 address prefix. We call this address translation method NAT66. Devices that support the NAT66 function are called NAT66 devices, which can provide NAT66 source and destination address translation functions.

Overview

Different NAT Types

SNAT66

SNPTv6 (Source IPv6-to-IPv6 Network Prefix Translation) The conversion function is mainly used in the following scenarios:

- A single internal network and external network. Use the NAT66 device to connect a single internal network and public network, and the hosts in the internal network use IPv6 address prefixes that only support routing within the local range. When a host in the internal network accesses the external network, the source IPv6 address prefix in the message will be converted into a global unicast IPv6 address prefix by the NAT66 device.

- Redundancy and load sharing. There are multiple NAT66 devices at the edge of an IPv6 network to another IPv6 network. The path through the NAT66 device to another IPv6 network forms an equivalent route, and traffic can be load-shared on these NAT66 devices. In this case, you can configure the same source address translation rules on these NAT66 devices, so that any NAT66 device can handle IPv6 traffic between different sites.
- Multi-homed. In a multi-homed network environment, the NAT66 device connects to an internal network and simultaneously connects to different external networks. Address translation can be configured on each external network side interface of the NAT66 device to convert the same internal network address into different external network addresses, and realize the mapping of the same internal address to multiple external addresses.

DNAT66

The DNPTv6 (Destination IPv6-to-IPv6 Network Prefix Translation) destination address translation function is used in scenarios where the server in the internal network provides services to the external network, such as providing Web services or FTP services to the external network. By configuring the mapping relationship between the internal server address and the external network address on the external network side interface of the NAT66 device, external network users can access the internal network server through the designated external network address.

Prefix Conversion

Source Prefix

Every SNAT66 rule has a translation command defined. The prefix defined for the translation is the prefix used when the address information in a packet is replaced.

The *SNAT66* rule replaces the source address of the packet and calculates the converted address using the prefix specified in the rule.

Example:

- Convert the address prefix of a single *fc01::/64* network to *fc00::/64*
- Output from *eth0* network interface

```
set nat66 source rule 1 outbound-interface 'eth0'
set nat66 source rule 1 source prefix 'fc01::/64'
set nat66 source rule 1 translation address 'fc00::/64'
```

Destination Prefix

For the *DNAT66* rule, the destination address of the packet is replaced by the address calculated from the specified address or prefix in the *translation address* command

Example:

- Convert the address prefix of a single *fc00::/64* network to *fc01::/64*
- Input from *eth0* network interface

```
set nat66 destination rule 1 inbound-interface 'eth0'
set nat66 destination rule 1 destination address 'fc00::/64'
set nat66 destination rule 1 translation address 'fc01::/64'
```

Configuration Examples

Use the following topology to build a nat66 based isolated network between internal and external networks (dynamic prefix is not supported):

R1:

```

set interfaces ethernet eth0 ipv6 address autoconf
set interfaces ethernet eth1 address 'fc01::1/64'
set nat66 destination rule 1 destination address 'fc00:470:f1cd:101::/64'
set nat66 destination rule 1 inbound-interface 'eth0'
set nat66 destination rule 1 translation address 'fc01::/64'
set nat66 source rule 1 outbound-interface 'eth0'
set nat66 source rule 1 source prefix 'fc01::/64'
set nat66 source rule 1 translation address 'fc00:470:f1cd:101::/64'

```

R2:

```

set interfaces bridge br1 address 'fc01::2/64'
set interfaces bridge br1 member interface eth0
set interfaces bridge br1 member interface eth1
set protocols static route6 ::/0 next-hop fc01::1
set service router-advert interface br1 prefix ::/0

```

:lastproofread:2021-07-12

8.7 Policy

Policies are used for filtering and traffic management. With policies, network administrators could filter and treat traffic according to their needs.

There could be a wide range of routing policies. Some examples are listed below:

- Filter traffic based on source/destination address.
- Set some metric to routes learned from a particular neighbor.
- Set some attributes (like AS PATH or Community value) to advertised routes to neighbors.
- Prefer a specific routing protocol routes over another routing protocol running on the same router.

Policies, in VyOS, are implemented using FRR filtering and route maps. Detailed information of FRR could be found in <http://docs.frrouting.org/>

8.7.1 Policy Sections

Access List Policy

Filtering is used for both input and output of the routing information. Once filtering is defined, it can be applied in any direction. VyOS makes filtering possible using acls and prefix lists.

Basic filtering can be done using access-list and access-list6.

Configuration

Access Lists

```
set policy access-list <acl_number>
```

This command creates the new access list policy, where <acl_number> must be a number from 1 to 2699.

```
set policy access-list <acl_number> description <text>
```

Set description for the access list.

```
set policy access-list <acl_number> rule <1-65535> action <permit|deny>
```

This command creates a new rule in the access list and defines an action.

```
set policy access-list <acl_number> rule <1-65535> <destination|source>  
<any|host|inverse-mask|network>
```

This command defines matching parameters for access list rule. Matching criteria could be applied to destination or source parameters:

- any: any IP address to match.
- host: single host IP address to match.
- inverse-match: network/netmask to match (requires network be defined).
- network: network/netmask to match (requires inverse-match be defined).

IPv6 Access List

Basic filtering could also be applied to IPv6 traffic.

```
set policy access-list6 <text>
```

This command creates the new IPv6 access list, identified by <text>

```
set policy access-list6 <text> description <text>
```

Set description for the IPv6 access list.

```
set policy access-list6 <text> rule <1-65535> action <permit|deny>
```

This command creates a new rule in the IPv6 access list and defines an action.

```
set policy access-list6 <text> rule <1-65535> source <any|exact-match|network>
```

This command defines matching parameters for IPv6 access list rule. Matching criteria could be applied to source parameters:

- any: any IPv6 address to match.
- exact-match: exact match of the network prefixes.
- network: network/netmask to match (requires inverse-match be defined) BUG, NO invert-match option in access-list6

Prefix List Policy

Prefix lists provides the most powerful prefix based filtering mechanism. In addition to access-list functionality, ip prefix-list has prefix length range specification.

If no ip prefix list is specified, it acts as permit. If ip prefix list is defined, and no match is found, default deny is applied.

Prefix filtering can be done using prefix-list and prefix-list6.

Configuration

Prefix Lists

```
set policy prefix-list <text>
```

This command creates the new prefix-list policy, identified by <text>.

```
set policy prefix-list <text> description <text>
```

Set description for the prefix-list policy.

```
set policy prefix-list <text> rule <1-65535> action <permit|deny>
```

This command creates a new rule in the prefix-list and defines an action.

```
set policy prefix-list <text> rule <1-65535> description <text>
```

Set description for rule in the prefix-list.

```
set policy prefix-list <text> rule <1-65535> prefix <x.x.x.x/x>
```

Prefix to match against.

```
set policy prefix-list <text> rule <1-65535> ge <0-32>
```

Netmask greater than length.

```
set policy prefix-list <text> rule <1-65535> le <0-32>
```

Netmask less than length

IPv6 Prefix Lists

set policy prefix-list6 <text>

This command creates the new IPv6 prefix-list policy, identified by <text>.

set policy prefix-list6 <text> description <text>

Set description for the IPv6 prefix-list policy.

set policy prefix-list6 <text> rule <1-65535> action <permit|deny>

This command creates a new rule in the IPv6 prefix-list and defines an action.

set policy prefix-list6 <text> rule <1-65535> description <text>

Set description for rule in IPv6 prefix-list.

set policy prefix-list6 <text> rule <1-65535> prefix <h:h:h:h:h:h:h/x>

IPv6 prefix.

set policy prefix-list6 <text> rule <1-65535> ge <0-128>

Netmask greater than length.

set policy prefix-list6 <text> rule <1-65535> le <0-128>

Netmask less than length

Route Policy

Route and IPv6 route policies are defined in this section. This route policies can then be associated to interfaces.

Configuration

Route

set policy route <text>

This command creates a new route policy, identified by <text>.

set policy route <text> description <text>

Set description for the route policy.

set policy route <text> enable-default-log

Option to log packets hitting default-action.

set policy route <text> rule <1-9999> description <text>

Set description for rule in route policy.

set policy route <text> rule <1-9999> action drop

Set rule action to drop.

set policy route <text> rule <1-9999> destination address <match_criteria>

Set match criteria based on destination address, where <match_criteria> could be:

- <x.x.x.x>: IP address to match.
- <x.x.x.x/x>: Subnet to match.

- <x.x.x.x>-<x.x.x.x>: IP range to match.
- !<x.x.x.x>: Match everything except the specified address.
- !<x.x.x.x/x>: Match everything except the specified subnet.
- !<x.x.x.x>-<x.x.x.x>: Match everything except the specified range.

```
set policy route <text> rule <1-9999> destination group <address-group|network-group|port-
<text>
```

Set destination match criteria based on groups, where <text> would be the group name/identifier.

```
set policy route <text> rule <1-9999> destination port <match_criteria>
```

Set match criteria based on destination port, where <match_criteria> could be:

- <port name>: Named port (any name in /etc/services, e.g., http).
- <1-65535>: Numbered port.
- <start>-<end>: Numbered port range (e.g., 1001-1005).

Multiple destination ports can be specified as a comma-separated list. The whole list can also be “negated” using ‘!’. For example: ‘!22,telnet,http,123,1001-1005’

```
set policy route <text> rule <1-9999> disable
```

Option to disable rule.

```
set policy route <text> rule <1-9999> fragment <match-grag|match-non-frag>
```

Set IP fragment match, where:

- match-frag: Second and further fragments of fragmented packets.
- match-non-frag: Head fragments or unfragmented packets.

```
set policy route <text> rule <1-9999> icmp <code|type|type-name>
```

Set ICMP match criterias, based on code and/or types. Types could be referenced by number or by name.

```
set policy route <text> rule <1-9999> ipsec <match-ipsec|match-none>
```

Set IPSec inbound match criterias, where:

- match-ipsec: match inbound IPsec packets.
- match-none: match inbound non-IPsec packets.

```
set policy route <text> rule <1-9999> limit burst <0-4294967295>
```

Set maximum number of packets to allow in excess of rate

```
set policy route <text> rule <1-9999> limit rate <text>
```

Set maximum average matching rate. Format for rate: integer/time_unit, where time_unit could be any one of second, minute, hour or day. For example 1/second implies rule to be matched at an average of once per second.

```
set policy route <text> rule <1-9999> log <enable|disable>
```

Option to enable or disable log matching rule.

```
set policy route <text> rule <1-9999> log <text>
```

Option to log matching rule.

```
set policy route <text> rule <1-9999> protocol <text|0-255|tcp_udp|all|!
protocol>
```

Set protocol to match. Protocol name in /etc/protocols or protocol number, or “tcp_udp” or “all”. Also, protocol could be denied by using !.

```
set policy route <text> rule <1-9999> recent <count|time> <1-255|0-4294967295>
```

Set parameters for matching recently seen sources. This match could be used by setting count (source address seen more than <1-255> times) and/or time (source address seen in the last <0-4294967295> seconds).

```
set policy route <text> rule <1-9999> set dscp <0-63>
```

Set packet modifications: Packet Differentiated Services Codepoint (DSCP)

```
set policy route <text> rule <1-9999> set mark <1-2147483647>
```

Set packet modifications: Packet marking

```
set policy route <text> rule <1-9999> set table <main|1-200>
```

Set packet modifications: Routing table to forward packet with.

```
set policy route <text> rule <1-9999> set tcp-mss <500-1460>
```

Set packet modifications: Explicitly set TCP Maximum segment size value.

```
set policy route <text> rule <1-9999> source address <match_criteria>
```

Set match criteria based on source address, where <match_criteria> could be:

- <x.x.x.x>: IP address to match.
- <x.x.x.x/x>: Subnet to match.
- <x.x.x.x>-<x.x.x.x>: IP range to match.
- !<x.x.x.x>: Match everything except the specified address.
- !<x.x.x.x/x>: Match everything except the specified subnet.
- !<x.x.x.x>-<x.x.x.x>: Match everything except the specified range.

```
set policy route <text> rule <1-9999> source group <address-group|network-group|port-group>  
<text>
```

Set source match criteria based on groups, where <text> would be the group name/identifier.

```
set policy route <text> rule <1-9999> source port <match_criteria>
```

Set match criteria based on source port, where <match_criteria> could be:

- <port name>: Named port (any name in /etc/services, e.g., http).
- <1-65535>: Numbered port.
- <start>-<end>: Numbered port range (e.g., 1001-1005).

Multiple source ports can be specified as a comma-separated list. The whole list can also be “negated” using ‘!’. For example: ‘!22,telnet,http,123,1001-1005’

```
set policy route <text> rule <1-9999> state <established|invalid|new|related>  
<disable|enable>
```

Set match criteria based on session state.

```
set policy route <text> rule <1-9999> tcp flags <text>
```

Set match criteria based on tcp flags. Allowed values for TCP flags: SYN ACK FIN RST URG PSH ALL. When specifying more than one flag, flags should be comma-separated. For example : value of ‘SYN,!ACK,!FIN,!RST’ will only match packets with the SYN flag set, and the ACK, FIN and RST flags unset.

set policy route <text> rule <1-9999> time monthdays <text>

Set monthdays to match rule on. Format for monthdays: 2,12,21. To negate add ! at the front eg. !2,12,21

set policy route <text> rule <1-9999> time startdate <text>

Set date to start matching rule. Format for date: yyyy-mm-dd. To specify time of date with startdate, append 'T' to date followed by time in 24 hour notation hh:mm:ss. For eg startdate value of 2009-01-21T13:30:00 refers to 21st Jan 2009 with time 13:30:00.

set policy route <text> rule <1-9999> time starttime <text>

Set time of day to start matching rule. Format of time: hh:mm:ss using 24 hours notation.

set policy route <text> rule <1-9999> time stopdate <text>

Set date to stop matching rule. Format for date: yyyy-mm-dd. To specify time of date with stopdate, append 'T' to date followed by time in 24 hour notation hh:mm:ss. For eg startdate value of 2009-01-21T13:30:00 refers to 21st Jan 2009 with time 13:30:00.

set policy route <text> rule <1-9999> time stoptime <text>

Set time of day to stop matching rule. Format of time: hh:mm:ss using 24 hours notation.

set policy route <text> rule <1-9999> time utc

Interpret times for startdate, stopdate, starttime and stoptime to be UTC.

set policy route <text> rule <1-9999> time weekdays

Weekdays to match rule on. Format for weekdays: Mon,Thu,Sat. To negate add ! at the front eg. !Mon,Thu,Sat.

IPv6 Route

set policy ipv6-route <text>

This command creates a new IPv6 route policy, identified by <text>.

set policy ipv6-route <text> description <text>

Set description for the IPv6 route policy.

set policy ipv6-route <text> enable-default-log

Option to log packets hitting default-action.

set policy ipv6-route <text> rule <1-9999> action drop

Set rule action to drop.

set policy ipv6-route <text> rule <1-9999> description <text>

Set description for rule in IPv6 route policy.

**set policy ipv6-route <text> rule <1-9999> destination address
<match_criteria>**

Set match criteria based on destination IPv6 address, where <match_criteria> could be:

- <h:h:h:h:h:h>: IPv6 address to match.
- <h:h:h:h:h:h/x>: IPv6 prefix to match.
- <h:h:h:h:h:h>-<h:h:h:h:h:h>: IPv6 range to match.
- !<h:h:h:h:h:h>: Match everything except the specified address.

- `!<h:h:h:h:h:h:h/x>`: Match everything except the specified prefix.
- `!<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>`: Match everything except the specified range.

set policy ipv6-route <text> rule <1-9999> destination port <match_criteria>

Set match criteria based on destination port, where <match_criteria> could be:

- `<port name>`: Named port (any name in /etc/services, e.g., http).
- `<1-65535>`: Numbered port.
- `<start>-<end>`: Numbered port range (e.g., 1001-1005).

Multiple destination ports can be specified as a comma-separated list. The whole list can also be “negated” using ‘!’. For example: ‘!22,telnet,http,123,1001-1005’.

set policy ipv6-route <text> rule <1-9999> disable

Option to disable rule.

set policy ipv6-route <text> rule <1-9999> icmpv6 type <icmpv6_typ>

Set ICMPv6 match criterias, based on ICMPv6 type/code name.

set policy ipv6-route <text> rule <1-9999> ipsec <match-ipsec|match-none>

Set IPsec inbound match criterias, where:

- `match-ipsec`: match inbound IPsec packets.
- `match-none`: match inbound non-IPsec packets.

set policy ipv6-route <text> rule <1-9999> limit burst <0-4294967295>

Set maximum number of packets to allow in excess of rate

set policy ipv6-route <text> rule <1-9999> limit rate <text>

Set maximum average matching rate. Format for rate: integer/time_unit, where time_unit could be any one of second, minute, hour or day. For example 1/second implies rule to be matched at an average of once per second.

set policy ipv6-route <text> rule <1-9999> log <enable|disable>

Option to enable or disable log matching rule.

set policy ipv6-route <text> rule <1-9999> log <text>

Option to log matching rule.

set policy ipv6-route <text> rule <1-9999> protocol <text|0-255|tcp_udp|all|!protocol>

Set IPv6 protocol to match. IPv6 protocol name from /etc/protocols or protocol number, or “tcp_udp” or “all”. Also, protocol could be denied by using !.

**set policy ipv6-route <text> rule <1-9999> recent <count|time>
<1-255|0-4294967295>**

Set parameters for matching recently seen sources. This match could be used by setting count (source address seen more than <1-255> times) and/or time (source address seen in the last <0-4294967295> seconds).

set policy ipv6-route <text> rule <1-9999> set dscp <0-63>

Set packet modifications: Packet Differentiated Services Codepoint (DSCP)

set policy ipv6-route <text> rule <1-9999> set mark <1-2147483647>

Set packet modifications: Packet marking.

```
set policy ipv6-route <text> rule <1-9999> set table <main|1-200>
```

Set packet modifications: Routing table to forward packet with.

```
set policy ipv6-route <text> rule <1-9999> set tcp-mss <pmtu|500-1460>
```

Set packet modifications: pmtu option automatically set to Path Maximum Transfer Unit minus 60 bytes. Otherwise, explicitly set TCP MSS value from 500 to 1460.

```
set policy ipv6-route <text> rule <1-9999> source address <match_criteria>
```

Set match criteria based on IPv6 source address, where <match_criteria> could be:

- <h:h:h:h:h:h:h>: IPv6 address to match
- <h:h:h:h:h:h:h/x>: IPv6 prefix to match
- <h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>: IPv6 range to match
- !<h:h:h:h:h:h:h>: Match everything except the specified address
- !<h:h:h:h:h:h:h/x>: Match everything except the specified prefix
- !<h:h:h:h:h:h:h>-<h:h:h:h:h:h:h>: Match everything except the specified range

```
set policy ipv6-route <text> rule <1-9999> source mac-address <MAC_address|!MAC_address>
```

Set source match criteria based on MAC address. Declare specific MAC address to match, or match everything except the specified MAC.

```
set policy ipv6-route <text> rule <1-9999> source port <match_criteria>
```

Set match criteria based on source port, where <match_criteria> could be:

- <port name>: Named port (any name in /etc/services, e.g., http).
- <1-65535>: Numbered port.
- <start>-<end>: Numbered port range (e.g., 1001-1005).

Multiple source ports can be specified as a comma-separated list. The whole list can also be “negated” using ‘!’. For example: ‘!22,telnet,http,123,1001-1005’.

```
set policy ipv6-route <text> rule <1-9999> state <established|invalid|new|related>
<disable|enable>
```

Set match criteria based on session state.

```
set policy ipv6-route <text> rule <1-9999> tcp flags <text>
```

Set match criteria based on tcp flags. Allowed values for TCP flags: SYN ACK FIN RST URG PSH ALL. When specifying more than one flag, flags should be comma-separated. For example : value of ‘SYN,!ACK,!FIN,!RST’ will only match packets with the SYN flag set, and the ACK, FIN and RST flags unset.

```
set policy ipv6-route <text> rule <1-9999> time monthdays <text>
```

Set monthdays to match rule on. Format for monthdays: 2,12,21. To negate add ! at the front eg. !2,12,21

```
set policy ipv6-route <text> rule <1-9999> time startdate <text>
```

Set date to start matching rule. Format for date: yyyy-mm-dd. To specify time of date with startdate, append ‘T’ to date followed by time in 24 hour notation hh:mm:ss. For eg startdate value of 2009-01-21T13:30:00 refers to 21st Jan 2009 with time 13:30:00.

```
set policy ipv6-route <text> rule <1-9999> time starttime <text>
```

Set time of day to start matching rule. Format of time: hh:mm:ss using 24 hours notation.

```
set policy ipv6-route <text> rule <1-9999> time stopdate <text>
```

Set date to stop matching rule. Format for date: yyyy-mm-dd. To specify time of date with stopdate, append 'T' to date followed by time in 24 hour notation hh:mm:ss. For eg startdate value of 2009-01-21T13:30:00 refers to 21st Jan 2009 with time 13:30:00.

```
set policy ipv6-route <text> rule <1-9999> time stoptime <text>
```

Set time of day to stop matching rule. Format of time: hh:mm:ss using 24 hours notation.

```
set policy ipv6-route <text> rule <1-9999> time utc
```

Interpret times for startdate, stopdate, starttime and stoptime to be UTC.

```
set policy ipv6-route <text> rule <1-9999> time weekdays
```

Weekdays to match rule on. Format for weekdays: Mon,Thu,Sat. To negate add ! at the front eg. !Mon,Thu,Sat.

Route Map Policy

Route map is a powerfull command, that gives network administrators a very useful and flexible tool for traffic manipulation.

Configuration

Route Map

```
set policy route-map <text>
```

This command creates a new route-map policy, identified by <text>.

```
set policy route-map <text> description <text>
```

Set description for the route-map policy.

```
set policy route-map <text> rule <1-65535> action <permit|deny>
```

Set action for the route-map policy.

```
set policy route-map <text> rule <1-65535> call <text>
```

Call another route-map policy on match.

```
set policy route-map <text> rule <1-65535> continue <1-65535>
```

Jump to a different rule in this route-map on a match.

```
set policy route-map <text> rule <1-65535> description <text>
```

Set description for the rule in the route-map policy.

```
set policy route-map <text> rule <1-65535> match as-path <text>
```

BGP as-path list to match.

```
set policy route-map <text> rule <1-65535> match community community-list  
<text>
```

BGP community-list to match.

```
set policy route-map <text> rule <1-65535> match community exact-match
```

Set BGP community-list to exactly match.

```
set policy route-map <text> rule <1-65535> match extcommunity <text>
```

BGP extended community to match.

```
set policy route-map <text> rule <1-65535> match interface <text>
```

First hop interface of a route to match.

```
set policy route-map <text> rule <1-65535> match ip address access-list
<1-2699>
```

IP address of route to match, based on access-list.

```
set policy route-map <text> rule <1-65535> match ip address prefix-list <text>
```

IP address of route to match, based on prefix-list.

```
set policy route-map <text> rule <1-65535> match ip nexthop access-list
<1-2699>
```

IP next-hop of route to match, based on access-list.

```
set policy route-map <text> rule <1-65535> match ip nexthop prefix-list <text>
```

IP next-hop of route to match, based on prefix-list.

```
set policy route-map <text> rule <1-65535> match ip route-source access-list
<1-2699>
```

IP route source of route to match, based on access-list.

```
set policy route-map <text> rule <1-65535> match ip route-source prefix-list
<text>
```

IP route source of route to match, based on prefix-list.

```
set policy route-map <text> rule <1-65535> match ipv6 address access-list
<text>
```

IPv6 address of route to match, based on IPv6 access-list.

```
set policy route-map <text> rule <1-65535> match ipv6 address prefix-list
<text>
```

IPv6 address of route to match, based on IPv6 prefix-list.

```
set policy route-map <text> rule <1-65535> match ipv6 nexthop
<h:h:h:h:h:h:h:h>
```

Nexthop IPv6 address to match.

```
set policy route-map <text> rule <1-65535> match large-community
large-community-list <text>
```

Match BGP large communities.

```
set policy route-map <text> rule <1-65535> match local-preference
<0-4294967295>
```

Match local preference.

```
set policy route-map <text> rule <1-65535> match metric <1-65535>
```

Match route metric.

```
set policy route-map <text> rule <1-65535> match origin <egp|igp|incomplete>
```

Border Gateway Protocol (BGP) origin code to match.

```
set policy route-map <text> rule <1-65535> match peer <x.x.x.x>
```

Peer IP address to match.

```
set policy route-map <text> rule <1-65535> match rpki <invalid|notfound|valid>
```

Match RPKI validation result.

```
set policy route-map <text> rule <1-65535> match tag <1-65535>
```

Route tag to match.

```
set policy route-map <text> rule <1-65535> on-match goto <1-65535>
```

Exit policy on match: go to rule <1-65535>

```
set policy route-map <text> rule <1-65535> on-match next
```

Exit policy on match: go to next sequence number.

```
set policy route-map <text> rule <1-65535> set aggregator <as|ip>  
<1-4294967295|x.x.x.x>
```

BGP aggregator attribute: AS number or IP address of an aggregation.

```
set policy route-map <text> rule <1-65535> set as-path-exclude <text>
```

Remove ASN(s) from a BGP AS-path attribute. For example “456 64500 45001”.

```
set policy route-map <text> rule <1-65535> set as-path-prepend <text>
```

Prepend string for a BGP AS-path attribute. For example “64501 64501”.

```
set policy route-map <text> rule <1-65535> set atomic-aggregate
```

BGP atomic aggregate attribute.

```
set policy route-map <text> rule <1-65535> set bgp-extcommunity-rt <aa:nn>
```

Set route target value. ExtCommunity in format: asn:value.

```
set policy route-map <text> rule <1-65535> set comm-list comm-list <text>
```

BGP communities with a community-list.

```
set policy route-map <text> rule <1-65535> set comm-list delete
```

Delete BGP communities matching the community-list.

```
set policy route-map <text> rule <1-65535> set community <aa:bb|local-AS|no-advertise|no-ex
```

Set BGP community attribute.

```
set policy route-map <text> rule <1-65535> set distance <0-255>
```

Locally significant administrative distance.

```
set policy route-map <text> rule <1-65535> set extcommunity-rt <text>
```

Set route target value.

```
set policy route-map <text> rule <1-65535> set extcommunity-soo <text>
```

Set site of origin value.

```
set policy route-map <text> rule <1-65535> set ip-next-hop <x.x.x.x>
```

Nexthop IP address.

```
set policy route-map <text> rule <1-65535> set ipv6-next-hop <global|local>
<h:h:h:h:h:h:h:h>
```

Next hop IPv6 address.

```
set policy route-map <text> rule <1-65535> set large-community <text>
```

Set BGP large community value.

```
set policy route-map <text> rule <1-65535> set local-preference <0-4294967295>
```

Set BGP local preference attribute.

```
set policy route-map <text> rule <1-65535> set metric <+/-metric|0-4294967295>
```

Set destination routing protocol metric. Add or subtract metric, or set metric value.

```
set policy route-map <text> rule <1-65535> set metric-type <type-1|type-2>
```

Set OSPF external metric-type.

```
set policy route-map <text> rule <1-65535> set origin <igp|egp|incomplete>
```

Set BGP origin code.

```
set policy route-map <text> rule <1-65535> set originator-id <x.x.x.x>
```

Set BGP originator ID attribute.

```
set policy route-map <text> rule <1-65535> set src <x.x.x.x|h:h:h:h:h:h:h:h>
```

Set source IP/IPv6 address for route.

```
set policy route-map <text> rule <1-65535> set table <1-200>
```

Set prefixes to table.

```
set policy route-map <text> rule <1-65535> set tag <1-65535>
```

Set tag value for routing protocol.

```
set policy route-map <text> rule <1-65535> set weight <0-4294967295>
```

Set BGP weight attribute

Local Route Policy

Policies for local traffic are defined in this section.

Configuration

Local Route

```
set policy local-route rule <1-32765> set table <1-200|main>
```

Set routing table to forward packet to.

```
set policy local-route rule <1-32765> source <x.x.x.x|x.x.x.x/x>
```

Set source address or prefix to match.

BGP - AS Path Policy

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **as-path-list** is one of them.

Configuration

policy as-path-list

```
set policy as-path-list <text>
```

Create as-path-policy identified by name <text>.

```
set policy as-path-list <text> description <text>
```

Set description for as-path-list policy.

```
set policy as-path-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy as-path-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy as-path-list <text> rule <1-65535> regex <text>
```

Regular expression to match against an AS path. For example “64501 64502”.

BGP - Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **community-list** is one of them.

Configuration

policy community-list

```
set policy community-list <text>
```

Creat community-list policy identified by name <text>.

```
set policy community-list <text> description <text>
```

Set description for community-list policy.

```
set policy community-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy community-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy community-list <text> rule <1-65535> regex <aa:nn|local-AS|no-advertise|no-export>
```

Regular expression to match against a community-list.

BGP - Extended Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **extcommunity-list** is one of them.

Configuration

policy extcommunity-list

```
set policy extcommunity-list <text>
```

Creat extcommunity-list policy identified by name <text>.

```
set policy extcommunity-list <text> description <text>
```

Set description for extcommunity-list policy.

```
set policy extcommunity-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy extcommunity-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy extcommunity-list <text> rule <1-65535> regex <text>
```

Regular expression to match against an extended community list, where text could be:

- <aa:nn:nn>: Extended community list regular expression.
- <rt aa:nn:nn>: Route Target regular expression.
- <soo aa:nn:nn>: Site of Origin regular expression.

BGP - Large Community List

VyOS provides policies commands exclusively for BGP traffic filtering and manipulation: **large-community-list** is one of them.

Configuration

policy large-community-list

```
set policy large-community-list <text>
```

Creat large-community-list policy identified by name <text>.

```
set policy large-community-list <text> description <text>
```

Set description for large-community-list policy.

```
set policy large-community-list <text> rule <1-65535> action <permit|deny>
```

Set action to take on entries matching this rule.

```
set policy large-community-list <text> rule <1-65535> description <text>
```

Set description for rule.

```
set policy large-community-list <text> rule <1-65535> regex <aa:nn:nn>
```

Regular expression to match against a large community list.

8.7.2 Examples

Examples of policies usage:

BGP Example

Policy definition:

```
# Create policy
set policy route-map setmet rule 2 action 'permit'
set policy route-map setmet rule 2 set as-path-prepend '2 2 2'

# Apply policy to BGP
set protocols bgp local-as 1
set protocols bgp neighbor 203.0.113.2 address-family ipv4-unicast route-map import
↪ 'setmet'
set protocols bgp neighbor 203.0.113.2 address-family ipv4-unicast soft-
↪ reconfiguration 'inbound'
```

Using ‘soft-reconfiguration’ we get the policy update without bouncing the neighbor.

Routes learned before routing policy applied:

```
vyos@vos1:~$ show ip bgp
BGP table version is 0, local router ID is 192.168.56.101
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale, R Removed
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop              Metric LocPrf Weight Path
*> 198.51.100.3/32   203.0.113.2                1              0 2 i  < Path

Total number of prefixes 1
```

Routes learned after routing policy applied:

```
vyos@vos1:~$ show ip bgp
BGP table version is 0, local router ID is 192.168.56.101
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
               r RIB-failure, S Stale, R Removed
Origin codes: i - IGP, e - EGP, ? - incomplete

   Network          Next Hop              Metric LocPrf Weight Path
*> 198.51.100.3/32   203.0.113.2                1              0 2 2 2 2 i

Total number of prefixes 1
vyos@vos1:~$
```

You now see the longer AS path.

Transparent Proxy

The following example will show how VyOS can be used to redirect web traffic to an external transparent proxy:

```
set policy route FILTER-WEB rule 1000 destination port 80
set policy route FILTER-WEB rule 1000 protocol tcp
set policy route FILTER-WEB rule 1000 set table 100
```

This creates a route policy called **FILTER-WEB** with one rule to set the routing table for matching traffic (TCP port 80) to table ID 100 instead of the default routing table.

To create routing table 100 and add a new default gateway to be used by traffic matching our route policy:

```
set protocols static table 100 route 0.0.0.0/0 next-hop 10.255.0.2
```

This can be confirmed using the `show ip route table 100 operational` command.

Finally, to apply the policy route to ingress traffic on our LAN interface, we use:

```
set interfaces ethernet eth1 policy route FILTER-WEB
```

Multiple Uplinks

VyOS Policy-Based Routing (PBR) works by matching source IP address ranges and forwarding the traffic using different routing tables.

Routing tables that will be used in this example are:

- `table 10` Routing table used for VLAN 10 (192.168.188.0/24)
- `table 11` Routing table used for VLAN 11 (192.168.189.0/24)
- `main` Routing table used by VyOS and other interfaces not participating in PBR

Add default routes for routing table 10 and table 11

```
set protocols static table 10 route 0.0.0.0/0 next-hop 192.0.2.1
set protocols static table 11 route 0.0.0.0/0 next-hop 192.0.2.2
```

Add policy route matching VLAN source addresses

```
set policy route PBR rule 20 set table '10'
set policy route PBR rule 20 description 'Route VLAN10 traffic to table 10'
set policy route PBR rule 20 source address '192.168.188.0/24'

set policy route PBR rule 30 set table '11'
set policy route PBR rule 30 description 'Route VLAN11 traffic to table 11'
set policy route PBR rule 30 source address '192.168.189.0/24'
```

Apply routing policy to **inbound** direction of out VLAN interfaces

```
set interfaces ethernet eth0 vif 10 policy route 'PBR'
set interfaces ethernet eth0 vif 11 policy route 'PBR'
```

OPTIONAL: Exclude Inter-VLAN traffic (between VLAN10 and VLAN11) from PBR

```
set policy route PBR rule 10 description 'VLAN10 <-> VLAN11 shortcut'
set policy route PBR rule 10 destination address '192.168.188.0/24'
set policy route PBR rule 10 destination address '192.168.189.0/24'
set policy route PBR rule 10 set table 'main'
```

These commands allow the VLAN10 and VLAN20 hosts to communicate with each other using the main routing table.

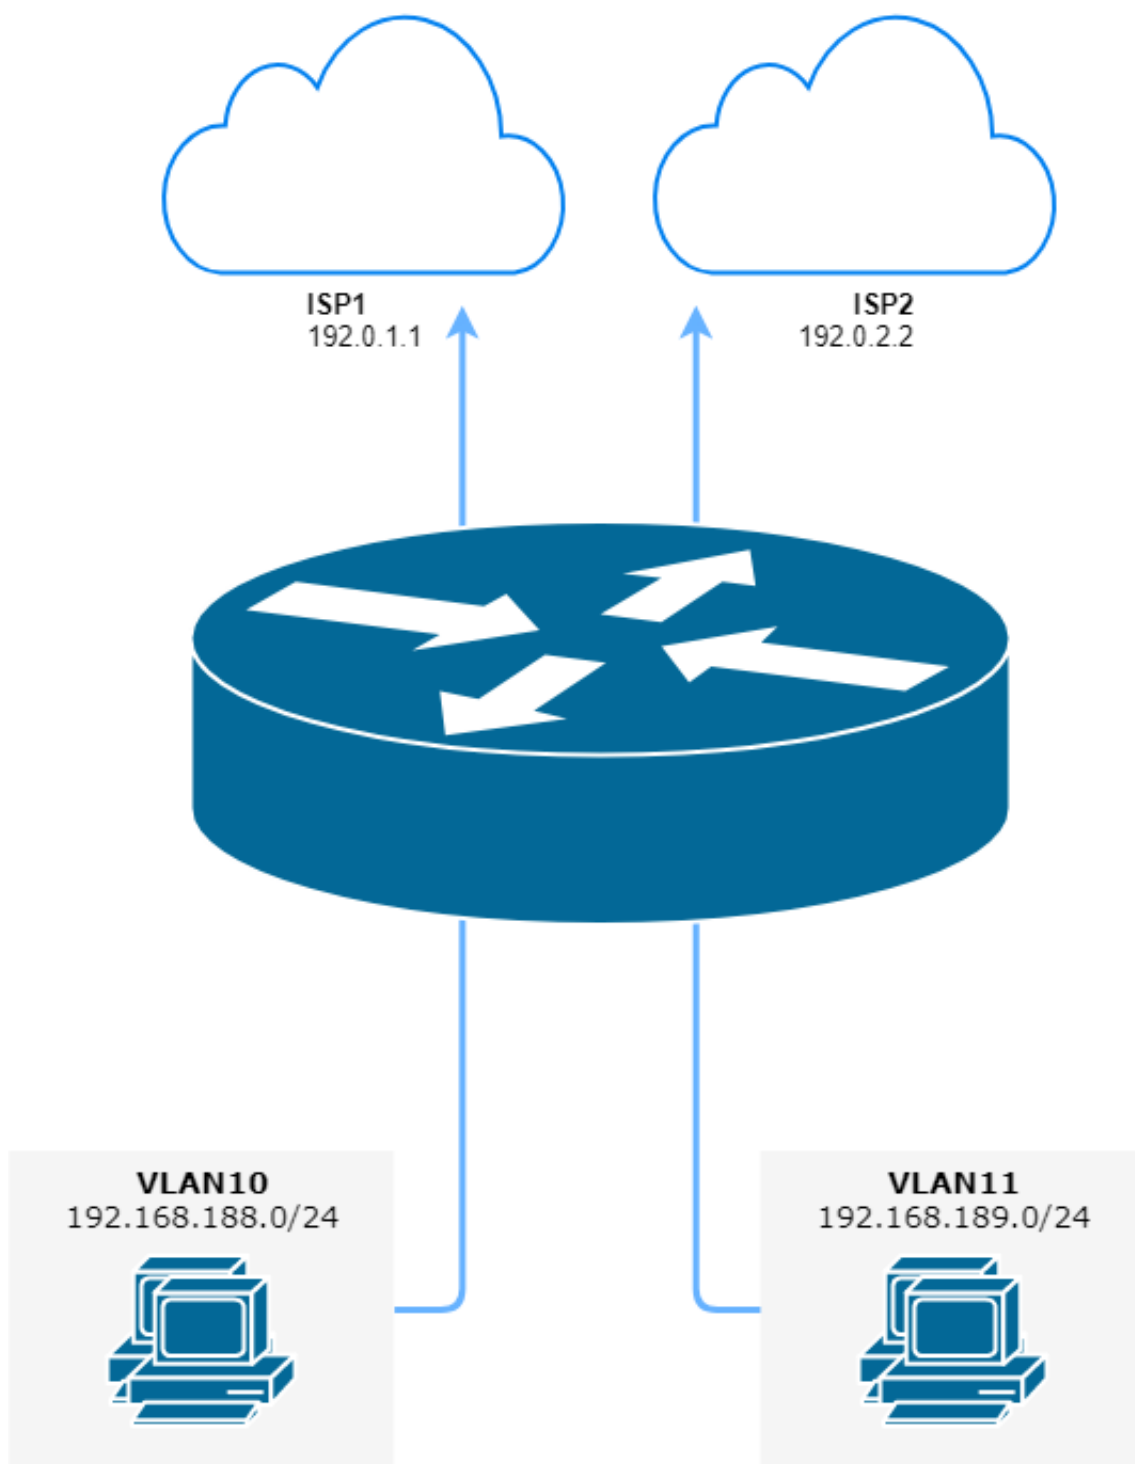

Fig. 2: Policy-Based Routing with multiple ISP uplinks (source `./draw.io/pbr_example_1.drawio`)

Local route

The following example allows VyOS to use PBR (Policy-Based Routing) for traffic, which originated from the router itself. That solution for multiple ISP's and VyOS router will respond from the same interface that the packet was received. Also, it used, if we want that one VPN tunnel to be through one provider, and the second through another.

- 203.0.113.254 IP address on VyOS eth1 from ISP1
- 192.168.2.254 IP address on VyOS eth2 from ISP2
- table 10 Routing table used for ISP1
- table 11 Routing table used for ISP2

```
set policy local-route rule 101 set table '10'
set policy local-route rule 101 source '203.0.113.254'
set policy local-route rule 102 set table '11'
set policy local-route rule 102 source '192.0.2.254'
set protocols static table 10 route 0.0.0.0/0 next-hop '203.0.113.1'
set protocols static table 11 route 0.0.0.0/0 next-hop '192.0.2.2'
```

Add multiple source IP in one rule with same priority

```
set policy local-route rule 101 set table '10'
set policy local-route rule 101 source '203.0.113.254'
set policy local-route rule 101 source '203.0.113.253'
set policy local-route rule 101 source '198.51.100.0/24'
```

8.8 PKI

VyOS 1.4 changed the way in how encryptions keys/certificates are stored on the running system. In the pre VyOS 1.4 era, certificates got stored under /config and every service referenced a file. That made copying a running configuration from system A to system B a bit harder, as you had to copy the files and their permissions by hand.

VyOS 1.4 comes with a new approach where the keys are stored on the CLI and are simply referenced by their name.

Don't be afraid that you need to re-do your configuration. Key transformation is handled, as always, by our migration scripts, so this will be a smooth transition for you!

8.8.1 Key Generation

Certificate Authority (CA)

VyOS now also has the ability to create CAs, keys, Diffie-Hellman and other keypairs from an easy to access operational level command.

generate pki ca

Create a new CA and output the CAs public and private key on the console.

generate pki ca install <name>

Create a new CA and output the CAs public and private key on the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`name` is used for the VyOS CLI command to identify this key. This key `name` is then used in the CLI configuration to reference the key instance.

generate pki ca sign <ca-name>

Create a new subordinate CA and sign it using the private key referenced by *ca-name*.

generate pki ca sign <name> install

Create a new subordinate CA and sign it using the private key referenced by *name*.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`name` is used for the VyOS CLI command to identify this key. This key `name` is then used in the CLI configuration to reference the key instance.

Certificates

generate pki certificate

Create a new public/private keypair and output the certificate on the console.

generate pki certificate install <name>

Create a new public/private keypair and output the certificate on the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`name` is used for the VyOS CLI command to identify this key. This key `name` is then used in the CLI configuration to reference the key instance.

generate pki certificate self-signed

Create a new self-signed certificate. The public/private is then shown on the console.

generate pki certificate self-signed install <name>

Create a new self-signed certificate. The public/private is then shown on the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`name` is used for the VyOS CLI command to identify this key. This key `name` is then used in the CLI configuration to reference the key instance.

generate pki certificate sign <ca-name>

Create a new public/private keypair which is signed by the CA referenced by *ca-name*. The signed certificate is then output to the console.

generate pki certificate sign <ca-name> install <name>

Create a new public/private keypair which is signed by the CA referenced by *ca-name*. The signed certificate is then output to the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

Diffie-Hellman parameters

generate pki dh

Generate a new set of DH (Diffie-Hellman) parameters. The key size is requested by the CLI and defaults to 2048 bit.

The generated parameters are then output to the console.

generate pki dh install <name>

Generate a new set of DH parameters. The key size is requested by the CLI and defaults to 2048 bit.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

OpenVPN

generate pki openvpn shared-secret

Generate a new OpenVPN shared secret. The generated secret is the output to the console.

generate pki openvpn shared-secret install <name>

Generate a new OpenVPN shared secret. The generated secret is the output to the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

name is used for the VyOS CLI command to identify this key. This key name is then used in the CLI configuration to reference the key instance.

WireGuard

generate pki wireguard key-pair

Generate a new WireGuard public/private key portion and output the result to the console.

generate pki wireguard key-pair install <interface>

Generate a new WireGuard public/private key portion and output the result to the console.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`interface` is used for the VyOS CLI command to identify the WireGuard interface where this private key is to be used.

generate pki wireguard pre-shared-key

Generate a WireGuard pre-shared secret used for peers to communicate.

generate pki wireguard pre-shared-key install <peer>

Generate a WireGuard pre-shared secret used for peers to communicate.

Note: In addition to the command above, the output is in a format which can be used to directly import the key into the VyOS CLI by simply copy-pasting the output from op-mode into configuration mode.

`peer` is used for the VyOS CLI command to identify the WireGuard peer where this secret is to be used.

8.8.2 Configuration

8.8.3 Operation

VyOS operational mode commands are not only available for generating keys but also to display them.

show pki ca

Show a list of installed CA certificates.

```
vyos@vyos:~$ show pki ca
Certificate Authorities:

8.9 Protocols

8.9.1 BFD

BFD (Bidirectional Forwarding Detection) is described and extended by the following RFCs: [RFC 5880](#), [RFC 5881](#) and [RFC 5883](#).

In the age of very fast networks, a second of unreachability may equal millions of lost packets. The idea behind BFD is to detect very quickly when a peer is down and take action extremely fast.

BFD sends lots of small UDP packets very quickly to ensures that the peer is still alive.

This allows avoiding the timers defined in BGP and OSPF protocol to expires.

Configure BFD

```
set protocols bfd peer <address>
```

Set BFD peer IPv4 address or IPv6 address

```
set protocols bfd peer <address> echo-mode
```

Enables the echo transmission mode

```
set protocols bfd peer <address> multihop
```

Allow this BFD peer to not be directly connected

```
set protocols bfd peer <address> source [address <address> | interface <interface>]
```

Bind listener to specifid interface/address, mandatory for IPv6

```
set protocols bfd peer <address> interval echo-interval <10-60000>
```

The minimal echo receive transmission interval that this system is capable of handling

```
set protocols bfd peer <address> interval multiplier <2-255>
```

Remote transmission interval will be multiplied by this value

```
set protocols bfd peer <address> interval [receive | transmit] <10-60000>
```

Interval in milliseconds

```
set protocols bfd peer <address> shutdown
```

Disable a BFD peer

Enable BFD in BGP

```
set protocols bgp neighbor <neighbor> bfd
```

Enable BFD on a single BGP neighbor

```
set protocols bgp peer-group <neighbor> bfd
```

Enable BFD on a BGP peer group

Enable BFD in OSPF

```
set interfaces ethernet <interface> ip ospf bfd
```

Enable BFD for OSPF on a interface

```
set interfaces ethernet <interface> ipv6 ospfv3 bfd
```

Enable BFD for OSPFv3 on a interface

Enable BFD in ISIS

```
set protocols isis <name> interface <interface> bfd
```

Enable BFD for ISIS on a interface

Operational Commands

```
show protocols bfd peer
```

Show all BFD peers

```
BFD Peers:
  peer 198.51.100.33 vrf default interface eth4.100
    ID: 4182341893
    Remote ID: 12678929647
    Status: up
    Uptime: 1 month(s), 16 hour(s), 29 minute(s), 38 second(s)
    Diagnostics: ok
    Remote diagnostics: ok
    Local timers:
      Receive interval: 300ms
      Transmission interval: 300ms

    ID: 4618932327
    Remote ID: 3312345688
    Status: up
    Uptime: 20 hour(s), 16 minute(s), 19 second(s)
    Diagnostics: ok
    Remote diagnostics: ok
    Local timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 50ms
    Remote timers:
      Receive interval: 300ms
      Transmission interval: 300ms
      Echo transmission interval: 0ms
```

8.9.2 BGP

BGP (Border Gateway Protocol) is one of the Exterior Gateway Protocols and the de facto standard interdomain routing protocol. The latest BGP version is 4. BGP-4 is described in [RFC 1771](#) and updated by [RFC 4271](#). [RFC 2858](#) adds multiprotocol support to BGP.

VyOS makes use of FRR (Free Range Routing) and we would like to thank them for their effort!

Basic Concepts

Autonomous Systems

From [RFC 1930](#):

An AS is a connected group of one or more IP prefixes run by one or more network operators which has a SINGLE and CLEARLY DEFINED routing policy.

Each AS (Autonomous System) has an identifying number associated with it called an ASN (Autonomous System Number). This is a two octet value ranging in value from 1 to 65535. The AS numbers 64512 through 65535 are defined as private AS numbers. Private AS numbers must not be advertised on the global Internet. The 2-byte AS number range has been exhausted. 4-byte AS numbers are specified in [RFC 6793](#), and provide a pool of 4294967296 AS numbers.

The ASN is one of the essential elements of BGP. BGP is a distance vector routing protocol, and the AS-Path framework provides distance vector metric and loop detection to BGP.

```
set protocols bgp local-as <asn>
```

Set local ASN that this router represents. This is a mandatory option!

Address Families

Multiprotocol extensions enable BGP to carry routing information for multiple network layer protocols. BGP supports an Address Family Identifier (AFI) for IPv4 and IPv6.

Route Selection

The route selection process used by FRR's BGP implementation uses the following decision criterion, starting at the top of the list and going towards the bottom until one of the factors can be used.

1. **Weight check**

Prefer higher local weight routes to lower routes.

2. **Local preference check**

Prefer higher local preference routes to lower.

3. **Local route check**

Prefer local routes (statics, aggregates, redistributed) to received routes.

4. **AS path length check**

Prefer shortest hop-count AS_PATHs.

5. **Origin check**

Prefer the lowest origin type route. That is, prefer IGP origin routes to EGP, to Incomplete routes.

6. MED check

Where routes with a MED were received from the same AS, prefer the route with the lowest MED.

7. External check

Prefer the route received from an external, eBGP peer over routes received from other types of peers.

8. IGP cost check

Prefer the route with the lower IGP cost.

9. Multi-path check

If multi-pathing is enabled, then check whether the routes not yet distinguished in preference may be considered equal. If `bgp bestpath as-path multipath-relax` is set, all such routes are considered equal, otherwise routes received via iBGP with identical AS_PATHs or routes received from eBGP neighbours in the same AS are considered equal.

10. Already-selected external check

Where both routes were received from eBGP peers, then prefer the route which is already selected. Note that this check is not applied if `bgp bestpath compare-routerid` is configured. This check can prevent some cases of oscillation.

11. Router-ID check

Prefer the route with the lowest *router-ID*. If the route has an *ORIGINATOR_ID* attribute, through iBGP reflection, then that router ID is used, otherwise the *router-ID* of the peer the route was received from is used.

12. Cluster-List length check

The route with the shortest cluster-list length is used. The cluster-list reflects the iBGP reflection path the route has taken.

13. Peer address

Prefer the route received from the peer with the higher transport layer address, as a last-resort tie-breaker.

Capability Negotiation

When adding IPv6 routing information exchange feature to BGP. There were some proposals. IETF (Internet Engineering Task Force) IDR (Inter Domain Routing) adopted a proposal called Multiprotocol Extension for BGP. The specification is described in [RFC 2283](#). The protocol does not define new protocols. It defines new attributes to existing BGP. When it is used exchanging IPv6 routing information it is called BGP-4+. When it is used for exchanging multicast routing information it is called MBGP.

bgpd supports Multiprotocol Extension for BGP. So if a remote peer supports the protocol, *bgpd* can exchange IPv6 and/or multicast routing information.

Traditional BGP did not have the feature to detect a remote peer's capabilities, e.g. whether it can handle prefix types other than IPv4 unicast routes. This was a big problem using Multiprotocol Extension for BGP in an operational network. [RFC 2842](#) adopted a feature called Capability Negotiation. *bgpd* use this Capability Negotiation to detect the remote peer's capabilities. If a peer is only configured as an IPv4 unicast neighbor, *bgpd* does not send these Capability Negotiation packets (at least not unless other optional BGP features require capability negotiation).

By default, FRR will bring up peering with minimal common capability for the both sides. For example, if the local router has unicast and multicast capabilities and the remote router only has unicast capability the local router will establish the connection with unicast only capability. When there are no common capabilities, FRR sends Unsupported Capability error and then resets the connection.

Configuration

BGP Router Configuration

First of all you must configure BGP router with the ASN. The AS number is an identifier for the autonomous system. The BGP protocol uses the AS number for detecting whether the BGP connection is internal or external. VyOS does not have a special command to start the BGP process. The BGP process starts when the first neighbor is configured.

```
set protocols bgp local-as <asn>
```

Set local autonomous system number that this router represents. This is a mandatory option!

Peers Configuration

Defining Peers

```
set protocols bgp neighbor <address|interface> remote-as <nasn>
```

This command creates a new neighbor whose remote-as is <nasn>. The neighbor address can be an IPv4 address or an IPv6 address or an interface to use for the connection. The command is applicable for peer and peer group.

```
set protocols bgp neighbor <address|interface> remote-as internal
```

Create a peer as you would when you specify an ASN, except that if the peers ASN is different than mine as specified under the `protocols bgp <asn>` command the connection will be denied.

```
set protocols bgp neighbor <address|interface> remote-as external
```

Create a peer as you would when you specify an ASN, except that if the peers ASN is the same as mine as specified under the `protocols bgp <asn>` command the connection will be denied.

```
set protocols bgp neighbor <address|interface> shutdown
```

This command disable the peer or peer group. To reenale the peer use the delete form of this command.

```
set protocols bgp neighbor <address|interface> description <text>
```

Set description of the peer or peer group.

```
set protocols bgp neighbor <address|interface> update-source  
<address|interface>
```

Specify the IPv4 source address to use for the BGP session to this neighbor, may be specified as either an IPv4 address directly or as an interface name.

Capability Negotiation

```
set protocols bgp neighbor <address|interface> capability dynamic
```

This command would allow the dynamic update of capabilities over an established BGP session.

```
set protocols bgp neighbor <address|interface> capability extended-nexthop
```

Allow bgp to negotiate the extended-nexthop capability with it's peer. If you are peering over a IPv6 Link-Local address then this capability is turned on automatically. If you are peering over a IPv6 Global Address then turning on this command will allow BGP to install IPv4 routes with IPv6 nexthops if you do not have IPv4 configured on interfaces.

```
set protocols bgp neighbor <address|interface> disable-capability-negotiation
```

Suppress sending Capability Negotiation as OPEN message optional parameter to the peer. This command only affects the peer is configured other than IPv4 unicast configuration.

When remote peer does not have capability negotiation feature, remote peer will not send any capabilities at all. In that case, bgp configures the peer with configured capabilities.

You may prefer locally configured capabilities more than the negotiated capabilities even though remote peer sends capabilities. If the peer is configured by `override-capability`, VyOS ignores received capabilities then override negotiated capabilities with configured values.

Additionally you should keep in mind that this feature fundamentally disables the ability to use widely deployed BGP features. BGP unnumbered, hostname support, AS4, Addpath, Route Refresh, ORF, Dynamic Capabilities, and graceful restart.

set protocols bgp neighbor <address|interface> override-capability

This command allow override the result of Capability Negotiation with local configuration. Ignore remote peer's capability value.

set protocols bgp neighbor <address|interface> strict-capability-match

This command forces strictly compare remote capabilities and local capabilities. If capabilities are different, send Unsupported Capability error then reset connection.

You may want to disable sending Capability Negotiation OPEN message optional parameter to the peer when remote peer does not implement Capability Negotiation. Please use `disable-capability-negotiation` command to disable the feature.

Peer Parameters

**set protocols bgp neighbor <address|interface> address-family
<ipv4-unicast|ipv6-unicast> allowas-in number <number>**

This command accept incoming routes with AS path containing AS number with the same value as the current system AS. This is used when you want to use the same AS number in your sites, but you can't connect them directly.

The number parameter (1-10) configures the amount of accepted occurrences of the system AS number in AS path.

This command is only allowed for eBGP peers. It is not applicable for peer groups.

**set protocols bgp neighbor <address|interface> address-family
<ipv4-unicast|ipv6-unicast> as-override**

This command override AS number of the originating router with the local AS number.

Usually this configuration is used in PEs (Provider Edge) to replace the incoming customer AS number so the connected CE (Customer Edge) can use the same AS number as the other customer sites. This allows customers of the provider network to use the same AS number across their sites.

This command is only allowed for eBGP peers.

**set protocols bgp neighbor <address|interface> address-family
<ipv4-unicast|ipv6-unicast> attribute-unchanged <as-path|med|next-hop>**

This command specifies attributes to be left unchanged for advertisements sent to a peer or peer group.

**set protocols bgp neighbor <address|interface> address-family
<ipv4-unicast|ipv6-unicast> maximum-prefix <number>**

This command specifies a maximum number of prefixes we can receive from a given peer. If this number is exceeded, the BGP session will be destroyed. The number range is 1 to 4294967295.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> nexthop-self
```

This command forces the BGP speaker to report itself as the next hop for an advertised route it advertised to a neighbor.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> remove-private-as
```

This command removes the private ASN of routes that are advertised to the configured peer. It removes only private ASNs on routes advertised to EBGp peers.

If the AS-Path for the route has only private ASNs, the private ASNs are removed.

If the AS-Path for the route has a private ASN between public ASNs, it is assumed that this is a design choice, and the private ASN is not removed.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> soft-reconfiguration inbound
```

Changes in BGP policies require the BGP session to be cleared. Clearing has a large negative impact on network operations. Soft reconfiguration enables you to generate inbound updates from a neighbor, change and activate BGP policies without clearing the BGP session.

This command specifies that route updates received from this neighbor will be stored unmodified, regardless of the inbound policy. When inbound soft reconfiguration is enabled, the stored updates are processed by the new policy configuration to create new inbound updates.

Note: Storage of route updates uses memory. If you enable soft reconfiguration inbound for multiple neighbors, the amount of memory used can become significant.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> weight <number>
```

This command specifies a default weight value for the neighbor's routes. The number range is 1 to 65535.

```
set protocols bgp neighbor <address|interface> advertisement-interval  
<seconds>
```

This command specifies the minimum route advertisement interval for the peer. The interval value is 0 to 600 seconds, with the default advertisement interval being 0.

```
set protocols bgp neighbor <address|interface> disable-connected-check
```

This command allows peerings between directly connected eBGP peers using loopback addresses without adjusting the default TTL of 1.

```
set protocols bgp neighbor <address|interface> disable-send-community  
<extended|standard>
```

This command specifies that the community attribute should not be sent in route updates to a peer. By default community attribute is sent.

```
set protocols bgp neighbor <address|interface> ebgp-multihop <number>
```

This command allows sessions to be established with eBGP neighbors when they are multiple hops away. When the neighbor is not directly connected and this knob is not enabled, the session will not establish. The number of hops range is 1 to 255. This command is mutually exclusive with `ttl-security hops`.

```
set protocols bgp neighbor <address|interface> local-as <asn> [no-prepend]
[replace-as]
```

Specify an alternate AS for this BGP process when interacting with the specified peer or peer group. With no modifiers, the specified local-as is prepended to the received AS_PATH when receiving routing updates from the peer, and prepended to the outgoing AS_PATH (after the process local AS) when transmitting local routes to the peer.

If the `no-prepend` attribute is specified, then the supplied local-as is not prepended to the received AS_PATH.

If the `replace-as` attribute is specified, then only the supplied local-as is prepended to the AS_PATH when transmitting local-route updates to this peer.

Note: This command is only allowed for eBGP peers.

```
set protocols bgp neighbor <address|interface> passive
```

Configures the BGP speaker so that it only accepts inbound connections from, but does not initiate outbound connections to the peer or peer group.

```
set protocols bgp neighbor <address|interface> password <text>
```

This command specifies a MD5 password to be used with the tcp socket that is being used to connect to the remote peer.

```
set protocols bgp neighbor <address|interface> ttl-security hops <number>
```

This command enforces Generalized TTL Security Mechanism (GTSM), as specified in [RFC 5082](#). With this command, only neighbors that are the specified number of hops away will be allowed to become neighbors. The number of hops range is 1 to 254. This command is mutually exclusive with `ebgp-multihop`.

Peer Groups

Peer groups are used to help improve scaling by generating the same update information to all members of a peer group. Note that this means that the routes generated by a member of a peer group will be sent back to that originating peer with the originator identifier attribute set to indicated the originating peer. All peers not associated with a specific peer group are treated as belonging to a default peer group, and will share updates.

```
set protocols bgp peer-group <name>
```

This command defines a new peer group. You can specify to the group the same parameters that you can specify for specific neighbors.

Note: If you apply a parameter to an individual neighbor IP address, you override the action defined for a peer group that includes that IP address.

```
set protocols bgp neighbor <address|interface> peer-group <name>
```

This command bind specific peer to peer group with a given name.

Network Advertisement Configuration

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> network <prefix>
```

This command is used for advertising IPv4 or IPv6 networks.

Note: By default, the BGP prefix is advertised even if it's not present in the routing table. This behaviour differs from the implementation of some vendors.

set protocols bgp parameters network-import-check

This configuration modifies the behavior of the network statement. If you have this configured the underlying network must exist in the routing table.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> default-originate [route-map <name>]
```

By default, VyOS does not advertise a default route (0.0.0.0/0) even if it is in routing table. When you want to announce default routes to the peer, use this command. Using optional argument `route-map` you can inject the default route to given neighbor only if the conditions in the route map are met.

Route Aggregation Configuration

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address  
<prefix>
```

This command specifies an aggregate address. The router will also announce longer-prefixes inside of the aggregate address.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address  
<prefix> as-set
```

This command specifies an aggregate address with a mathematical set of autonomous systems. This command summarizes the AS_PATH attributes of all the individual routes.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> aggregate-address  
<prefix> summary-only
```

This command specifies an aggregate address and provides that longer-prefixes inside of the aggregate address are suppressed before sending BGP updates out to peers.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> unsuppress-map <name>
```

This command applies route-map to selectively unsuppress prefixes suppressed by summarisation.

Redistribution Configuration

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute  
<route source>
```

This command redistributes routing information from the given route source to the BGP process. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute  
<route source> metric <number>
```

This command specifies metric (MED) for redistributed routes. The metric range is 0 to 4294967295. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

```
set protocols bgp address-family <ipv4-unicast|ipv6-unicast> redistribute  
<route source> route-map <name>
```

This command allows to use route map to filter redistributed routes. There are six modes available for route source: connected, kernel, ospf, rip, static, table.

General Configuration

Common parameters

set protocols bgp parameters router-id <id>

This command specifies the router-ID. If router ID is not specified it will use the highest interface IP address.

set protocols bgp maximum-paths <ebgp|ibgp> <number>

This command defines the maximum number of parallel routes that the BGP can support. In order for BGP to use the second path, the following attributes have to match: Weight, Local Preference, AS Path (both AS number and AS path length), Origin code, MED, IGP metric. Also, the next hop address for each path must be different.

set protocols bgp parameters default no-ipv4-unicast

This command allows the user to specify that IPv4 peering is turned off by default.

set protocols bgp parameters log-neighbor-changes

This command enable logging neighbor up/down changes and reset reason.

set protocols bgp parameters no-client-to-client-reflection

This command disables route reflection between route reflector clients. By default, the clients of a route reflector are not required to be fully meshed and the routes from a client are reflected to other clients. However, if the clients are fully meshed, route reflection is not required. In this case, use the `no-client-to-client-reflection` command to disable client-to-client reflection.

set protocols bgp parameters no-fast-external-failover

Disable immediate session reset if peer's connected link goes down.

set protocols bgp listen range <prefix> peer-group <name>

This command is useful if one desires to loosen the requirement for BGP to have strictly defined neighbors. Specifically what is allowed is for the local router to listen to a range of IPv4 or IPv6 addresses defined by a prefix and to accept BGP open messages. When a TCP connection (and subsequently a BGP open message) from within this range tries to connect the local router then the local router will respond and connect with the parameters that are defined within the peer group. One must define a peer-group for each range that is listed. If no peer-group is defined then an error will keep you from committing the configuration.

set protocols bgp listen limit <number>

This command goes hand in hand with the listen range command to limit the amount of BGP neighbors that are allowed to connect to the local router. The limit range is 1 to 5000.

set protocols bgp parameters ebgp-requires-policy

This command changes the eBGP behavior of FRR. By default FRR enables [RFC 8212](#) functionality which affects how eBGP routes are advertised, namely no routes are advertised across eBGP sessions without some sort of egress route-map/policy in place. In VyOS however we have this RFC functionality disabled by default so that we can preserve backwards compatibility with older versions of VyOS. With this option one can enable [RFC 8212](#) functionality to operate.

Administrative Distance

```
set protocols bgp parameters distance global <external|internal|local>
<distance>
```

This command change distance value of BGP. The arguments are the distance values for external routes, internal routes and local routes respectively. The distance range is 1 to 255.

```
set protocols bgp parameters distance prefix <subnet> distance <distance>
```

This command sets the administrative distance for a particular route. The distance range is 1 to 255.

Note: Routes with a distance of 255 are effectively disabled and not installed into the kernel.

Timers

```
set protocols bgp timers holdtime <seconds>
```

This command specifies hold-time in seconds. The timer range is 4 to 65535. The default value is 180 second. If you set value to 0 VyOS will not hold routes.

```
set protocols bgp timers keepalive <seconds>
```

This command specifies keep-alive time in seconds. The timer can range from 4 to 65535. The default value is 60 second.

Route Dampening

When a route fails, a routing update is sent to withdraw the route from the network's routing tables. When the route is re-enabled, the change in availability is also advertised. A route that continually fails and returns requires a great deal of network traffic to update the network about the route's status.

Route dampening which described in [RFC 2439](#) enables you to identify routes that repeatedly fail and return. If route dampening is enabled, an unstable route accumulates penalties each time the route fails and returns. If the accumulated penalties exceed a threshold, the route is no longer advertised. This is route suppression. Routes that have been suppressed are re-entered into the routing table only when the amount of their penalty falls below a threshold.

A penalty of 1000 is assessed each time the route fails. When the penalties reach a predefined threshold (suppress-value), the router stops advertising the route.

Once a route is assessed a penalty, the penalty is decreased by half each time a predefined amount of time elapses (half-life-time). When the accumulated penalties fall below a predefined threshold (reuse-value), the route is unsuppressed and added back into the BGP routing table.

No route is suppressed indefinitely. Maximum-suppress-time defines the maximum time a route can be suppressed before it is re-advertised.

```
set protocols bgp parameters dampening half-life <minutes>
```

This command defines the amount of time in minutes after which a penalty is reduced by half. The timer range is 10 to 45 minutes.

```
set protocols bgp parameters dampening re-use <seconds>
```

This command defines the accumulated penalty amount at which the route is re-advertised. The penalty range is 1 to 20000.

```
set protocols bgp parameters dampening start-suppress-time <seconds>
```

This command defines the accumulated penalty amount at which the route is suppressed. The penalty range is 1 to 20000.

set protocols bgp parameters dampening max-suppress-time <seconds>

This command defines the maximum time in minutes that a route is suppressed. The timer range is 1 to 255 minutes.

Route Selection Configuration

set protocols bgp parameters always-compare-med

This command provides to compare the MED on routes, even when they were received from different neighbouring ASes. Setting this option makes the order of preference of routes more defined, and should eliminate MED induced oscillations.

set protocols bgp parameters bestpath as-path confed

This command specifies that the length of confederation path sets and sequences should be taken into account during the BGP best path decision process.

set protocols bgp parameters bestpath as-path multipath-relax

This command specifies that BGP decision process should consider paths of equal AS_PATH length candidates for multipath computation. Without the knob, the entire AS_PATH must match for multipath computation.

set protocols bgp parameters bestpath as-path ignore

Ignore AS_PATH length when selecting a route

set protocols bgp parameters bestpath compare-routerid

Ensure that when comparing routes where both are equal on most metrics, including local-pref, AS_PATH length, IGP cost, MED, that the tie is broken based on router-ID.

If this option is enabled, then the already-selected check, where already selected eBGP routes are preferred, is skipped.

If a route has an ORIGINATOR_ID attribute because it has been reflected, that ORIGINATOR_ID will be used. Otherwise, the router-ID of the peer the route was received from will be used.

The advantage of this is that the route-selection (at this point) will be more deterministic. The disadvantage is that a few or even one lowest-ID router may attract all traffic to otherwise-equal paths because of this check. It may increase the possibility of MED or IGP oscillation, unless other measures were taken to avoid these. The exact behaviour will be sensitive to the iBGP and reflection topology.

set protocols bgp parameters bestpath med confed

This command specifies that BGP considers the MED when comparing routes originated from different sub-ASs within the confederation to which this BGP speaker belongs. The default state, where the MED attribute is not considered.

set protocols bgp parameters bestpath med missing-as-worst

This command specifies that a route with a MED is always considered to be better than a route without a MED by causing the missing MED attribute to have a value of infinity. The default state, where the missing MED attribute is considered to have a value of zero.

set protocols bgp parameters default local-pref <local-pref value>

This command specifies the default local preference value. The local preference range is 0 to 4294967295.

set protocols bgp parameters deterministic-med

This command provides to compare different MED values that advertised by neighbours in the same AS for routes selection. When this command is enabled, routes from the same autonomous system are grouped together, and the best entries of each group are compared.

```
set protocols bgp address-family ipv4-unicast network <prefix> backdoor
```

This command allows the router to prefer route to specified prefix learned via IGP through backdoor link instead of a route to the same prefix learned via EBGp.

Route Filtering Configuration

In order to control and modify routing information that is exchanged between peers you can use route-map, filter-list, prefix-list, distribute-list.

For inbound updates the order of preference is:

- route-map
- filter-list
- prefix-list, distribute-list

For outbound updates the order of preference is:

- prefix-list, distribute-list
- filter-list
- route-map

Note: The attributes `prefix-list` and `distribute-list` are mutually exclusive, and only one command (`distribute-list` or `prefix-list`) can be applied to each inbound or outbound direction for a particular neighbor.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> distribute-list <export|import> <number>
```

This command applies the access list filters named in `<number>` to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the access list are applied.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> prefix-list <export|import> <name>
```

This command applies the prefix list filters named in `<name>` to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the prefix list are applied.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> route-map <export|import> <name>
```

This command applies the route map named in `<name>` to the specified BGP neighbor to control and modify routing information that is exchanged between peers. The arguments `export` and `import` specify the direction in which the route map are applied.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> filter-list <export|import> <name>
```

This command applies the AS path access list filters named in <name> to the specified BGP neighbor to restrict the routing information that BGP learns and/or advertises. The arguments `export` and `import` specify the direction in which the AS path access list are applied.

```
set protocols bgp neighbor <address|interface> address-family  
<ipv4-unicast|ipv6-unicast> capability orf <receive|send>
```

This command enables the ORF capability (described in [RFC 5291](#)) on the local router, and enables ORF capability advertisement to the specified BGP peer. The `receive` keyword configures a router to advertise ORF receive capabilities. The `send` keyword configures a router to advertise ORF send capabilities. To advertise a filter from a sender, you must create an IP prefix list for the specified BGP peer applied in inbound direction.

BGP Scaling Configuration

BGP routers connected inside the same AS through BGP belong to an internal BGP session, or IBGP. In order to prevent routing table loops, IBGP speaker does not advertise IBGP-learned routes to other IBGP speaker (Split Horizon mechanism). As such, IBGP requires a full mesh of all peers. For large networks, this quickly becomes unscalable.

There are two ways that help us to mitigate the BGP's full-mesh requirement in a network:

- Using BGP route-reflectors
- Using BGP confederation

Route Reflector Configuration

Introducing route reflectors removes the need for the full-mesh. When you configure a route reflector you have to tell the router whether the other IBGP router is a client or non-client. A client is an IBGP router that the route reflector will “reflect” routes to, the non-client is just a regular IBGP neighbor. Route reflectors mechanism is described in [RFC 4456](#) and updated by [RFC 7606](#).

```
set protocols bgp neighbor <address> address-family <ipv4-unicast|ipv6-unicast>  
route-reflector-client
```

This command specifies the given neighbor as route reflector client.

```
set protocols bgp parameters cluster-id <id>
```

This command specifies cluster ID which identifies a collection of route reflectors and their clients, and is used by route reflectors to avoid looping. By default cluster ID is set to the BGP router id value, but can be set to an arbitrary 32-bit value.

Confederation Configuration

A BGP confederation divides our AS into sub-ASes to reduce the number of required IBGP peerings. Within a sub-AS we still require full-mesh IBGP but between these sub-ASes we use something that looks like EBGp but behaves like IBGP (called confederation BGP). Confederation mechanism is described in [RFC 5065](#)

```
set protocols bgp parameters confederation identifier <asn>
```

This command specifies a BGP confederation identifier. <asn> is the number of the autonomous system that internally includes multiple sub-autonomous systems (a confederation).

```
set protocols bgp parameters confederation confederation peers <nsubasn>
```

This command sets other confederations <nsubasn> as members of autonomous system specified by confederation identifier <asn>.

Operational Mode Commands

Show

show <ip|ipv6> bgp

This command displays all entries in BGP routing table.

```
BGP table version is 10, local router ID is 10.0.35.3, vrf id 0
Default local pref 100, local AS 65000
Status codes:  s suppressed, d damped, h history, * valid, > best, = multipath,
                i internal, r RIB-failure, S Stale, R Removed
Nexthop codes: @NNN nexthop's vrf id, < announce-nh-self
Origin codes:  i - IGP, e - EGP, ? - incomplete

   Network          Next Hop             Metric LocPrf Weight Path
*> 198.51.100.0/24  10.0.34.4                 0           0 65004 i
*> 203.0.113.0/24   10.0.35.5                 0           0 65005 i

Displayed  2 routes and 2 total paths
```

show <ip|ipv6> bgp <address|prefix>

This command displays information about the particular entry in the BGP routing table.

```
BGP routing table entry for 198.51.100.0/24
Paths: (1 available, best #1, table default)
  Advertised to non peer-group peers:
    10.0.13.1 10.0.23.2 10.0.34.4 10.0.35.5
    65004
    10.0.34.4 from 10.0.34.4 (10.0.34.4)
      Origin IGP, metric 0, valid, external, best (First path received)
      Last update: Wed Jan  6 12:18:53 2021
```

show ip bgp cidr-only

This command displays routes with classless interdomain routing (CIDR).

show <ip|ipv6> bgp community <value>

This command displays routes that belong to specified BGP communities. Valid value is a community number in the range from 1 to 4294967200, or AA:NN (autonomous system-community number/2-byte number), no-export, local-as, or no-advertise.

show <ip|ipv6> bgp community-list <name>

This command displays routes that are permitted by the BGP community list.

show ip bgp dampened-paths

This command displays BGP dampened routes.

show ip bgp flap-statistics

This command displays information about flapping BGP routes.

show ip bgp filter-list <name>

This command displays BGP routes allowed by the specified AS Path access list.

show <ip|ipv6> bgp neighbors <address> advertised-routes

This command displays BGP routes advertised to a neighbor.

show <ip|ipv6> bgp neighbors <address> received-routes

This command displays BGP routes originating from the specified BGP neighbor before inbound policy is applied. To use this command inbound soft reconfiguration must be enabled.

show <ip|ipv6> bgp neighbors <address> routes

This command displays BGP received-routes that are accepted after filtering.

show <ip|ipv6> bgp neighbors <address> dampened-routes

This command displays dampened routes received from BGP neighbor.

show <ip|ipv6> bgp regexp <text>

This command displays information about BGP routes whose AS path matches the specified regular expression.

show <ip|ipv6> bgp summary

This command displays the status of all BGP connections.

```
IPv4 Unicast Summary:
BGP router identifier 10.0.35.3, local AS number 65000 vrf-id 0
BGP table version 11
RIB entries 5, using 920 bytes of memory
Peers 4, using 82 KiB of memory
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
10.0.13.1	4	65000	148	159	0	0	0	02:16:01	0
10.0.23.2	4	65000	136	143	0	0	0	02:13:21	0
10.0.34.4	4	65004	161	163	0	0	0	02:16:01	1
10.0.35.5	4	65005	162	166	0	0	0	02:16:01	1

```
Total number of neighbors 4
```

Reset

reset <ip|ipv6> bgp <address> [soft [in|out]]

This command resets BGP connections to the specified neighbor IP address. With argument `soft` this command initiates a soft reset. If you do not specify the `in` or `out` options, both inbound and outbound soft reconfiguration are triggered.

reset ip bgp all

This command resets all BGP connections of given router.

reset ip bgp dampening

This command uses to clear BGP route dampening information and to unsuppress suppressed routes.

reset ip bgp external

This command resets all external BGP peers of given router.

reset ip bgp peer-group <name> [soft [in|out]]

This command resets BGP connections to the specified peer group. With argument `soft` this command initiates a soft reset. If you do not specify the `in` or `out` options, both inbound and outbound soft reconfiguration are triggered.

Examples

IPv4 peering

A simple eBGP configuration:

Node 1:

```
set protocols bgp local-as 65534
set protocols bgp neighbor 192.168.0.2 ebgp-multihop '2'
set protocols bgp neighbor 192.168.0.2 remote-as '65535'
set protocols bgp neighbor 192.168.0.2 update-source '192.168.0.1'
set protocols bgp address-family ipv4-unicast network '172.16.0.0/16'
set protocols bgp parameters router-id '192.168.0.1'
```

Node 2:

```
set protocols bgp local-as 65535
set protocols bgp neighbor 192.168.0.1 ebgp-multihop '2'
set protocols bgp neighbor 192.168.0.1 remote-as '65534'
set protocols bgp neighbor 192.168.0.1 update-source '192.168.0.2'
set protocols bgp address-family ipv4-unicast network '172.17.0.0/16'
set protocols bgp parameters router-id '192.168.0.2'
```

Don't forget, the CIDR declared in the network statement **MUST exist in your routing table (dynamic or static), the best way to make sure that is true is creating a static route:**

Node 1:

```
set protocols static route 172.16.0.0/16 blackhole distance '254'
```

Node 2:

```
set protocols static route 172.17.0.0/16 blackhole distance '254'
```

IPv6 peering

A simple BGP configuration via IPv6.

Node 1:

```
set protocols bgp local-as 65534
set protocols bgp neighbor 2001:db8::2 ebgp-multihop '2'
set protocols bgp neighbor 2001:db8::2 remote-as '65535'
set protocols bgp neighbor 2001:db8::2 update-source '2001:db8::1'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast
set protocols bgp address-family ipv6-unicast network '2001:db8:1::/48'
set protocols bgp parameters router-id '10.1.1.1'
```

Node 2:

```
set protocols bgp local-as 65535
set protocols bgp neighbor 2001:db8::1 ebgp-multihop '2'
set protocols bgp neighbor 2001:db8::1 remote-as '65534'
set protocols bgp neighbor 2001:db8::1 update-source '2001:db8::2'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast
```

(continues on next page)

(continued from previous page)

```
set protocols bgp address-family ipv6-unicast network '2001:db8:2::/48'
set protocols bgp parameters router-id '10.1.1.2'
```

Don't forget, the CIDR declared in the network statement **MUST exist in your routing table (dynamic or static), the best way to make sure that is true is creating a static route:**

Node 1:

```
set protocols static route6 2001:db8:1::/48 blackhole distance '254'
```

Node 2:

```
set protocols static route6 2001:db8:2::/48 blackhole distance '254'
```

Route Filtering

Route filter can be applied using a route-map:

Node1:

```
set policy prefix-list AS65535-IN rule 10 action 'permit'
set policy prefix-list AS65535-IN rule 10 prefix '172.16.0.0/16'
set policy prefix-list AS65535-OUT rule 10 action 'deny'
set policy prefix-list AS65535-OUT rule 10 prefix '172.16.0.0/16'
set policy prefix-list6 AS65535-IN rule 10 action 'permit'
set policy prefix-list6 AS65535-IN rule 10 prefix '2001:db8:2::/48'
set policy prefix-list6 AS65535-OUT rule 10 action 'deny'
set policy prefix-list6 AS65535-OUT rule 10 prefix '2001:db8:2::/48'

set policy route-map AS65535-IN rule 10 action 'permit'
set policy route-map AS65535-IN rule 10 match ip address prefix-list 'AS65535-IN'
set policy route-map AS65535-IN rule 10 match ipv6 address prefix-list 'AS65535-IN'
set policy route-map AS65535-IN rule 20 action 'deny'
set policy route-map AS65535-OUT rule 10 action 'deny'
set policy route-map AS65535-OUT rule 10 match ip address prefix-list 'AS65535-OUT'
set policy route-map AS65535-OUT rule 10 match ipv6 address prefix-list 'AS65535-OUT'
set policy route-map AS65535-OUT rule 20 action 'permit'

set protocols bgp local-as 65534
set protocols bgp neighbor 2001:db8::2 address-family ipv4-unicast route-map export
↪ 'AS65535-OUT'
set protocols bgp neighbor 2001:db8::2 address-family ipv4-unicast route-map import
↪ 'AS65535-IN'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast route-map export
↪ 'AS65535-OUT'
set protocols bgp neighbor 2001:db8::2 address-family ipv6-unicast route-map import
↪ 'AS65535-IN'
```

Node2:

```
set policy prefix-list AS65534-IN rule 10 action 'permit'
set policy prefix-list AS65534-IN rule 10 prefix '172.17.0.0/16'
set policy prefix-list AS65534-OUT rule 10 action 'deny'
set policy prefix-list AS65534-OUT rule 10 prefix '172.17.0.0/16'
set policy prefix-list6 AS65534-IN rule 10 action 'permit'
```

(continues on next page)

(continued from previous page)

```

set policy prefix-list6 AS65534-IN rule 10 prefix '2001:db8:1::/48'
set policy prefix-list6 AS65534-OUT rule 10 action 'deny'
set policy prefix-list6 AS65534-OUT rule 10 prefix '2001:db8:1::/48'

set policy route-map AS65534-IN rule 10 action 'permit'
set policy route-map AS65534-IN rule 10 match ip address prefix-list 'AS65534-IN'
set policy route-map AS65534-IN rule 10 match ipv6 address prefix-list 'AS65534-IN'
set policy route-map AS65534-IN rule 20 action 'deny'
set policy route-map AS65534-OUT rule 10 action 'deny'
set policy route-map AS65534-OUT rule 10 match ip address prefix-list 'AS65534-OUT'
set policy route-map AS65534-OUT rule 10 match ipv6 address prefix-list 'AS65534-OUT'
set policy route-map AS65534-OUT rule 20 action 'permit'

set protocols bgp local-as 65535
set protocols bgp neighbor 2001:db8::1 address-family ipv4-unicast route-map export
↪ 'AS65534-OUT'
set protocols bgp neighbor 2001:db8::1 address-family ipv4-unicast route-map import
↪ 'AS65534-IN'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast route-map export
↪ 'AS65534-OUT'
set protocols bgp neighbor 2001:db8::1 address-family ipv6-unicast route-map import
↪ 'AS65534-IN'

```

We could expand on this and also deny link local and multicast in the rule 20 action deny.

8.9.3 Multicast

VyOS facilitates IP Multicast by supporting **PIM Sparse Mode**, **IGMP** and **IGMP-Proxy**.

PIM and IGMP

PIM (Protocol Independent Multicast) must be configured in every interface of every participating router. Every router must also have the location of the Rendezvous Point manually configured. Then, unidirectional shared trees rooted at the Rendezvous Point will automatically be built for multicast distribution.

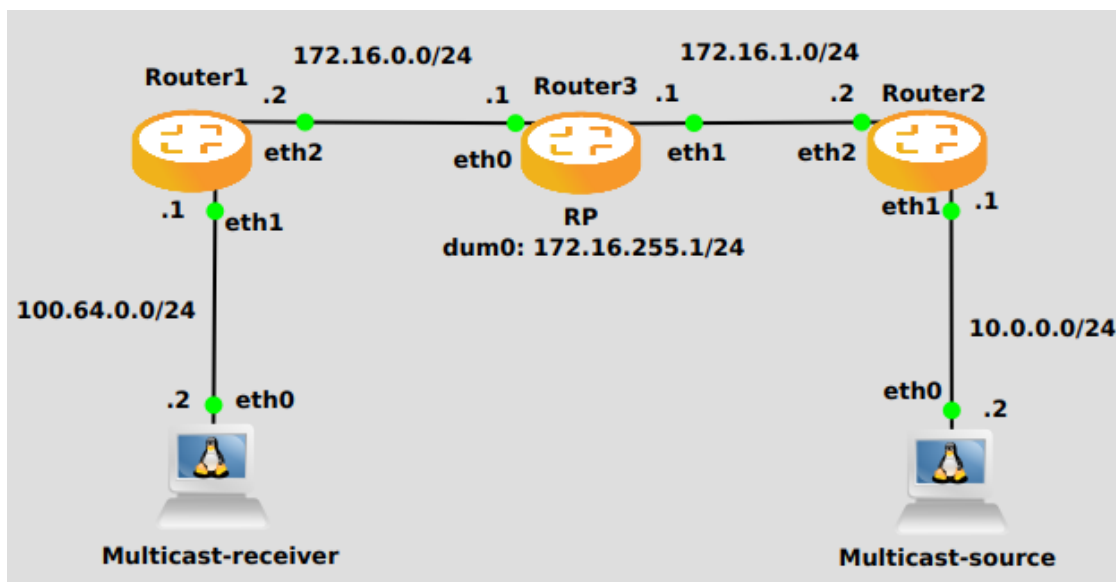

Traffic from multicast sources will go to the Rendezvous Point, and receivers will pull it from a shared tree using IGMP (Internet Group Management Protocol).

Multicast receivers will talk IGMP to their local router, so, besides having PIM configured in every router, IGMP must also be configured in any router where there could be a multicast receiver locally connected.

VyOS supports both IGMP version 2 and version 3 (which allows source-specific multicast).

Example

In the following example we can see a basic multicast setup:

Router 1

```
set interfaces ethernet eth2 address '172.16.0.2/24'
set interfaces ethernet eth1 address '100.64.0.1/24'
set protocols ospf area 0 network '172.16.0.0/24'
set protocols ospf area 0 network '100.64.0.0/24'
set protocols igmp interface eth1
set protocols pim interface eth1
set protocols pim interface eth2
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

Router 3

```
set interfaces dummy dum0 address '172.16.255.1/24'
set interfaces ethernet eth0 address '172.16.0.1/24'
set interfaces ethernet eth1 address '172.16.1.1/24'
set protocols ospf area 0 network '172.16.0.0/24'
set protocols ospf area 0 network '172.16.255.0/24'
set protocols ospf area 0 network '172.16.1.0/24'
set protocols pim interface dum0
set protocols pim interface eth0
set protocols pim interface eth1
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

Router 2

```
set interfaces ethernet eth1 address '10.0.0.1/24'
set interfaces ethernet eth2 address '172.16.1.2/24'
set protocols ospf area 0 network '10.0.0.0/24'
set protocols ospf area 0 network '172.16.1.0/24'
set protocols pim interface eth1
set protocols pim interface eth2
set protocols pim rp address 172.16.255.1 group '224.0.0.0/4'
```

Basic commands

These are the commands for a basic setup.

```
set protocols pim interface <interface-name>
```

Use this command to enable PIM in the selected interface so that it can communicate with PIM neighbors.

```
set protocols pim rp address <address> group <multicast-address/mask-bits>
```

Use this command to manually configure a Rendezvous Point for PIM so that join messages can be sent there. Set the Rendezvous Point address and the matching prefix of group ranges covered. These values must be shared with every router participating in the PIM network.

```
set protocols igmp interface eth1
```

Use this command to configure an interface with IGMP so that PIM can receive IGMP reports and query on the selected interface. By default IGMP version 3 will be used.

Tuning commands

You can also tune multicast with the following commands.

```
set protocols pim interface <interface> dr-priority <value>
```

Use this PIM command in the selected interface to set the priority (1-4294967295) you want to influence in the election of a node to become the Designated Router for a LAN segment. The default priority is 1, set a higher value to give the router more preference in the DR election process.

```
set protocols pim int <interface> hello <seconds>
```

Use this command to configure the PIM hello interval in seconds (1-180) for the selected interface.

```
set protocols pim rp keep-alive-timer <seconds>
```

Use this PIM command to modify the the time out value (31-60000 seconds) for an (S,G) flow. 31 seconds is chosen for a lower bound as some hardware platforms cannot see data flowing in better than 30 second chunks.

```
set protocols igmp interface <interface> join <multicast-address> source  
<IP-address>
```

Use this command to allow the selected interface join a multicast group defining the multicast address you want to join and the source IP address too.

```
set protocols igmp interface <interface> query-interval <seconds>
```

Use this command to configure in the selected interface the IGMP host query interval (1-1800) in seconds that PIM will use.

```
set protocols igmp interface <interface> query-max-response-time <deciseconds>
```

Use this command to configure in the selected interface the IGMP query response timeout value (10-250) in deciseconds. If a report is not returned in the specified time, it will be assumed the (S,G) or (*,G) state has timed out.

```
set protocols igmp interface <interface> version <version-number>
```

Use this command to define in the selected interface whether you choose IGMP version 2 or 3. The default value is 3.

IGMP Proxy

IGMP (Internet Group Management Protocol) proxy sends IGMP host messages on behalf of a connected client. The configuration must define one, and only one upstream interface, and one or more downstream interfaces.

Configuration

set protocols igmp-proxy interface <interface> role <upstream | downstream>

- **upstream:** The upstream network interface is the outgoing interface which is responsible for communicating to available multicast data sources. There can only be one upstream interface.
- **downstream:** Downstream network interfaces are the distribution interfaces to the destination networks, where multicast clients can join groups and receive multicast data. One or more downstream interfaces must be configured.

set protocols igmp-proxy interface <interface> alt-subnet <network>

Defines alternate sources for multicasting and IGMP data. The network address must be on the following format 'a.b.c.d/n'. By default the router will accept data from sources on the same network as configured on an interface. If the multicast source lies on a remote network, one must define from where traffic should be accepted.

This is especially useful for the upstream interface, since the source for multicast traffic is often from a remote location.

This option can be supplied multiple times.

set protocols igmp-proxy disable-quickleave

Disables quickleave mode. In this mode the daemon will not send a Leave IGMP message upstream as soon as it receives a Leave message for any downstream interface. The daemon will not ask for Membership reports on the downstream interfaces, and if a report is received the group is not joined again upstream.

If it's vital that the daemon should act exactly as a real multicast client on the upstream interface, this function should be enabled.

Enabling this function increases the risk of bandwidth saturation.

set protocols igmp-proxy disable

Disable this service.

Example

Interface *eth1* LAN is behind NAT. In order to subscribe *10.0.0.0/23* subnet multicast which is in *eth0* WAN we need to configure igmp-proxy.

```
set protocols igmp-proxy interface eth0 role upstream
set protocols igmp-proxy interface eth0 alt-subnet 10.0.0.0/23
set protocols igmp-proxy interface eth1 role downstream
```

Operation

restart igmp-proxy

Restart the IGMP proxy process.

8.9.4 IS-IS

IS-IS (Intermediate System to Intermediate System) is a link-state interior gateway routing protocol which is described in ISO10589, [RFC 1195](#), [RFC 5308](#). Like OSPF, IS-IS runs the Dijkstra shortest-path first (SPF) algorithm to create a

database of the network's topology and, from that database, to determine the best (that is, shortest) path to a destination. The routers exchange topology information with their nearest neighbors. IS-IS runs directly on the data link layer (Layer 2). IS-IS addresses are called NETs (Network Entity Titles) and can be 8 to 20 bytes long, but are generally 10 bytes long.

General

Configuration

Mandatory Settings

set protocols isis net <network-entity-title>

This command also sets network entity title (NET) provided in ISO format.

For example NET (Network Entity Title)

```
49.0001.1921.6800.1002.00
```

The IS-IS address consists of the following parts:

- AFI (Address family authority identifier) - 49 The AFI value 49 is what IS-IS uses for private addressing.
- Area identifier: 0001 IS-IS area number (Area1)
- System identifier: 1921.6800.1002 - for system identifiers we recommend to use IP address or MAC address of the router itself.
- NET selector: 00 Must always be 00, to indicate "this system".

set protocols isis interface <interface>

This command activates ISIS adjacency on this interface. Note that the name of ISIS instance must be the same as the one used to configure the ISIS process.

set protocols isis dynamic-hostname

This command enables support for dynamic hostname. Dynamic hostname mapping determined as described in [RFC 2763](#), Dynamic Hostname Exchange Mechanism for IS-IS.

set protocols isis level <level-1|level-1-2|level-2>

This command defines the ISIS router behavior:

level-1 Act as a station router only. **level-1-2** Act as both a station router and an area router. **level-2-only** Act as an area router only.

set protocols isis lsp-mtu <size>

This command configures the maximum size of generated LSPs, in bytes. The size range is 128 to 4352.

set protocols isis metric-style <narrow|transition|wide>

This command sets old-style (ISO 10589) or new-style packet formats:

narrow Use old style of TLVs with narrow metric. **transition** Send and accept both styles of TLVs during transition. **wide** Use new style of TLVs to carry wider metric.

set protocols isis purge-originator

This command enables [RFC 6232](#) purge originator identification. Enable purge originator identification (POI) by adding the type, length and value (TLV) with the Intermediate System (IS) identification to the LSPs that do

not contain POI information. If an IS generates a purge, VyOS adds this TLV with the system ID of the IS to the purge.

```
set protocols isis set-attached-bit
```

This command sets ATT bit to 1 in Level1 LSPs. It is described in [RFC 3787](#).

```
set protocols isis set-overload-bit
```

This command sets overload bit to avoid any transit traffic through this router. It is described in [RFC 3787](#).

```
set protocols isis name default-information originate <ipv4|ipv6> level-1
```

This command will generate a default-route in L1 database.

```
set protocols isis name default-information originate <ipv4|ipv6> level-2
```

This command will generate a default-route in L2 database.

Interface Configuration

```
set protocols isis interface <interface> circuit-type <level-1|level-1-2|level-2-only>
```

This command specifies circuit type for interface:

- **level-1** Level-1 only adjacencies are formed.
- **level-1-2** Level-1-2 adjacencies are formed
- **level-2-only** Level-2 only adjacencies are formed

```
set protocols isis interface <interface> hello-interval <seconds>
```

This command sets hello interval in seconds on a given interface. The range is 1 to 600.

```
set protocols isis interface <interface> hello-multiplier <seconds>
```

This command sets multiplier for hello holding time on a given interface. The range is 2 to 100.

```
set protocols isis interface <interface> hello-padding
```

This command configures padding on hello packets to accommodate asymmetrical maximum transfer units (MTUs) from different hosts as described in [RFC 3719](#). This helps to prevent a premature adjacency Up state when one routing devices MTU does not meet the requirements to establish the adjacency.

```
set protocols isis interface <interface> metric <metric>
```

This command set default metric for circuit.

The metric range is 1 to 16777215 (Max value depend if metric support narrow or wide value).

```
set protocols isis interface <interface> network point-to-point
```

This command specifies network type to Point-to-Point. The default network type is broadcast.

```
set protocols isis interface <interface> passive
```

This command configures the passive mode for this interface.

```
set protocols isis interface <interface> password plaintext-password <text>
```

This command configures the authentication password for the interface.

```
set protocols isis interface <interface> priority <number>
```

This command sets priority for the interface for DIS (Designated Intermediate System) election. The priority range is 0 to 127.

```
set protocols isis interface <interface> psnp-interval <number>
```

This command sets PSNP interval in seconds. The interval range is 0 to 127.

```
set protocols isis interface <interface> no-three-way-handshake
```

This command disables Three-Way Handshake for P2P adjacencies which described in [RFC 5303](#). Three-Way Handshake is enabled by default.

Route Redistribution

```
set protocols isis redistribute ipv4 <route source> level-1
```

This command redistributes routing information from the given route source into the ISIS database as Level-1. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

```
set protocols isis redistribute ipv4 <route source> level-2
```

This command redistributes routing information from the given route source into the ISIS database as Level-2. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

```
set protocols isis redistribute ipv4 <route source> <level-1|level-2> metric <number>
```

This command specifies metric for redistributed routes from the given route source. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static. The metric range is 1 to 16777215.

```
set protocols isis redistribute ipv4 <route source> <level-1|level-2>  
route-map <name>
```

This command allows to use route map to filter redistributed routes from the given route source. There are six modes available for route source: bgp, connected, kernel, ospf, rip, static.

Timers

```
set protocols isis lsp-gen-interval <seconds>
```

This command sets minimum interval in seconds between regenerating same LSP. The interval range is 1 to 120.

```
set protocols isis lsp-refresh-interval <seconds>
```

This command sets LSP refresh interval in seconds. IS-IS generates LSPs when the state of a link changes. However, to ensure that routing databases on all routers remain converged, LSPs in stable networks are generated on a regular basis even though there has been no change to the state of the links. The interval range is 1 to 65235. The default value is 900 seconds.

```
set protocols isis max-lsp-lifetime <seconds>
```

This command sets LSP maximum LSP lifetime in seconds. The interval range is 350 to 65535. LSPs remain in a database for 1200 seconds by default. If they are not refreshed by that time, they are deleted. You can change the LSP refresh interval or the LSP lifetime. The LSP refresh interval should be less than the LSP lifetime or else LSPs will time out before they are refreshed.

```
set protocols isis spf-interval <seconds>
```

This command sets minimum interval between consecutive SPF calculations in seconds. The interval range is 1 to 120.

```
set protocols isis spf-delay-ietf holddown <milliseconds>
```

```

set protocols isis spf-delay-ietf init-delay <milliseconds>
set protocols isis spf-delay-ietf long-delay <milliseconds>
set protocols isis spf-delay-ietf short-delay <milliseconds>
set protocols isis spf-delay-ietf time-to-learn <milliseconds>

```

This commands specifies the Finite State Machine (FSM) intended to control the timing of the execution of SPF calculations in response to IGP events. The process described in [RFC 8405](#).

Example

Simple IS-IS configuration using 2 nodes and redistributing connected interfaces.

Node 1:

```

set interfaces dummy dum0 address '203.0.113.1/24'
set interfaces ethernet eth1 address '192.0.2.1/24'

set policy prefix-list EXPORT-ISIS rule 10 action 'permit'
set policy prefix-list EXPORT-ISIS rule 10 prefix '203.0.113.0/24'
set policy route-map EXPORT-ISIS rule 10 action 'permit'
set policy route-map EXPORT-ISIS rule 10 match ip address prefix-list 'EXPORT-ISIS'

set protocols isis interface eth1
set protocols isis net '49.0001.1921.6800.1002.00'
set protocols isis redistribute ipv4 connected level-2 route-map 'EXPORT-ISIS'

```

Node 2:

```

set interfaces ethernet eth1 address '192.0.2.2/24'

set protocols isis interface eth1
set protocols isis net '49.0001.1921.6800.2002.00'

```

Show ip routes on Node2:

```

vyos@r2:~$ show ip route isis
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

I   203.0.113.0/24 [115/10] via 192.0.2.1, eth1, 00:03:42

```

8.9.5 MPLS

MPLS (Multi-Protocol Label Switching) is a packet forwarding paradigm which differs from regular IP forwarding. Instead of IP addresses being used to make the decision on finding the exit interface, a router will instead use an exact match on a 32 bit/4 byte header called the MPLS label. This label is inserted between the ethernet (layer 2) header and the IP (layer 3) header. One can statically or dynamically assign label allocations, but we will focus on dynamic allocation of labels using some sort of label distribution protocol (such as the aptly named Label Distribution Protocol / LDP, Resource Reservation Protocol / RSVP, or Segment Routing through OSPF/ISIS). These protocols allow for the creation of a unidirectional/unicast path called a labeled switched path (initialized as LSP) throughout the network that operates very much like a tunnel through the network. An easy way of thinking about how an MPLS LSP actually

forwards traffic throughout a network is to think of a GRE tunnel. They are not the same in how they operate, but they are the same in how they handle the tunneled packet. It would be good to think of MPLS as a tunneling technology that can be used to transport many different types of packets, to aid in traffic engineering by allowing one to specify paths throughout the network (using RSVP or SR), and to generally allow for easier intra/inter network transport of data packets.

For more information on how MPLS label switching works, please go visit [Wikipedia \(MPLS\)](#).

Note: MPLS support in VyOS is not finished yet, and therefore its functionality is limited. Currently there is no support for MPLS enabled VPN services such as L3VPNs, L2VPNs, and mVPNs. RSVP support is also not present as the underlying routing stack (FRR) does not implement it. Currently VyOS can be configured as a label switched router (MPLS P router), in both penultimate and ultimate hop popping operations.

Label Distribution Protocol

The MPLS architecture does not assume a single protocol to create MPLS paths. VyOS supports the Label Distribution Protocol (LDP) as implemented by FRR, based on [RFC 5036](#).

LDP (Label Distribution Protocol) is a TCP based MPLS signaling protocol that distributes labels creating MPLS label switched paths in a dynamic manner. LDP is not a routing protocol, as it relies on other routing protocols for forwarding decisions. LDP cannot bootstrap itself, and therefore relies on said routing protocols for communication with other routers that use LDP.

In order to allow for LDP on the local router to exchange label advertisements with other routers, a TCP session will be established between automatically discovered and statically assigned routers. LDP will try to establish a TCP session to the **transport address** of other routers. Therefore for LDP to function properly please make sure the transport address is shown in the routing table and reachable to traffic at all times.

It is highly recommended to use the same address for both the LDP router-id and the discovery transport address, but for VyOS MPLS LDP to work both parameters must be explicitly set in the configuration.

Another thing to keep in mind with LDP is that much like BGP, it is a protocol that runs on top of TCP. It however does not have an ability to do something like a refresh capability like BGP's route refresh capability. Therefore one might have to reset the neighbor for a capability change or a configuration change to work.

Configuration Options

```
set protocols mpls ldp interface <interface>
```

Use this command to enable LDP, and enable MPLS processing on the interface you define.

```
set protocols mpls ldp router-id <address>
```

Use this command to configure the IP address used as the LDP router-id of the local device.

```
set protocols mpls ldp discovery transport-ipv4-address <address>
```

```
set protocols mpls ldp discovery transport-ipv6-address <address>
```

Use this command to set the IPv4 or IPv6 transport-address used by LDP.

```
set protocols mpls ldp neighbor <address> password <password>
```

Use this command to configure authentication for LDP peers. Set the IP address of the LDP peer and a password that should be shared in order to become neighbors.

```
set protocols mpls ldp neighbor <address> session-holdtime <seconds>
```

Use this command to configure a specific session hold time for LDP peers. Set the IP address of the LDP peer and a session hold time that should be configured for it. You may have to reset the neighbor for this to work.

```
set protocols mpls ldp neighbor <address> ttl-security <disable | hop count>
```

Use this command to enable, disable, or specify hop count for TTL security for LDP peers. By default the value is set to 255 (or max TTL).

```
set protocols mpls ldp discovery hello-ipv4-interval <seconds>
```

```
set protocols mpls ldp discovery hello-ipv4-holdtime <seconds>
```

```
set protocols mpls ldp discovery hello-ipv6-interval <seconds>
```

```
set protocols mpls ldp discovery hello-ipv6-holdtime <seconds>
```

Use these commands if you would like to set the discovery hello and hold time parameters.

```
set protocols mpls ldp discovery session-ipv4-holdtime <seconds>
```

```
set protocols mpls ldp discovery session-ipv6-holdtime <seconds>
```

Use this command if you would like to set the TCP session hold time intervals.

```
set protocols mpls ldp import ipv4 import-filter filter-access-list <access list number>
```

```
set protocols mpls ldp import ipv6 import-filter filter-access-list6 <access list number>
```

Use these commands to control the importing of forwarding equivalence classes (FECs) for LDP from neighbors. This would be useful for example on only accepting the labeled routes that are needed and not ones that are not needed, such as accepting loopback interfaces and rejecting all others.

```
set protocols mpls ldp export ipv4 export-filter filter-access-list <access list number>
```

```
set protocols mpls ldp export ipv6 export-filter filter-access-list6 <access list number>
```

Use these commands to control the exporting of forwarding equivalence classes (FECs) for LDP to neighbors. This would be useful for example on only announcing the labeled routes that are needed and not ones that are not needed, such as announcing loopback interfaces and no others.

```
set protocols mpls ldp export ipv4 explicit-null
```

```
set protocols mpls ldp export ipv6 explicit-null
```

Use this command if you would like for the router to advertise FECs with a label of 0 for explicit null operations.

```
set protocols mpls ldp allocation ipv4 access-list <access list number>
```

```
set protocols mpls ldp allocation ipv6 access-list6 <access list number>
```

Use this command if you would like to control the local FEC allocations for LDP. A good example would be for your local router to not allocate a label for everything. Just a label for what it's useful. A good example would be just a loopback label.

```
set protocols mpls ldp parameters cisco-interop-tlv
```

Use this command to use a Cisco non-compliant format to send and interpret the Dual-Stack capability TLV for IPv6 LDP communications. This is related to [RFC 7552](#).

```
set protocols mpls ldp parameters ordered-control
```

Use this command to use ordered label distribution control mode. FRR by default uses independent label distribution control mode for label distribution. This is related to [RFC 5036](#).

set protocols mpls ldp parameters transport-prefer-ipv4

Use this command to prefer IPv4 for TCP peer transport connection for LDP when both an IPv4 and IPv6 LDP address are configured on the same interface.

set protocols mpls ldp targeted-neighbor ipv4 enable**set protocols mpls ldp targeted-neighbor ipv6 enable**

Use this command to enable targeted LDP sessions to the local router. The router will then respond to any sessions that are trying to connect to it that are not a link local type of TCP connection.

set protocols mpls ldp targeted-neighbor ipv4 address <address>**set protocols mpls ldp targeted-neighbor ipv6 address <address>**

Use this command to enable the local router to try and connect with a targeted LDP session to another router.

set protocols mpls ldp targeted-neighbor ipv4 hello-holdtime <seconds>**set protocols mpls ldp targeted-neighbor ipv4 hello-interval <seconds>****set protocols mpls ldp targeted-neighbor ipv6 hello-holdtime <seconds>****set protocols mpls ldp targeted-neighbor ipv6 hello-interval <seconds>**

Use these commands if you would like to set the discovery hello and hold time parameters for the targeted LDP neighbors.

Sample configuration to setup LDP on VyOS

```

set protocols ospf area 0 network '192.168.255.252/32'           <---_
↪Routing for loopback
set protocols ospf area 0 network '192.168.0.5/32'             <---_
↪Routing for an interface connecting to the network
set protocols ospf parameters router-id '192.168.255.252'       <---_
↪Router ID setting for OSPF
set protocols mpls ldp discovery transport-ipv4-address '192.168.255.252' <---_
↪Transport address for LDP for TCP sessions to connect to
set protocols mpls ldp interface 'eth1'                        <---_
↪Enable MPLS and LDP for an interface connecting to network
set protocols mpls ldp interface 'lo'                          <---_
↪Enable MPLS and LDP on loopback for future services connectivity
set protocols mpls ldp router-id '192.168.255.252'             <---_
↪Router ID setting for LDP
set interfaces ethernet eth1 address '192.168.0.5/31'          <---_
↪Interface IP for connecting to network
set interfaces loopback lo address '192.168.255.252/32'        <---_
↪Interface loopback IP for router ID and other uses

```

Operational Mode Commands

When LDP is working, you will be able to see label information in the outcome of `show ip route`. Besides that information, there are also specific *show* commands for LDP:

Show**show mpls ldp binding**

Use this command to see the Label Information Base.

```
show mpls ldp discovery
```

Use this command to see discovery hello information

```
show mpls ldp interface
```

Use this command to see LDP interface information

```
show mpls ldp neighbor
```

Use this command to see LDP neighbor information

```
show mpls ldp neighbor detail
```

Use this command to see detailed LDP neighbor information

Reset

```
reset mpls ldp neighbor <IPv4 or IPv6 address>
```

Use this command to reset an LDP neighbor/TCP session that is established

8.9.6 OSPF

OSPF (Open Shortest Path First) is a routing protocol for Internet Protocol (IP) networks. It uses a link state routing (LSR) algorithm and falls into the group of interior gateway protocols (IGPs), operating within a single autonomous system (AS). It is defined as OSPF Version 2 in [RFC 2328](#) (1998) for IPv4. Updates for IPv6 are specified as OSPF Version 3 in [RFC 5340](#) (2008). OSPF supports the CIDR (Classless Inter-Domain Routing) addressing model.

OSPF is a widely used IGP in large enterprise networks.

OSPFv2 (IPv4)

Configuration

General

VyOS does not have a special command to start the OSPF process. The OSPF process starts when the first ospf enabled interface is configured.

```
set protocols ospf area <number> network <A.B.C.D/M>
```

This command specifies the OSPF enabled interface(s). If the interface has an address from defined range then the command enables OSPF on this interface so router can provide network information to the other ospf routers via this interface.

This command is also used to enable the OSPF process. The area number can be specified in decimal notation in the range from 0 to 4294967295. Or it can be specified in dotted decimal notation similar to ip address.

```
set protocols ospf auto-cost reference-bandwidth <number>
```

This command sets the reference bandwidth for cost calculations, where bandwidth can be in range from 1 to 4294967, specified in Mbits/s. The default is 100Mbit/s (i.e. a link of bandwidth 100Mbit/s or higher will have a cost of 1. Cost of lower bandwidth links will be scaled with reference to this cost).

```
set protocols ospf parameters router-id <rid>
```

This command sets the router-ID of the OSPF process. The router-ID may be an IP address of the router, but need not be – it can be any arbitrary 32bit number. However it **MUST** be unique within the entire OSPF domain to the OSPF speaker – bad things will happen if multiple OSPF speakers are configured with the same router-ID!

Optional

```
set protocols ospf default-information originate [always] [metric <number>]
[metric-type <1|2>] [route-map <name>]
```

Originate an AS-External (type-5) LSA describing a default route into all external-routing capable areas, of the specified metric and metric type. If the `always` keyword is given then the default is always advertised, even when there is no default present in the routing table. The argument `route-map` specifies to advertise the default route if the route map is satisfied.

```
set protocols ospf distance global <distance>
```

This command change distance value of OSPF globally. The distance range is 1 to 255.

```
set protocols ospf distance ospf <external|inter-area|intra-area> <distance>
```

This command change distance value of OSPF. The arguments are the distance values for external routes, inter-area routes and intra-area routes respectively. The distance range is 1 to 255.

Note: Routes with a distance of 255 are effectively disabled and not installed into the kernel.

```
set protocols ospf log-adjacency-changes [detail]
```

This command allows to log changes in adjacency. With the optional `detail` argument, all changes in adjacency status are shown. Without `detail`, only changes to full or regressions are shown.

```
set protocols ospf max-metric router-lsa <administrative|on-shutdown>
<seconds>|on-startup <seconds>>
```

This enables [RFC 3137](#) support, where the OSPF process describes its transit links in its router-LSA as having infinite distance so that other routers will avoid calculating transit paths through the router while still being able to reach networks through the router.

This support may be enabled administratively (and indefinitely) with the `administrative` command. It may also be enabled conditionally. Conditional enabling of max-metric router-lsas can be for a period of seconds after startup with the `on-startup <seconds>` command and/or for a period of seconds prior to shutdown with the `on-shutdown <seconds>` command. The time range is 5 to 86400.

```
set protocols ospf parameters abr-type <cisco|ibm|shortcut|standard>
```

This command selects ABR model. OSPF router supports four ABR models:

cisco – a router will be considered as ABR if it has several configured links to the networks in different areas one of which is a backbone area. Moreover, the link to the backbone area should be active (working). **ibm** – identical to “cisco” model but in this case a backbone area link may not be active. **standard** – router has several active links to different areas. **shortcut** – identical to “standard” but in this model a router is allowed to use a connected areas topology without involving a backbone area for inter-area connections.

Detailed information about “cisco” and “ibm” models differences can be found in [RFC 3509](#). A “shortcut” model allows ABR to create routes between areas based on the topology of the areas connected to this router but not using a backbone area in case if non-backbone route will be cheaper. For more information about “shortcut” model, see *ospf-shortcut-abr-02.txt*

```
set protocols ospf parameters rfc1583-compatibility
```

RFC 2328, the successor to **RFC 1583**, suggests according to section G.2 (changes) in section 16.4.1 a change to the path preference algorithm that prevents possible routing loops that were possible in the old version of OSPFv2. More specifically it demands that inter-area paths and intra-area backbone path are now of equal preference but still both preferred to external paths.

This command should NOT be set normally.

set protocols ospf passive-interface <interface>

This command specifies interface as passive. Passive interface advertises its address, but does not run the OSPF protocol (adjacencies are not formed and hello packets are not generated).

set protocols ospf passive-interface default

This command specifies all interfaces as passive by default. Because this command changes the configuration logic to a default passive; therefore, interfaces where router adjacencies are expected need to be configured with the `passive-interface-exclude` command.

set protocols ospf passive-interface-exclude <interface>

This command allows exclude interface from passive state. This command is used if the command `passive-interface default` was configured.

set protocols ospf refresh timers <seconds>

The router automatically updates link-state information with its neighbors. Only an obsolete information is updated which age has exceeded a specific threshold. This parameter changes a threshold value, which by default is 1800 seconds (half an hour). The value is applied to the whole OSPF router. The timer range is 10 to 1800.

**set protocols ospf timers throttle spf <delay|initial-holdtime|max-holdtime>
<seconds>**

This command sets the initial delay, the initial-holdtime and the maximum-holdtime between when SPF is calculated and the event which triggered the calculation. The times are specified in milliseconds and must be in the range of 0 to 600000 milliseconds. `delay` sets the initial SPF schedule delay in milliseconds. The default value is 200 ms. `initial-holdtime` sets the minimum hold time between two consecutive SPF calculations. The default value is 1000 ms. `max-holdtime` sets the maximum wait time between two consecutive SPF calculations. The default value is 10000 ms.

Area Configuration

set protocols ospf area <number> area-type stub

This command specifies the area to be a Stub Area. That is, an area where no router originates routes external to OSPF and hence an area where all external routes are via the ABR(s). Hence, ABRs for such an area do not need to pass AS-External LSAs (type-5) or ASBR-Summary LSAs (type-4) into the area. They need only pass Network-Summary (type-3) LSAs into such an area, along with a default-route summary.

set protocols ospf area <number> area-type stub no-summary

This command specifies the area to be a Totally Stub Area. In addition to stub area limitations this area type prevents an ABR from injecting Network-Summary (type-3) LSAs into the specified stub area. Only default summary route is allowed.

set protocols ospf area <number> area-type stub default-cost <number>

This command sets the cost of default-summary LSAs announced to stubby areas. The cost range is 0 to 16777215.

set protocols ospf area <number> area-type nssa

This command specifies the area to be a Not So Stubby Area. External routing information is imported into an NSSA in Type-7 LSAs. Type-7 LSAs are similar to Type-5 AS-external LSAs, except that they can only be flooded into the NSSA. In order to further propagate the NSSA external information, the Type-7 LSA must be translated to a Type-5 AS-external-LSA by the NSSA ABR.

```
set protocols ospf area <number> area-type nssa no-summary
```

This command specifies the area to be a NSSA Totally Stub Area. ABRs for such an area do not need to pass Network-Summary (type-3) LSAs (except the default summary route), ASBR-Summary LSAs (type-4) and AS-External LSAs (type-5) into the area. But Type-7 LSAs that convert to Type-5 at the NSSA ABR are allowed.

```
set protocols ospf area <number> area-type nssa default-cost <number>
```

This command sets the default cost of LSAs announced to NSSA areas. The cost range is 0 to 16777215.

```
set protocols ospf area <number> area-type nssa translate  
<always|candidate|never>
```

Specifies whether this NSSA border router will unconditionally translate Type-7 LSAs into Type-5 LSAs. When role is Always, Type-7 LSAs are translated into Type-5 LSAs regardless of the translator state of other NSSA border routers. When role is Candidate, this router participates in the translator election to determine if it will perform the translations duties. When role is Never, this router will never translate Type-7 LSAs into Type-5 LSAs.

```
set protocols ospf area <number> authentication plaintext-password
```

This command specifies that simple password authentication should be used for the given area. The password must also be configured on a per-interface basis.

```
set protocols ospf area <number> authentication md5
```

This command specify that OSPF packets must be authenticated with MD5 HMACs within the given area. Keying material must also be configured on a per-interface basis.

```
set protocols ospf area <number> range <A.B.C.D/M> [cost <number>]
```

This command summarizes intra area paths from specified area into one summary-LSA (Type-3) announced to other areas. This command can be used only in ABR and ONLY router-LSAs (Type-1) and network-LSAs (Type-2) (i.e. LSAs with scope area) can be summarized. AS-external-LSAs (Type-5) can't be summarized - their scope is AS. The optional argument `cost` specifies the aggregated link metric. The metric range is 0 to 16777215.

```
set protocols ospf area <number> range <A.B.C.D/M> not-advertise
```

This command instead of summarizing intra area paths filter them - i.e. intra area paths from this range are not advertised into other areas. This command makes sense in ABR only.

```
set protocols ospf area <number> range <A.B.C.D/M> substitute <E.F.G.H/M>
```

One Type-3 summary-LSA with routing info <E.F.G.H/M> is announced into backbone area if defined area contains at least one intra-area network (i.e. described with router-LSA or network-LSA) from range <A.B.C.D/M>. This command makes sense in ABR only.

```
set protocols ospf area <number> shortcut <default|disable|enable>
```

This parameter allows to “shortcut” routes (non-backbone) for inter-area routes. There are three modes available for routes shortcutting:

default – this area will be used for shortcutting only if ABR does not have a link to the backbone area or this link was lost. **enable** – the area will be used for shortcutting every time the route that goes through it is cheaper. **disable** – this area is never used by ABR for routes shortcutting.

```
set protocols ospf area <number> virtual-link <A.B.C.D>
```

Provides a backbone area coherence by virtual link establishment.

In general, OSPF protocol requires a backbone area (area 0) to be coherent and fully connected. I.e. any backbone area router must have a route to any other backbone area router. Moreover, every ABR must have a link to backbone area. However, it is not always possible to have a physical link to a backbone area. In this case between two ABR (one of them has a link to the backbone area) in the area (not stub area) a virtual link is organized.

<number> – area identifier through which a virtual link goes. <A.B.C.D> – ABR router-id with which a virtual link is established. Virtual link must be configured on both routers.

Formally, a virtual link looks like a point-to-point network connecting two ABR from one area one of which physically connected to a backbone area. This pseudo-network is considered to belong to a backbone area.

Interface Configuration

```
set protocols ospf interface <interface> authentication plaintext-password <text>
```

This command sets OSPF authentication key to a simple password. After setting, all OSPF packets are authenticated. Key has length up to 8 chars.

Simple text password authentication is insecure and deprecated in favour of MD5 HMAC authentication.

```
set protocols ospf interface <interface> authentication md5 key-id <id>  
md5-key <text>
```

This command specifies that MD5 HMAC authentication must be used on this interface. It sets OSPF authentication key to a cryptographic password. Key-id identifies secret key used to create the message digest. This ID is part of the protocol and must be consistent across routers on a link. The key can be long up to 16 chars (larger strings will be truncated), and is associated with the given key-id.

```
set protocols ospf interface <interface> bandwidth <number>
```

This command sets the interface bandwidth for cost calculations, where bandwidth can be in range from 1 to 100000, specified in Mbits/s.

```
set protocols ospf interface <interface> cost <number>
```

This command sets link cost for the specified interface. The cost value is set to router-LSA's metric field and used for SPF calculation. The cost range is 1 to 65535.

```
set protocols ospf interface <interface> dead-interval <number>
```

Set number of seconds for router Dead Interval timer value used for Wait Timer and Inactivity Timer. This value must be the same for all routers attached to a common network. The default value is 40 seconds. The interval range is 1 to 65535.

```
set protocols ospf interface <interface> hello-multiplier <number>
```

The hello-multiplier specifies how many Hellos to send per second, from 1 (every second) to 10 (every 100ms). Thus one can have 1s convergence time for OSPF. If this form is specified, then the hello-interval advertised in Hello packets is set to 0 and the hello-interval on received Hello packets is not checked, thus the hello-multiplier need NOT be the same across multiple routers on a common link.

```
set protocols ospf interface <interface> hello-interval <number>
```

Set number of seconds for Hello Interval timer value. Setting this value, Hello packet will be sent every timer value seconds on the specified interface. This value must be the same for all routers attached to a common network. The default value is 10 seconds. The interval range is 1 to 65535.

```
set protocols ospf interface <interface> bfd
```

This command enables BFD on this OSPF link interface.

```
set protocols ospf interface <interface> mtu-ignore
```

This command disables check of the MTU value in the OSPF DBD packets. Thus, use of this command allows the OSPF adjacency to reach the FULL state even though there is an interface MTU mismatch between two OSPF routers.

```
set protocols ospf interface <interface> network <type>
```

This command allows to specify the distribution type for the network connected to this interface:

broadcast – broadcast IP addresses distribution. **non-broadcast** – address distribution in NBMA networks topology. **point-to-multipoint** – address distribution in point-to-multipoint networks. **point-to-point** – address distribution in point-to-point networks.

```
set protocols ospf interface <interface> priority <number>
```

This command sets Router Priority integer value. The router with the highest priority will be more eligible to become Designated Router. Setting the value to 0, makes the router ineligible to become Designated Router. The default value is 1. The interval range is 0 to 255.

```
set protocols ospf interface <interface> retransmit-interval <number>
```

This command sets number of seconds for RxmtInterval timer value. This value is used when retransmitting Database Description and Link State Request packets if acknowledge was not received. The default value is 5 seconds. The interval range is 3 to 65535.

```
set protocols ospf interface <interface> transmit-delay <number>
```

This command sets number of seconds for InfTransDelay value. It allows to set and adjust for each interface the delay interval before starting the synchronizing process of the router's database with all neighbors. The default value is 1 seconds. The interval range is 3 to 65535.

Manual Neighbor Configuration

OSPF routing devices normally discover their neighbors dynamically by listening to the broadcast or multicast hello packets on the network. Because an NBMA network does not support broadcast (or multicast), the device cannot discover its neighbors dynamically, so you must configure all the neighbors statically.

```
set protocols ospf neighbor <A.B.C.D>
```

This command specifies the IP address of the neighboring device.

```
set protocols ospf neighbor <A.B.C.D> poll-interval <seconds>
```

This command specifies the length of time, in seconds, before the routing device sends hello packets out of the interface before it establishes adjacency with a neighbor. The range is 1 to 65535 seconds. The default value is 60 seconds.

```
set protocols ospf neighbor <A.B.C.D> priority <number>
```

This command specifies the router priority value of the nonbroadcast neighbor associated with the IP address specified. The default is 0. This keyword does not apply to point-to-multipoint interfaces.

Redistribution Configuration

```
set protocols ospf redistribute <route source>
```

This command redistributes routing information from the given route source to the OSPF process. There are five modes available for route source: bgp, connected, kernel, rip, static.

```
set protocols ospf default-metric <number>
```

This command specifies the default metric value of redistributed routes. The metric range is 0 to 16777214.

```
set protocols ospf redistribute <route source> metric <number>
```

This command specifies metric for redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, rip, static. The metric range is 1 to 16777214.

```
set protocols ospf redistribute <route source> metric-type <1|2>
```

This command specifies metric type for redistributed routes. Difference between two metric types that metric type 1 is a metric which is “commensurable” with inner OSPF links. When calculating a metric to the external destination, the full path metric is calculated as a metric sum path of a router which had advertised this link plus the link metric. Thus, a route with the least summary metric will be selected. If external link is advertised with metric type 2 the path is selected which lies through the router which advertised this link with the least metric despite of the fact that internal path to this router is longer (with more cost). However, if two routers advertised an external link and with metric type 2 the preference is given to the path which lies through the router with a shorter internal path. If two different routers advertised two links to the same external destination but with different metric type, metric type 1 is preferred. If type of a metric left undefined the router will consider these external links to have a default metric type 2.

```
set protocols ospf redistribute <route source> route-map <name>
```

This command allows to use route map to filter redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, rip, static.

Operational Mode Commands

```
show ip ospf neighbor
```

This command displays the neighbors status.

Neighbor ID	Pri	State	Dead Time	Address	Interface
	RXmtL	RqstL	DBsmL		
10.0.13.1	1	Full/DR	38.365s	10.0.13.1	eth0:10.0.13.3
	0	0	0		
10.0.23.2	1	Full/Backup	39.175s	10.0.23.2	eth1:10.0.23.3
	0	0	0		

```
show ip ospf neighbor detail
```

This command displays the neighbors information in a detailed form, not just a summary table.

```
Neighbor 10.0.13.1, interface address 10.0.13.1
  In the area 0.0.0.0 via interface eth0
  Neighbor priority is 1, State is Full, 5 state changes

  Thread Database Description Retransmission off
  Thread Link State Request Retransmission on
  Thread Link State Update Retransmission on

```

show ip ospf neighbor <A.B.C.D>

This command displays the neighbors information in a detailed form for a neighbor whose IP address is specified.

show ip ospf neighbor <intname>

This command displays the neighbors status for a neighbor on the specified interface.

show ip ospf interface [<intname>]

This command displays state and configuration of OSPF the specified interface, or all interfaces if no interface is given.

```

```

show ip ospf route

This command displays the OSPF routing table, as determined by the most recent SPF calculation.

```

===== OSPF network routing table =====
N IA 10.0.12.0/24      [3] area: 0.0.0.0
                        via 10.0.13.3, eth0
N   10.0.13.0/24      [1] area: 0.0.0.0
                        directly attached to eth0
N IA 10.0.23.0/24     [2] area: 0.0.0.0
                        via 10.0.13.3, eth0
N   10.0.34.0/24     [2] area: 0.0.0.0
                        via 10.0.13.3, eth0

===== OSPF router routing table =====
R   10.0.23.3          [1] area: 0.0.0.0, ABR
                        via 10.0.13.3, eth0
R   10.0.34.4          [2] area: 0.0.0.0, ASBR
                        via 10.0.13.3, eth0

===== OSPF external routing table =====
N E2 172.16.0.0/24    [2/20] tag: 0
                        via 10.0.13.3, eth0

```

The table consists of following data:

OSPF network routing table – includes a list of acquired routes for all accessible networks (or aggregated area ranges) of OSPF system. “IA” flag means that route destination is in the area to which the router is not connected, i.e. it’s an inter-area path. In square brackets a summary metric for all links through which a path lies to this network is specified. “via” prefix defines a router-gateway, i.e. the first router on the way to the destination (next hop). **OSPF router routing table** – includes a list of acquired routes to all accessible ABRs and ASBRs. **OSPF external routing table** – includes a list of acquired routes that are external to the OSPF process. “E” flag points to the external link metric type (E1 – metric type 1, E2 – metric type 2). External link metric is printed in the “<metric of the router which advertised the link>/<link metric>” format.

show ip ospf border-routers

This command displays a table of paths to area boundary and autonomous system boundary routers.

show ip ospf database

This command displays a summary table with a database contents (LSA).

```

OSPF Router with ID (10.0.13.1)

show ip ospf database <type> [A.B.C.D] [adv-router <A.B.C.D>|self-originate]

This command displays a database contents for a specific link advertisement type.

The type can be the following: asbr-summary, external, network, nssa-external, opaque-area, opaque-as, opaque-link, router, summary.

[A.B.C.D] – link-state-id. With this specified the command displays portion of the network environment that is being described by the advertisement. The value entered depends on the advertisement's LS type. It must be entered in the form of an IP address.

adv-router <A.B.C.D> – router id, which link advertisements need to be reviewed.

self-originate displays only self-originated LSAs from the local router.

```

      OSPF Router with ID (10.0.13.1)

      Router Link States (Area 0.0.0.0)

LS age: 1213
Options: 0x2 : *|-|-|-|-|E|-

Advertising Router: 10.0.13.1
LS Seq Number: 80000009
Checksum: 0xd119
Length: 36

Number of Links: 1

Link connected to: a Transit Network
(Link ID) Designated Router address: 10.0.13.1
(Link Data) Router Interface address: 10.0.13.1
Number of TOS metrics: 0
TOS 0 Metric: 1

```

show ip ospf database max-age

This command displays LSAs in MaxAge list.

Configuration Example

Below you can see a typical configuration using 2 nodes, redistribute loopback address and the node 1 sending the default route:

Node 1

```

set interfaces loopback lo address 10.1.1.1/32
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf default-information originate always
set protocols ospf default-information originate metric 10
set protocols ospf default-information originate metric-type 2
set protocols ospf log-adjacency-changes
set protocols ospf parameters router-id 10.1.1.1
set protocols ospf redistribute connected metric-type 2
set protocols ospf redistribute connected route-map CONNECT

set policy route-map CONNECT rule 10 action permit
set policy route-map CONNECT rule 10 match interface lo

```

Node 2

```

set interfaces loopback lo address 10.2.2.2/32
set protocols ospf area 0 network 192.168.0.0/24
set protocols ospf log-adjacency-changes
set protocols ospf parameters router-id 10.2.2.2
set protocols ospf redistribute connected metric-type 2
set protocols ospf redistribute connected route-map CONNECT

set policy route-map CONNECT rule 10 action permit
set policy route-map CONNECT rule 10 match interface lo

```

OSPFv3 (IPv6)

Configuration

General

VyOS does not have a special command to start the OSPFv3 process. The OSPFv3 process starts when the first ospf enabled interface is configured.

set protocols ospfv3 area <number> interface <interface>

This command specifies the OSPFv3 enabled interface. This command is also used to enable the OSPF process. The area number can be specified in decimal notation in the range from 0 to 4294967295. Or it can be specified in dotted decimal notation similar to ip address.

set protocols ospfv3 parameters router-id <rid>

This command sets the router-ID of the OSPFv3 process. The router-ID may be an IP address of the router, but need not be – it can be any arbitrary 32bit number. However it **MUST** be unique within the entire OSPFv3 domain to the OSPFv3 speaker – bad things will happen if multiple OSPFv3 speakers are configured with the same router-ID!

Optional

set protocols ospfv3 distance global <distance>

This command change distance value of OSPFv3 globally. The distance range is 1 to 255.

set protocols ospfv3 distance ospfv3 <external|inter-area|intra-area> <distance>

This command change distance value of OSPFv3. The arguments are the distance values for external routes, inter-area routes and intra-area routes respectively. The distance range is 1 to 255.

Area Configuration

```
set protocols ospfv3 area <number> range <prefix>
```

This command summarizes intra area paths from specified area into one Type-3 Inter-Area Prefix LSA announced to other areas. This command can be used only in ABR.

```
set protocols ospfv3 area <number> range <prefix> not-advertise
```

This command instead of summarizing intra area paths filter them - i.e. intra area paths from this range are not advertised into other areas. This command makes sense in ABR only.

Interface Configuration

```
set protocols ospfv3 interface <intname> ipv6 cost <number>
```

This command sets link cost for the specified interface. The cost value is set to router-LSA's metric field and used for SPF calculation. The cost range is 1 to 65535.

```
set protocols ospfv3 interface <intname> dead-interval <number>
```

Set number of seconds for router Dead Interval timer value used for Wait Timer and Inactivity Timer. This value must be the same for all routers attached to a common network. The default value is 40 seconds. The interval range is 1 to 65535.

```
set protocols ospfv3 interface <intname> hello-interval <number>
```

Set number of seconds for Hello Interval timer value. Setting this value, Hello packet will be sent every timer value seconds on the specified interface. This value must be the same for all routers attached to a common network. The default value is 10 seconds. The interval range is 1 to 65535.

```
set protocols ospfv3 interface <intname> mtu-ignore
```

This command disables check of the MTU value in the OSPF DBD packets. Thus, use of this command allows the OSPF adjacency to reach the FULL state even though there is an interface MTU mismatch between two OSPF routers.

```
set protocols ospfv3 interface <intname> network <type>
```

This command allows to specify the distribution type for the network connected to this interface:

broadcast – broadcast IP addresses distribution. **point-to-point** – address distribution in point-to-point networks.

```
set protocols ospfv3 interface <intname> priority <number>
```

This command sets Router Priority integer value. The router with the highest priority will be more eligible to become Designated Router. Setting the value to 0, makes the router ineligible to become Designated Router. The default value is 1. The interval range is 0 to 255.

```
set protocols ospfv3 interface <intname> passive
```

This command specifies interface as passive. Passive interface advertises its address, but does not run the OSPF protocol (adjacencies are not formed and hello packets are not generated).

```
set protocols ospfv3 interface <intname> retransmit-interval <number>
```

This command sets number of seconds for RxmtInterval timer value. This value is used when retransmitting Database Description and Link State Request packets if acknowledge was not received. The default value is 5 seconds. The interval range is 3 to 65535.

set protocols ospfv3 interface <intname> transmit-delay <number>

This command sets number of seconds for InfTransDelay value. It allows to set and adjust for each interface the delay interval before starting the synchronizing process of the router's database with all neighbors. The default value is 1 seconds. The interval range is 3 to 65535.

Redistribution Configuration

set protocols ospfv3 redistribute <route source>

This command redistributes routing information from the given route source to the OSPFv3 process. There are five modes available for route source: bgp, connected, kernel, ripng, static.

set protocols ospf redistribute <route source> route-map <name>

This command allows to use route map to filter redistributed routes from given route source. There are five modes available for route source: bgp, connected, kernel, ripng, static.

Operational Mode Commands

show ipv6 ospfv3 neighbor

This command displays the neighbors status.

show ipv6 ospfv3 neighbor detail

This command displays the neighbors information in a detailed form, not just a summary table.

show ipv6 ospfv3 neighbor drchoice

This command displays the neighbor DR choice information.

show ipv6 ospfv3 interface [prefix] [<intname> [prefix]]

This command displays state and configuration of OSPF the specified interface, or all interfaces if no interface is given. With the argument `prefix` this command shows connected prefixes to advertise.

show ipv6 ospfv3 route

This command displays the OSPF routing table, as determined by the most recent SPF calculation.

show ipv6 ospfv3 border-routers

This command displays a table of paths to area boundary and autonomous system boundary routers.

show ipv6 ospfv3 database

This command displays a summary table with a database contents (LSA).

show ipv6 ospfv3 database <type> [A.B.C.D] [adv-router <A.B.C.D>|self-originate]

This command displays a database contents for a specific link advertisement type.

show ipv6 ospfv3 redistribute

This command displays external information redistributed into OSPFv3

Configuration Example

A typical configuration using 2 nodes.

Node 1:

```
set protocols ospfv3 area 0.0.0.0 interface eth1
set protocols ospfv3 area 0.0.0.0 range 2001:db8:1::/64
set protocols ospfv3 parameters router-id 192.168.1.1
set protocols ospfv3 redistribute connected
```

Node 2:

```
set protocols ospfv3 area 0.0.0.0 interface eth1
set protocols ospfv3 area 0.0.0.0 range 2001:db8:2::/64
set protocols ospfv3 parameters router-id 192.168.2.1
set protocols ospfv3 redistribute connected
```

To see the redistributed routes:

```
show ipv6 ospfv3 redistribute
```

Note: You cannot easily redistribute IPv6 routes via OSPFv3 on a WireGuard interface link. This requires you to configure link-local addresses manually on the WireGuard interfaces, see [T1483](#).

Example configuration for WireGuard interfaces:

Node 1

```
set interfaces wireguard wg01 address 'fe80::216:3eff:fe51:fd8c/64'
set interfaces wireguard wg01 address '192.168.0.1/24'
set interfaces wireguard wg01 peer ospf02 allowed-ips '::/0'
set interfaces wireguard wg01 peer ospf02 allowed-ips '0.0.0.0/0'
set interfaces wireguard wg01 peer ospf02 endpoint '10.1.1.101:12345'
set interfaces wireguard wg01 peer ospf02 pubkey 'ie3...='
set interfaces wireguard wg01 port '12345'
set protocols ospfv3 parameters router-id 192.168.1.1
set protocols ospfv3 area 0.0.0.0 interface 'wg01'
set protocols ospfv3 area 0.0.0.0 interface 'lo'
```

Node 2

```

8.9.7 RIP

RIP (Routing Information Protocol) is a widely deployed interior gateway protocol. RIP was developed in the 1970s at Xerox Labs as part of the XNS routing protocol. RIP is a distance-vector protocol and is based on the Bellman-Ford algorithms. As a distance-vector protocol, RIP router send updates to its neighbors periodically, thus allowing the convergence to a known topology. In each update, the distance to any given network will be broadcast to its neighboring router.

Supported versions of RIP are:

- RIPv1 as described in [RFC 1058](#)
- RIPv2 as described in [RFC 2453](#)

General Configuration

set protocols rip network <A.B.C.D/M>

This command enables RIP and sets the RIP enable interface by NETWORK. The interfaces which have addresses matching with NETWORK are enabled.

set protocols rip interface <interface>

This command specifies a RIP enabled interface by interface name. Both the sending and receiving of RIP packets will be enabled on the port specified in this command.

set protocols rip neighbor <A.B.C.D>

This command specifies a RIP neighbor. When a neighbor doesn't understand multicast, this command is used to specify neighbors. In some cases, not all routers will be able to understand multicasting, where packets are sent to a network or a group of addresses. In a situation where a neighbor cannot process multicast packets, it is necessary to establish a direct link between routers.

set protocols rip passive-interface interface <interface>

This command sets the specified interface to passive mode. On passive mode interface, all receiving packets are processed as normal and VyOS does not send either multicast or unicast RIP packets except to RIP neighbors specified with neighbor command.

set protocols rip passive-interface interface default

This command specifies all interfaces to passive mode.

Optional Configuration

set protocols rip default-distance <distance>

This command change distance value of RIP. The distance range is 1 to 255.

Note: Routes with a distance of 255 are effectively disabled and not installed into the kernel.

set protocols rip network-distance <A.B.C.D/M> distance <distance>

This command sets default RIP distance to specified value when the route's source IP address matches the specified prefix.

set protocols rip network-distance <A.B.C.D/M> access-list <name>

This command can be used with previous command to sets default RIP distance to specified value when the route's source IP address matches the specified prefix and the specified access-list.

set protocols rip default-information originate

This command generate a default route into the RIP.

set protocols rip distribute-list access-list <in|out> <number>

This command can be used to filter the RIP path using access lists. `in` and `out` this is the direction in which the access lists are applied.

set protocols rip distribute-list interface <interface> access-list <in|out> <number>

This command allows you apply access lists to a chosen interface to filter the RIP path.

set protocols rip distribute-list prefix-list <in|out> <name>

This command can be used to filter the RIP path using prefix lists. `in` and `out` this is the direction in which the prefix lists are applied.

set protocols rip distribute-list interface <interface> prefix-list <in|out> <name>

This command allows you apply prefix lists to a chosen interface to filter the RIP path.

set protocols rip route <A.B.C.D/M>

This command is specific to FRR and VyOS. The route command makes a static route only inside RIP. This command should be used only by advanced users who are particularly knowledgeable about the RIP protocol. In most cases, we recommend creating a static route in VyOS and redistributing it in RIP using `redistribute static`.

set protocols rip timers update <seconds>

This command specifies the update timer. Every update timer seconds, the RIP process is awakened to send an unsolicited response message containing the complete routing table to all neighboring RIP routers. The time range is 5 to 2147483647. The default value is 30 seconds.

set protocols rip timers timeout <seconds>

This command specifies the timeout timer. Upon expiration of the timeout, the route is no longer valid; however, it is retained in the routing table for a short time so that neighbors can be notified that the route has been dropped. The time range is 5 to 2147483647. The default value is 180 seconds.

set protocols rip timers garbage-collection <seconds>

This command specifies the garbage-collection timer. Upon expiration of the garbage-collection timer, the route is finally removed from the routing table. The time range is 5 to 2147483647. The default value is 120 seconds.

Redistribution Configuration

set protocols rip redistribute <route source>

This command redistributes routing information from the given route source into the RIP tables. There are five modes available for route source: bgp, connected, kernel, ospf, static.

set protocols rip redistribute <route source> metric <metric>

This command specifies metric for redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, ospf, static. The metric range is 1 to 16.

set protocols rip redistribute <route source> route-map <name>

This command allows to use route map to filter redistributed routes from the given route source. There are five modes available for route source: bgp, connected, kernel, ospf, static.

set protocols rip default-metric <metric>

This command modifies the default metric (hop count) value for redistributed routes. The metric range is 1 to 16. The default value is 1. This command does not affect connected route even if it is redistributed by `redistribute connected`. To modify connected route's metric value, please use `redistribute connected metric`.

Interfaces Configuration

set interfaces <inttype> <intname> ip rip authentication plaintext-password <text>

This command sets the interface with RIP simple password authentication. This command also sets authentication string. The string must be shorter than 16 characters.

set interfaces <inttype> <intname> ip rip authentication md5 <id> password <text>

This command sets the interface with RIP MD5 authentication. This command also sets MD5 Key. The key must be shorter than 16 characters.

set interfaces <inttype> <intname> ip rip split-horizon disable

This command disables split-horizon on the interface. By default, VyOS does not advertise RIP routes out the interface over which they were learned (split horizon).

set interfaces <inttype> <intname> ip rip split-horizon poison-reverse

This command enables poison-reverse on the interface. If both poison reverse and split horizon are enabled, then VyOS advertises the learned routes as unreachable over the interface on which the route was learned.

Operational Mode Commands

show ip rip

This command displays RIP routes.

Codes: R - RIP, C - connected, S - Static, O - OSPF, B - BGP

Sub-codes:

(n) - normal, (s) - static, (d) - default, (r) - redistribute,
(i) - interface

Network	Next Hop	Metric From	Tag Time
---------	----------	-------------	----------

(continues on next page)

(continued from previous page)

C(i)	10.0.12.0/24	0.0.0.0	1 self	0
C(i)	10.0.13.0/24	0.0.0.0	1 self	0
R(n)	10.0.23.0/24	10.0.12.2	2 10.0.12.2	0 02:53

show ip rip status

The command displays current RIP status. It includes RIP timer, filtering, version, RIP enabled interface and RIP peer information.

```
Routing Protocol is "rip"
  Sending updates every 30 seconds with +/-50%, next due in 11 seconds
  Timeout after 180 seconds, garbage collect after 120 seconds
  Outgoing update filter list for all interface is not set
  Incoming update filter list for all interface is not set
  Default redistribution metric is 1
  Redistributing:
  Default version control: send version 2, receive any version
    Interface      Send  Recv  Key-chain
    eth0           2     1 2
    eth2           2     1 2
  Routing for Networks:
    10.0.12.0/24
    eth0
  Routing Information Sources:
    Gateway          BadPackets  BadRoutes  Distance  Last Update
    10.0.12.2         0           0         120      00:00:11
  Distance: (default is 120)
```

Configuration Example

Simple RIP configuration using 2 nodes and redistributing connected interfaces.

Node 1:

```
set interfaces loopback address 10.1.1.1/32
set protocols rip network 192.168.0.0/24
set protocols rip redistribute connected
```

Node 2:

```
set interfaces loopback address 10.2.2.2/32
set protocols rip network 192.168.0.0/24
set protocols rip redistribute connected
```

8.9.8 RPKI

There are two types of Network Admins who deal with BGP, those who have created an international incident and/or outage, and those who are lying

—tweet by EvilMog, 2020-02-21

RPKI (Resource Public Key Infrastructure) is a framework PKI (Public Key Infrastructure) designed to secure the Internet routing infrastructure. It associates BGP route announcements with the correct originating ASN which BGP routers can then use to check each route against the corresponding ROA (Route Origin Authorisation) for validity. RPKI is described in [RFC 6480](#).

A BGP-speaking router like VyOS can retrieve ROA information from RPKI “Relying Party software” (often just called an “RPKI server” or “RPKI validator”) by using RTR (RPKI to Router) protocol. There are several open source implementations to choose from, such as NLNetLabs’ [Routinator](#) (written in Rust), Cloudflare’s [GoRTR](#) and [OctoRPKI](#) (written in Go), and RIPE NCC’s [RPKI Validator](#) (written in Java). The RTR protocol is described in [RFC 8210](#).

Tip: If you are new to these routing security technologies then there is an [excellent guide to RPKI](#) by NLnet Labs which will get you up to speed very quickly. Their documentation explains everything from what RPKI is to deploying it in production. It also has some [help and operational guidance](#) including “What can I do about my route having an Invalid state?”

Getting started

First you will need to deploy an RPKI validator for your routers to use. The RIPE NCC helpfully provide [some instructions](#) to get you started with several different options. Once your server is running you can start validating announcements.

Imported prefixes during the validation may have values:

- valid** The prefix and ASN that originated it match a signed ROA. These are probably trustworthy route announcements.
- invalid** The prefix or prefix length and ASN that originated it doesn’t match any existing ROA. This could be the result of a prefix hijack, or merely a misconfiguration, but should probably be treated as untrustworthy route announcements.
- notfound** No ROA exists which covers that prefix. Unfortunately this is the case for about 80% of the IPv4 prefixes which were announced to the DFZ (default-free zone) at the start of 2020 (see more detail in NLnet Labs’ [RPKI analytics](#)).

Note: If you are responsible for the global addresses assigned to your network, please make sure that your prefixes have ROAs associated with them to avoid being *notfound* by RPKI. For most ASNs this will involve publishing ROAs via your RIR (Regional Internet Registry) (RIPE NCC, APNIC, ARIN, LACNIC or AFRINIC), and is something you are encouraged to do whenever you plan to announce addresses into the DFZ.

Particularly large networks may wish to run their own RPKI certificate authority and publication server instead of publishing ROAs via their RIR. This is a subject far beyond the scope of VyOS’ documentation. Consider reading about [Krill](#) if this is a rabbit hole you need or especially want to dive down.

Features of the Current Implementation

In a nutshell, the current implementation provides the following features:

- The BGP router can connect to one or more RPKI cache servers to receive validated prefix to origin AS mappings. Advanced failover can be implemented by server sockets with different preference values.
- If no connection to an RPKI cache server can be established after a pre-defined timeout, the router will process routes without prefix origin validation. It still will try to establish a connection to an RPKI cache server in the background.
- By default, enabling RPKI does not change best path selection. In particular, invalid prefixes will still be considered during best path selection. However, the router can be configured to ignore all invalid prefixes.

- Route maps can be configured to match a specific RPKI validation state. This allows the creation of local policies, which handle BGP routes based on the outcome of the Prefix Origin Validation.
- Updates from the RPKI cache servers are directly applied and path selection is updated accordingly. (Soft reconfiguration must be enabled for this to work).

Configuration

protocols rpki polling-period <1-86400>

Define the time interval to update the local cache

The default value is 300 seconds.

protocols rpki cache <address> port <port>

Defined the IPv4, IPv6 or FQDN and port number of the caching RPKI caching instance which is used.

This is a mandatory setting.

protocols rpki cache <address> preference <preference>

Multiple RPKI caching instances can be supplied and they need a preference in which their result sets are used.

This is a mandatory setting.

SSH

Connections to the RPKI caching server can not only be established by HTTP/TLS but you can also rely on a secure SSH session to the server. To enable SSH you first need to create yourself an SSH client keypair using `generate ssh client-key /config/auth/id_rsa_rpki`. Once your key is created you can setup the connection.

protocols rpki cache <address> ssh username <user>

SSH username to establish an SSH connection to the cache server.

protocols rpki cache <address> ssh known-hosts-file <filepath>

Local path that includes the known hosts file.

protocols rpki cache <address> ssh private-key-file <filepath>

Local path that includes the private key file of the router.

protocols rpki cache <address> ssh public-key-file <filepath>

Local path that includes the public key file of the router.

Note: When using SSH, known-hosts-file, private-key-file and public-key-file are mandatory options.

Example

We can build route-maps for import based on these states. Here is a simple RPKI configuration, where *routinator* is the RPKI-validating “cache” server with ip *192.0.2.1*:

```
set protocols rpki cache 192.0.2.1 port '3323'
set protocols rpki cache 192.0.2.1 preference '1'
```

Here is an example route-map to apply to routes learned at import. In this filter we reject prefixes with the state *invalid*, and set a higher *local-preference* if the prefix is RPKI *valid* rather than merely *notfound*.

```
set policy route-map ROUTES-IN rule 10 action 'permit'
set policy route-map ROUTES-IN rule 10 match rpki 'valid'
set policy route-map ROUTES-IN rule 10 set local-preference '300'
set policy route-map ROUTES-IN rule 20 action 'permit'
set policy route-map ROUTES-IN rule 20 match rpki 'notfound'
set policy route-map ROUTES-IN rule 20 set local-preference '125'
set policy route-map ROUTES-IN rule 30 action 'deny'
set policy route-map ROUTES-IN rule 30 match rpki 'invalid'
```

Once your routers are configured to reject RPKI-invalid prefixes, you can test whether the configuration is working correctly using the [RIPE Labs RPKI Test](#) experimental tool.

8.9.9 Static

Static routes are manually configured routes, which, in general, cannot be updated dynamically from information VyOS learns about the network topology from other routing protocols. However, if a link fails, the router will remove routes, including static routes, from the RIPB (Routing Information Base) that used this interface to reach the next hop. In general, static routes should only be used for very simple network topologies, or to override the behavior of a dynamic routing protocol for a small number of routes. The collection of all routes the router has learned from its configuration or from its dynamic routing protocols is stored in the RIB. Unicast routes are directly used to determine the forwarding table used for unicast packet forwarding.

Static Routes

set protocols static route <subnet> next-hop <address>

Configure next-hop <address> for an IPv4 static route. Multiple static routes can be created.

set protocols static route <subnet> next-hop <address> disable

Disable this IPv4 static route entry.

set protocols static route <subnet> next-hop <address> distance <distance>

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

Note: Routes with a distance of 255 are effectively disabled and not installed into the kernel.

set protocols static route6 <subnet> next-hop <address>

Configure next-hop <address> for an IPv6 static route. Multiple static routes can be created.

set protocols static route6 <subnet> next-hop <address> disable

Disable this IPv6 static route entry.

set protocols static route6 <subnet> next-hop <address> distance <distance>

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

Note: Routes with a distance of 255 are effectively disabled and not installed into the kernel.

Interface Routes

set protocols static route <subnet> interface <interface>

Allows you to configure the next-hop interface for an interface-based IPv4 static route. *<interface>* will be the next-hop interface where traffic is routed for the given *<subnet>*.

set protocols static route <subnet> interface <interface> disable

Disables interface-based IPv4 static route.

set protocols static route <subnet> interface <interface> distance <distance>

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

set protocols static route6 <subnet> interface <interface>

Allows you to configure the next-hop interface for an interface-based IPv6 static route. *<interface>* will be the next-hop interface where traffic is routed for the given *<subnet>*.

set protocols static route6 <subnet> interface <interface> disable

Disables interface-based IPv6 static route.

set protocols static route6 <subnet> interface <interface> distance <distance>

Defines next-hop distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Range is 1 to 255, default is 1.

Blackhole

set protocols static route <subnet> blackhole

Use this command to configure a “black-hole” route on the router. A black-hole route is a route for which the system silently discard packets that are matched. This prevents networks leaking out public interfaces, but it does not prevent them from being used as a more specific route inside your network.

set protocols static route <subnet> blackhole distance <distance>

Defines blackhole distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

set protocols static route6 <subnet> blackhole

Use this command to configure a “black-hole” route on the router. A black-hole route is a route for which the system silently discard packets that are matched. This prevents networks leaking out public interfaces, but it does not prevent them from being used as a more specific route inside your network.

set protocols static route6 <subnet> blackhole distance <distance>

Defines blackhole distance for this route, routes with smaller administrative distance are elected prior to those with a higher distance.

Alternate Routing Tables

TBD

Alternate routing tables are used with policy based routing by utilizing [VRF](#).

8.9.10 ARP

ARP (Address Resolution Protocol) is a communication protocol used for discovering the link layer address, such as a MAC address, associated with a given internet layer address, typically an IPv4 address. This mapping is a critical function in the Internet protocol suite. ARP was defined in 1982 by [RFC 826](#) which is Internet Standard STD 37.

In Internet Protocol Version 6 (IPv6) networks, the functionality of ARP is provided by the Neighbor Discovery Protocol (NDP).

To manipulate or display [ARP](#) table entries, the following commands are implemented.

Configure

set protocols static arp <address> hwaddr <mac>

This will configure a static ARP entry always resolving <address> to <mac>.

Example:

```
set protocols static arp 192.0.2.100 hwaddr 00:53:27:de:23:aa
```

Operation

show protocols static arp

Display all known ARP table entries spanning across all interfaces

```
vyos@vyos:~$ show protocols static arp
Address           HWtype  HWaddress           Flags Mask    Iface
10.1.1.1          ether   00:53:00:de:23:2e   C             eth1
10.1.1.100        ether   00:53:00:de:23:aa   CM            eth1
```

show protocols static arp interface eth1

Display all known ARP table entries on a given interface only (*eth1*):

```
vyos@vyos:~$ show protocols static arp interface eth1
Address           HWtype  HWaddress           Flags Mask    Iface
10.1.1.1          ether   00:53:00:de:23:2e   C             eth1
10.1.1.100        ether   00:53:00:de:23:aa   CM            eth1
```

8.10 Service

8.10.1 UDP Broadcast Relay

Certain vendors use broadcasts to identify their equipment within one ethernet segment. Unfortunately if you split your network with multiple VLANs you lose the ability of identifying your equipment.

This is where “UDP broadcast relay” comes into play! It will forward received broadcasts to other configured networks.

Every UDP port which will be forward requires one unique ID. Currently we support 99 IDs!

Configuration

set service broadcast-relay id <n> description <description>

A description can be added for each and every unique relay ID. This is useful to distinguish between multiple different ports/applications.

set service broadcast-relay id <n> interface <interface>

The interface used to receive and relay individual broadcast packets. If you want to receive/relay packets on both *eth1* and *eth2* both interfaces need to be added.

set service broadcast-relay id <n> port <port>

The UDP port number used by your application. It is mandatory for this kind of operation.

set service broadcast-relay id <n> disable

Each broadcast relay instance can be individually disabled without deleting the configured node by using the following command:

set service broadcast-relay disable

In addition you can also disable the whole service without the need to remove it from the current configuration.

Note: You can run the UDP broadcast relay service on multiple routers connected to a subnet. There is **NO** UDP broadcast relay packet storm!

Example

To forward all broadcast packets received on *UDP port 1900* on *eth3*, *eth4* or *eth5* to all other interfaces in this configuration.

```
set service broadcast-relay id 1 description 'SONOS'
set service broadcast-relay id 1 interface 'eth3'
set service broadcast-relay id 1 interface 'eth4'
set service broadcast-relay id 1 interface 'eth5'
set service broadcast-relay id 1 port '1900'
```

8.10.2 Conntrack Sync

One of the important features built on top of the Netfilter framework is connection tracking. Connection tracking allows the kernel to keep track of all logical network connections or sessions, and thereby relate all of the packets which may make up that connection. NAT relies on this information to translate all related packets in the same way, and iptables can use this information to act as a stateful firewall.

The connection state however is completely independent of any upper-level state, such as TCP's or SCTP's state. Part of the reason for this is that when merely forwarding packets, i.e. no local delivery, the TCP engine may not necessarily be invoked at all. Even connectionless-mode transmissions such as UDP, IPsec (AH/ESP), GRE and other tunneling protocols have, at least, a pseudo connection state. The heuristic for such protocols is often based upon a preset timeout value for inactivity, after whose expiration a Netfilter connection is dropped.

Each Netfilter connection is uniquely identified by a (layer-3 protocol, source address, destination address, layer-4 protocol, layer-4 key) tuple. The layer-4 key depends on the transport protocol; for TCP/UDP it is the port numbers, for tunnels it can be their tunnel ID, but otherwise is just zero, as if it were not part of the tuple. To be able to inspect the TCP port in all cases, packets will be mandatorily defragmented.

It is possible to use either Multicast or Unicast to sync conntrack traffic. Most examples below show Multicast, but unicast can be specified by using the “peer” keywork after the specified interface, as in the following example:

```
set service conntrack-sync interface eth0 peer 192.168.0.250
```

Configuration

set service conntrack-sync accept-protocol

Accept only certain protocols: You may want to replicate the state of flows depending on their layer 4 protocol.

Protocols are: tcp, sctp, dccp, udp, icmp and ipv6-icmp.

set service conntrack-sync event-listen-queue-size <size>

The daemon doubles the size of the netlink event socket buffer size if it detects netlink event message dropping. This clause sets the maximum buffer size growth that can be reached.

Queue size for listening to local conntrack events in MB.

set service conntrack-sync expect-sync <all|ftp|h323|nfs|sip|sqlnet>

Protocol for which expect entries need to be synchronized.

set service conntrack-sync failover-mechanism vrrp sync-group <group>

Failover mechanism to use for conntrack-sync.

Only VRRP is supported. Required option.

set service conntrack-sync ignore-address <x.x.x.x>

IP addresses or networks for which local conntrack entries will not be synced

set service conntrack-sync interface <name>

Interface to use for syncing conntrack entries.

set service conntrack-sync mcast-group <x.x.x.x>

Multicast group to use for syncing conntrack entries.

Defaults to 225.0.0.50.

set service conntrack-sync interface <name> peer <address>

Peer to send unicast UDP conntrack sync entries to, if not using Multicast configuration from above above.

set service conntrack-sync sync-queue-size <size>

Queue size for syncing conntrack entries in MB.

Operation

show conntrack table ipv4

Make sure conntrack is enabled by running and show connection tracking table.

```
vyos@vyos:~$ show conntrack table ipv4
TCP state codes: SS - SYN SENT, SR - SYN RECEIVED, ES - ESTABLISHED,
                  FW - FIN WAIT, CW - CLOSE WAIT, LA - LAST ACK,
                  TW - TIME WAIT, CL - CLOSE, LI - LISTEN
```

CONN ID	Source	Destination	Protocol	TIMEOUT
1015736576	10.35.100.87:58172	172.31.20.12:22	tcp [6] ES	430279
1006235648	10.35.101.221:57483	172.31.120.21:22	tcp [6] ES	413310
1006237088	10.100.68.100	172.31.120.21	icmp [1]	29
1015734848	10.35.100.87:56282	172.31.20.12:22	tcp [6] ES	300
1015734272	172.31.20.12:60286	239.10.10.14:694	udp [17]	29
1006239392	10.35.101.221	172.31.120.21	icmp [1]	29

Note: If the table is empty and you have a warning message, it means conntrack is not enabled. To enable conntrack, just create a NAT or a firewall rule. set firewall state-policy established action accept

show conntrack-sync external-cache

Show connection syncing external cache entries

show conntrack-sync internal-cache

Show connection syncing internal cache entries

show conntrack-sync statistics

Retrieve current statistics of connection tracking subsystem.

```
vyos@vyos:~$ show conntrack-sync statistics
Main Table Statistics:

cache internal:
current active connections:      19606
connections created:             6298470    failed:      0
connections updated:            3786793    failed:      0
connections destroyed:          6278864    failed:      0

cache external:
current active connections:      15771
connections created:            1660193    failed:      0
connections updated:            77204     failed:      0
connections destroyed:          1644422    failed:      0

traffic processed:
                                0 Bytes      0 Pckts

multicast traffic (active device=eth0.5):
    976826240 Bytes sent      212898000 Bytes recv
    8302333 Pckts sent       2009929 Pckts recv
    0 Error send             0 Error recv

message tracking:
    0 Malformed msgs        263 Lost msgs
```

show conntrack-sync status

Retrieve current status of connection tracking subsystem.

```
vyos@vyos:~$ show conntrack-sync status
sync-interface      : eth0.5
failover-mechanism  : vrrp [sync-group GEFOEKOM]
last state transition : no transition yet!
ExpectationSync     : disabled
```

Example

The next example is a simple configuration of conntrack-sync.

Now configure conntrack-sync service on router1 **and** router2

```
set high-availability vrrp group internal virtual-address ... etc ...
set high-availability vrrp sync-group syncgrp member 'internal'
set service conntrack-sync accept-protocol 'tcp'
set service conntrack-sync accept-protocol 'udp'
set service conntrack-sync accept-protocol 'icmp'
set service conntrack-sync failover-mechanism vrrp sync-group 'syncgrp'
set service conntrack-sync interface 'eth0'
set service conntrack-sync mcast-group '225.0.0.50'
```

On the active router, you should have information in the internal-cache of conntrack-sync. The same current active connections number should be shown in the external-cache of the standby router

On active router run:

```
$ show conntrack-sync statistics
```

Main Table Statistics:

cache internal:

current active connections:	10		
connections created:	8517	failed:	0
connections updated:	127	failed:	0
connections destroyed:	8507	failed:	0

cache external:

current active connections:	0		
connections created:	0	failed:	0
connections updated:	0	failed:	0
connections destroyed:	0	failed:	0

traffic processed:

0 Bytes	0 Pkts
---------	--------

multicast traffic (active device=eth0):

868780 Bytes sent	224136 Bytes recv
20595 Pkts sent	14034 Pkts recv
0 Error send	0 Error recv

message tracking:

0 Malformed msgs	0 Lost msgs
------------------	-------------

On standby router run:

```
$ show conntrack-sync statistics
```

Main Table Statistics:

cache internal:

current active connections:	0		
connections created:	0	failed:	0
connections updated:	0	failed:	0
connections destroyed:	0	failed:	0

cache external:

current active connections:	10		
connections created:	888	failed:	0
connections updated:	134	failed:	0
connections destroyed:	878	failed:	0

traffic processed:

0 Bytes	0 Pkts
---------	--------

multicast traffic (active device=eth0):

234184 Bytes sent	907504 Bytes recv
14663 Pkts sent	21495 Pkts recv
0 Error send	0 Error recv

message tracking:

0 Malformed msgs	0 Lost msgs
------------------	-------------

8.10.3 Console Server

Starting of with VyOS 1.3 (equuleus) we added support for running VyOS as an Out-of-Band Management device which provides remote access by means of SSH to directly attached serial interfaces.

Serial interfaces can be any interface which is directly connected to the CPU or chipset (mostly known as a ttyS interface in Linux) or any other USB to serial converter (Prolific PL2303 or FTDI FT232/FT4232 based chips).

If you happened to use a Cisco NM-16A - Sixteen Port Async Network Module or NM-32A - Thirty-two Port Async Network Module - this is your VyOS replacement.

For USB port information please refer to: [USB](#).

Configuration

Between computers, the most common configuration used was “8N1”: eight bit characters, with one start bit, one stop bit, and no parity bit. Thus 10 Baud times are used to send a single character, and so dividing the signalling bit-rate by ten results in the overall transmission speed in characters per second. This is also the default setting if none of those options are defined.

```
set service console-server <device> data-bits [7 | 8]
```

Configure either seven or eight data bits. This defaults to eight data bits if left unconfigured.

```
set service console-server <device> description <string>
```

A user friendly description identifying the connected peripheral.

```
set service console-server <device> parity [even | odd | none]
```

Set the parity option for the console. If unset this will default to none.

```
set service console-server <device> stop-bits [1 | 2]
```

Configure either one or two stop bits. This defaults to one stop bits if left unconfigured.

```
set service console-server <device> speed [ 300 | 1200 | 2400 | 4800 | 9600 |
19200 | 38400 | 57600 | 115200 ]
```

Note: USB to serial converters will handle most of their work in software so you should be careful with the selected baudrate as some times they can't cope with the expected speed.

Remote Access

Each individual configured console-server device can be directly exposed to the outside world. A user can directly connect via SSH to the configured port.

```
set service console-server <device> ssh port <port>
```

Accept SSH connections for the given *<device>* on TCP port *<port>*. After successful authentication the user will be directly dropped to the connected serial device.

Hint: Multiple users can connect to the same serial device but only one is allowed to write to the console port.

Operation

show console-server ports

Show configured serial ports and their respective interface configuration.

```
vyos@vyos:~$ show console-server ports
usb0b2.4p1.0          on /dev/serial/by-bus/usb0b2.4p1.0@ at 9600n
```

show console-server user

Show currently connected users.

```
vyos@vyos:~$ show console-server user
usb0b2.4p1.0          up  vyos@localhost
```

connect console <device>

Locally connect to serial port identified by <device>.

```
vyos@vyos-r1:~$ connect console usb0b2.4p1.0
[Enter `^Ec?' for help]
[-- MOTD -- VyOS Console Server]

vyos-r2 login:
```

Hint: Multiple users can connect to the same serial device but only one is allowed to write to the console port.

Hint: The sequence ^Ec? translates to: Ctrl+E c ?. To quit the session use: Ctrl+E c .

8.10.4 DHCP Relay

If you want your router to forward DHCP requests to an external DHCP server you can configure the system to act as a DHCP relay agent. The DHCP relay agent works with IPv4 and IPv6 addresses.

All interfaces used for the DHCP relay must be configured.

IPv4 relay

Configuration

set service dhcp-relay interface <interface>

Enable the DHCP relay service on the given interface.

set service dhcp-relay server <server>

Configure IP address of the DHCP <server> which will handle the relayed packets.

set service dhcp-relay relay-options relay-agents-packets discard

The router should discard DHCP packages already containing relay agent information to ensure that only requests from DHCP clients are forwarded.

Options

set service dhcp-relay relay-options hop-count <count>

Set the maximum hop <count> before packets are discarded. Range 0...255, default 10.

set service dhcp-relay relay-options max-size <size>

Set maximum <size> of DHCP packets including relay agent information. If a DHCP packet size surpasses this value it will be forwarded without appending relay agent information. Range 64...1400, default 576.

set service dhcp-relay relay-options relay-agents-packet <append | discard | forward | replace>

Four policies for reforwarding DHCP packets exist:

- **append:** The relay agent is allowed to append its own relay information to a received DHCP packet, disregarding relay information already present in the packet.
- **discard:** Received packets which already contain relay information will be discarded.
- **forward:** All packets are forwarded, relay information already present will be ignored.
- **replace:** Relay information already present in a packet is stripped and replaced with the router's own relay information set.

Example

- Listen for DHCP requests on interface eth1.
- DHCP server is located at IPv4 address 10.0.1.4.
- Router receives DHCP client requests on eth1 and relays them to the server at 10.0.1.4.

Fig. 3: DHCP relay example

The generated configuration will look like:

```
show service dhcp-relay
  interface eth1
  server 10.0.1.4
```

(continues on next page)

(continued from previous page)

```
relay-options {  
    relay-agents-packets discard  
}
```

Operation

restart dhcp relay-agent

Restart DHCP relay service

IPv6 relay

Configuration

set service dhcpv6-relay listen-interface <interface>

Set eth1 to be the listening interface for the DHCPv6 relay.

Multiple interfaces may be specified.

set service dhcpv6-relay upstream-interface <interface> address <server>

Specifies an upstream network <interface> from which replies from <server> and other relay agents will be accepted.

Options

set service dhcpv6-relay max-hop-count 'count'

Set maximum hop count before packets are discarded, default: 10

set service dhcpv6-relay use-interface-id-option

If this is set the relay agent will insert the interface ID. This option is set automatically if more than one listening interfaces are in use.

Example

- DHCPv6 requests are received by the router on *listening interface* eth1
- Requests are forwarded through eth2 as the *upstream interface*
- External DHCPv6 server is at 2001:db8::4

The generated configuration will look like:

```
commit  
show service dhcpv6-relay  
    listen-interface eth1 {  
    }  
    upstream-interface eth2 {  
        address 2001:db8::4  
    }
```

Fig. 4: DHCPv6 relay example

Operation

restart dhcpv6 relay-agent

Restart DHCPv6 relay agent immediately.

8.10.5 DHCP Server

VyOS uses ISC DHCP server for both IPv4 and IPv6 address assignment.

IPv4 server

The network topology is declared by shared-network-name and the subnet declarations. The DHCP service can serve multiple shared networks, with each shared network having 1 or more subnets. Each subnet must be present on an interface. A range can be declared inside a subnet to define a pool of dynamic addresses. Multiple ranges can be defined and can contain holes. Static mappings can be set to assign “static” addresses to clients based on their MAC address.

Configuration

```
set service dhcp-server shared-network-name <name> authoritative
```

This says that this device is the only DHCP server for this network. If other devices are trying to offer DHCP leases, this machine will send ‘DHCPNAK’ to any device trying to request an IP address that is not valid for this network.

```
set service dhcp-server shared-network-name <name> subnet <subnet>  
default-router <address>
```

This is a configuration parameter for the <subnet>, saying that as part of the response, tell the client that the default gateway can be reached at <address>.

```
set service dhcp-server shared-network-name <name> subnet <subnet> dns-server  
<address>
```

This is a configuration parameter for the subnet, saying that as part of the response, tell the client that the DNS server can be found at *<address>*.

Multiple DNS servers can be defined.

```
set service dhcp-server shared-network-name <name> subnet <subnet> lease
<time>
```

Assign the IP address to this machine for *<time>* seconds.

The default value is 86400 seconds which corresponds to one day.

```
set service dhcp-server shared-network-name <name> subnet <subnet> range <n>
start <address>
```

Create DHCP address range with a range id of *<n>*. DHCP leases are taken from this pool. The pool starts at address *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> range <n>
stop <address>
```

Create DHCP address range with a range id of *<n>*. DHCP leases are taken from this pool. The pool stops with address *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet> exclude
<address>
```

Always exclude this address from any defined range. This address will never be assigned by the DHCP server.

This option can be specified multiple times.

```
set service dhcp-server shared-network-name <name> subnet <subnet> domain-name
<domain-name>
```

The domain-name parameter should be the domain name that will be appended to the client's hostname to form a fully-qualified domain-name (FQDN) (DHCP Option 015).

```
set service dhcp-server shared-network-name <name> subnet <subnet>
domain-search <domain-name>
```

The domain-name parameter should be the domain name used when completing DNS request where no full FQDN is passed. This option can be given multiple times if you need multiple search domains (DHCP Option 119).

Failover

VyOS provides support for DHCP failover. DHCP failover must be configured explicitly by the following statements.

```
set service dhcp-server shared-network-name <name> subnet <subnet> failover
local-address <address>
```

Local IP *<address>* used when communicating to the failover peer.

```
set service dhcp-server shared-network-name <name> subnet <subnet> failover
peer-address <address>
```

Remote peer IP *<address>* of the second DHCP server in this failover cluster.

```
set service dhcp-server shared-network-name <name> subnet <subnet> failover
name <name>
```

A generic *<name>* referencing this sync service.

Note: *<name>* must be identical on both sides!

```
set service dhcp-server shared-network-name <name> subnet <subnet> failover
status <primary | secondary>
```

The primary and secondary statements determines whether the server is primary or secondary.

Note: In order for the primary and the secondary DHCP server to keep their lease tables in sync, they must be able to reach each other on TCP port 647. If you have firewall rules in effect, adjust them accordingly.

Hint: The dialogue between failover partners is neither encrypted nor authenticated. Since most DHCP servers exist within an organisation's own secure Intranet, this would be an unnecessary overhead. However, if you have DHCP failover peers whose communications traverse insecure networks, then we recommend that you consider the use of VPN tunneling between them to ensure that the failover partnership is immune to disruption (accidental or otherwise) via third parties.

Static mappings

You can specify a static DHCP assignment on a per host basis. You will need the MAC address of the station and your desired IP address. The address must be inside the subnet definition but can be outside of the range statement.

```
set service dhcp-server shared-network-name <name> subnet <subnet>
static-mapping <description> mac-address <address>
```

Create a new DHCP static mapping named *<description>* which is valid for the host identified by its MAC *<address>*.

```
set service dhcp-server shared-network-name <name> subnet <subnet>
static-mapping <description> ip-address <address>
```

Static DHCP IP address assign to host identified by *<description>*. IP address must be inside the *<subnet>* which is defined but can be outside the dynamic range created with `set service dhcp-server shared-network-name <name> subnet <subnet> range <n>`. If no ip-address is specified, an IP from the dynamic pool is used.

This is useful, for example, in combination with hostfile update.

Hint: This is the equivalent of the host block in dhcpd.conf of isc-dhcpd.

Options

Setting name	Option number	ISC-DHCP name	Option	Option description	Multi
client-prefix-length	1	subnet-mask		Specifies the clients subnet mask as per RFC 950. If unset, subnet declaration is used.	N
time-offset	2	time-offset		Offset of the client's subnet in seconds from Coordinated Universal Time (UTC)	N
default-router	3	routers		IPv4 address of router on the client's subnet	N
time-server	4	time-servers		RFC 868 time server IPv4 address	Y
dns-server	6	domain-name-servers		DNS server IPv4 address	Y
domain-name	15	domain-name		Client domain name	Y
ip-forwarding	19	ip-forwarding		Enable IP forwarding on client	N
ntp-server	42	ntp-servers		IP address of NTP server	Y
wins-server	44	netbios-name-servers		NetBIOS over TCP/IP name server	Y
server-identifier	54	dhcp-server-identifier		IP address for DHCP server identifier	N
bootfile-server	siaddr	next-server		IPv4 address of next bootstrap server	N
tftp-server-name	66	tftp-server-name		Name or IPv4 address of TFTP server	N
bootfile-name	67	bootfile-name, file-name		Bootstrap file name	N
smtp-server	69	smtp-server		IP address of SMTP server	Y
pop-server	70	pop-server		IP address of POP3 server	Y
domain-search	119	domain-search		Client domain search	Y
static-route	121, 249	rfc3442-static-route, windows-static-route		Classless static route	N
wpad-url	252	wpad-url, wpad-url code 252 = text		Web Proxy Autodiscovery (WPAD) URL	N
lease		default-lease-time, max-lease-time		Lease timeout in seconds (default: 86400)	N
range		range		DHCP lease range	Y
exclude				IP address to exclude from DHCP lease range	Y
failover				DHCP failover parameters	
static-mapping				Name of static mapping	Y

Multi: can be specified multiple times.

Raw Parameters

Raw parameters can be passed to shared-network-name, subnet and static-mapping:

```
set service dhcp-server shared-network-name <name> shared-network-parameters
  <text>          Additional shared-network parameters for DHCP server.
set service dhcp-server shared-network-name <name> subnet <subnet> subnet-parameters
  <text>          Additional subnet parameters for DHCP server.
set service dhcp-server shared-network-name <name> subnet <subnet> static-mapping
↳<description> static-mapping-parameters
  <text>          Additional static-mapping parameters for DHCP server.
                    Will be placed inside the "host" block of the mapping.
```

These parameters are passed as-is to isc-dhcp's dhcpd.conf under the configuration node they are defined in. They are not validated so an error in the raw parameters won't be caught by vyos's scripts and will cause dhcpd to fail to start. Always verify that the parameters are correct before committing the configuration. Refer to isc-dhcp's dhcpd.conf manual for more information: <https://kb.isc.org/docs/isc-dhcp-44-manual-pages-dhcpdconf>

Quotes can be used inside parameter values by replacing all quote characters with the string ". They will be replaced with literal quote characters when generating dhcpd.conf.

Example

Please see the *DHCP/DNS quick-start* configuration.

Failover

Configuration of a DHCP failover pair

- Setup DHCP failover for network 192.0.2.0/24
- Default gateway and DNS server is at 192.0.2.254
- The primary DHCP server uses address 192.168.189.252
- The secondary DHCP server uses address 192.168.189.253
- DHCP range spans from 192.168.189.10 - 192.168.189.250

Common configuration, valid for both primary and secondary node.

```
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 default-
↳router '192.0.2.254'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 dns-server
↳'192.0.2.254'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 domain-name
↳'vyos.net'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 range 0_
↳start '192.0.2.10'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 range 0 stop
↳'192.0.2.250'
```

Primary

```
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↳local-address '192.168.189.252'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↳name 'NET-VYOS'
```

(continues on next page)

(continued from previous page)

```
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪peer-address '192.168.189.253'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪status 'primary'
```

Secondary

```
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪local-address '192.168.189.253'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪name 'NET-VYOS'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪peer-address '192.168.189.252'
set service dhcp-server shared-network-name NET-VYOS subnet 192.0.2.0/24 failover_
↪status 'secondary'
```

Raw Parameters

- Override static-mapping's dns-server with a custom one that will be sent only to this host.
- An option that takes a quoted string is set by replacing all quote characters with the string " inside the static-mapping-parameters value. The resulting line in dhcpd.conf will be option pxelinux.configfile "pxelinux.cfg/01-00-15-17-44-2d-aa";.

```
set service dhcp-server shared-network-name dhcpexample subnet 192.0.2.0/24 static-
↪mapping example static-mapping-parameters "option domain-name-servers 192.0.2.11,
↪192.0.2.12;"
set service dhcp-server shared-network-name dhcpexample subnet 192.0.2.0/24 static-
↪mapping example static-mapping-parameters "option pxelinux.configfile &quot;
↪pxelinux.cfg/01-00-15-17-44-2d-aa&quot;;"
```

Option 43 for UniFI

- These parameters need to be part of the DHCP global options. They stay unchanged.

```
set service dhcp-server global-parameters 'option space ubnt;'
set service dhcp-server global-parameters 'option ubnt.unifi-address code 1 = ip-
↪address;'
set service dhcp-server global-parameters 'class &quot;ubnt&quot;; {'
set service dhcp-server global-parameters 'match if substring (option vendor-class-
↪identifier, 0, 4) = &quot;ubnt&quot;;'
set service dhcp-server global-parameters 'option vendor-class-identifier &quot;ubnt&
↪quot;;'
set service dhcp-server global-parameters 'vendor-option-space ubnt;'
set service dhcp-server global-parameters '}'
```

- Now we add the option to the scope, adapt to your setup

```
set service dhcp-server shared-network-name example-scope subnet 10.1.1.0/24 subnet-
↪parameters 'option ubnt.unifi-address 172.16.1.10;'
```

Operation Mode

restart dhcp server

Restart the DHCP server

show dhcp server statistics

Show the DHCP server statistics:

```
vyos@vyos:~$ show dhcp server statistics
Pool          Size      Leases    Available  Usage
-----
dhcpexample   99         2          97        2%
```

show dhcp server statistics pool <pool>

Show the DHCP server statistics for the specified pool.

show dhcp server leases

Show statuses of all active leases:

```
vyos@vyos:~$ show dhcp server leases
IP address      Hardware address  State      Lease start      Lease expiration
↳ Remaining    Pool              Hostname
-----
↳ -----
192.0.2.104     00:53:01:dd:ee:ff active      2019/12/05 14:24:23 2019/12/06 02:24:23
↳ 6:05:35      dhcpexample test1
192.0.2.115     00:53:01:ae:af:bf active      2019/12/05 18:02:37 2019/12/06 06:02:37
↳ 9:43:49      dhcpexample test2
```

Hint: Static mappings aren't shown. To show all states, use `show dhcp server leases state all`.

show dhcp server leases pool <pool>

Show only leases in the specified pool.

show dhcp server leases sort <key>

Sort the output by the specified key. Possible keys: ip, hardware_address, state, start, end, remaining, pool, hostname (default = ip)

show dhcp server leases state <state>

Show only leases with the specified state. Possible states: all, active, free, expired, released, abandoned, reset, backup (default = active)

IPv6 server

VyOS also provides DHCPv6 server functionality which is described in this section.

Configuration

set service dhcpv6-server preference <preference value>

Clients receiving advertise messages from multiple servers choose the server with the highest preference value. The range for this value is 0...255.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
lease-time {default | maximum | minimum}
```

The default lease time for DHCPv6 leases is 24 hours. This can be changed by supplying a `default-time`, `maximum-time` and `minimum-time`. All values need to be supplied in seconds.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
nis-domain <domain-name>
```

A NIS (Network Information Service) domain can be set to be used for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
nisplus-domain <domain-name>
```

The procedure to specify a NIS+ (Network Information Service Plus) domain is similar to the NIS domain one:

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
nis-server <address>
```

Specify a NIS server address for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
nisplus-server <address>
```

Specify a NIS+ server address for DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
sip-server <address | fqdn>
```

Specify a SIP (Session Initiation Protocol) server by IPv6 address of Fully Qualified Domain Name for all DHCPv6 clients.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
sntp-server-address <address>
```

A SNTP server address can be specified for DHCPv6 clients.

Prefix Delegation

To hand out individual prefixes to your clients the following configuration is used:

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
prefix-delegation start <address> prefix-length <length>
```

Hand out prefixes of size *<length>* to clients in subnet *<prefix>* when they request for prefix delegation.

```
set service dhcpv6-server shared-network-name <name> subnet <prefix>
prefix-delegation start <address> stop <address>
```

Delegate prefixes from the range indicated by the start and stop qualifier.

Address pools

DHCPv6 address pools must be configured for the system to act as a DHCPv6 server. The following example describes a common scenario.

Example:

- A shared network named NET1 serves subnet 2001:db8::/64

- It is connected to eth1
- DNS server is located at 2001:db8::ffff
- Address pool shall be 2001:db8::100 through 2001:db8::199.
- Lease time will be left at the default value which is 24 hours

```
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 address-
↪range start 2001:db8::100 stop 2001:db8::199
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 name-server_
↪2001:db8::ffff
```

The configuration will look as follows:

```
show service dhcpv6-server
  shared-network-name NET1 {
    subnet 2001:db8::/64 {
      address-range {
        start 2001:db8::100 {
          stop 2001:db8::199
        }
      }
      name-server 2001:db8::ffff
    }
  }
```

Static mappings

In order to map specific IPv6 addresses to specific hosts static mappings can be created. The following example explains the process.

Example:

- IPv6 address 2001:db8::101 shall be statically mapped
- IPv6 prefix 2001:db8:0:101::/64 shall be statically mapped
- Host specific mapping shall be named client1

Hint: The identifier is the device's DUID: colon-separated hex list (as used by isc-dhcp option dhcpv6.client-id). If the device already has a dynamic lease from the DHCPv6 server, its DUID can be found with `show service dhcpv6 server leases`. The DUID begins at the 5th octet (after the 4th colon) of IAID_DUID.

```
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-
↪mapping client1 ipv6-address 2001:db8::101
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-
↪mapping client1 ipv6-prefix 2001:db8:0:101::/64
set service dhcpv6-server shared-network-name 'NET1' subnet 2001:db8::/64 static-
↪mapping client1 identifier 00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff
```

The configuration will look as follows:

```
show service dhcp-server shared-network-name NET1
  shared-network-name NET1 {
    subnet 2001:db8::/64 {
```

(continues on next page)

(continued from previous page)

```

name-server 2001:db8:111::111
address-range {
    start 2001:db8::100 {
        stop 2001:db8::199 {
            }
        }
    }
static-mapping client1 {
    ipv6-address 2001:db8::101
    identifier 00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff
}
}
}

```

Operation Mode

restart dhcpv6 server

To restart the DHCPv6 server

show dhcpv6 server status

To show the current status of the DHCPv6 server.

show dhcpv6 server leases

Show statuses of all assigned leases:

```

vyos@vyos:~$ show dhcpv6 server leases
IPv6 address  State    Last communication    Lease expiration    Remaining    Type
↪           Pool      IAID_DUID
-----
↪-----
2001:db8::101  active  2019/12/05 19:40:10    2019/12/06 07:40:10    11:45:21    non-
↪temporary    NET1    98:76:54:32:00:01:00:01:12:34:56:78:aa:bb:cc:dd:ee:ff
2001:db8::102  active  2019/12/05 14:01:23    2019/12/06 02:01:23    6:06:34     non-
↪temporary    NET1    87:65:43:21:00:01:00:01:11:22:33:44:fa:fb:fc:fd:fe:ff

```

Hint: Static mappings aren't shown. To show all states, use `show dhcp server leases state all`.

show dhcpv6 server leases pool <pool>

Show only leases in the specified pool.

show dhcpv6 server leases sort <key>

Sort the output by the specified key. Possible keys: expires, iaid_duid, ip, last_comm, pool, remaining, state, type (default = ip)

show dhcpv6 server leases state <state>

Show only leases with the specified state. Possible states: abandoned, active, all, backup, expired, free, released, reset (default = active)

8.10.6 DNS Forwarding

Configuration

VyOS provides DNS infrastructure for small networks. It is designed to be lightweight and have a small footprint, suitable for resource constrained routers and firewalls. For this we utilize PowerDNS recursor.

The VyOS DNS forwarder does not require an upstream DNS server. It can serve as a full recursive DNS server - but it can also forward queries to configurable upstream DNS servers. By not configuring any upstream DNS servers you also avoid being tracked by the provider of your upstream DNS server.

set service dns forwarding system

Forward incoming DNS queries to the DNS servers configured under the `system name-server` nodes.

set service dns forwarding name-server <address>

Send all DNS queries to the IPv4/IPv6 DNS server specified under `<address>`. You can configure multiple nameservers here.

set service dns forwarding domain <domain-name> server <address>

Forward received queries for a particular domain (specified via `domain-name`) to a given nameserver. Multiple nameservers can be specified. You can use this feature for a DNS split-horizon configuration.

Note: This also works for reverse-lookup zones (`18.172.in-addr.arpa`).

set service dns forwarding allow-from <network>

Given the fact that open DNS recursors could be used on DDoS amplification attacks, you must configure the networks which are allowed to use this recursor. A network of `0.0.0.0/0` or `::/0` would allow all IPv4 and IPv6 networks to query this server. This is generally a bad idea.

set service dns forwarding dnssec <off | process-no-validate | process | log-fail | validate>

The PowerDNS recursor has 5 different levels of DNSSEC processing, which can be set with the `dnssec` setting. In order from least to most processing, these are:

- **off** In this mode, no DNSSEC processing takes place. The recursor will not set the DNSSEC OK (DO) bit in the outgoing queries and will ignore the DO and AD bits in queries.
- **process-no-validate** In this mode the recursor acts as a “security aware, non-validating” nameserver, meaning it will set the DO-bit on outgoing queries and will provide DNSSEC related RRsets (NSEC, RRSIG) to clients that ask for them (by means of a DO-bit in the query), except for zones provided through the `auth-zones` setting. It will not do any validation in this mode, not even when requested by the client.
- **process** When `dnssec` is set to process the behavior is similar to process-no-validate. However, the recursor will try to validate the data if at least one of the DO or AD bits is set in the query; in that case, it will set the AD-bit in the response when the data is validated successfully, or send SERVFAIL when the validation comes up bogus.
- **log-fail** In this mode, the recursor will attempt to validate all data it retrieves from authoritative servers, regardless of the client’s DNSSEC desires, and will log the validation result. This mode can be used to determine the extra load and amount of possibly bogus answers before turning on full-blown validation. Responses to client queries are the same as with process.
- **validate** The highest mode of DNSSEC processing. In this mode, all queries will be validated and will be answered with a SERVFAIL in case of bogus data, regardless of the client’s request.

Note: The popular Unix/Linux `dig` tool sets the AD-bit in the query. This might lead to unexpected query results when testing. Set `+noad` on the `dig` command line when this is the case.

Note: The CD-bit is honored correctly for process and validate. For log-fail, failures will be logged too.

set service dns forwarding ignore-hosts-file

Do not use the local `/etc/hosts` file in name resolution. VyOS DHCP server will use this file to add resolvers to assigned addresses.

set service dns forwarding max-cache-entries

Maximum number of DNS cache entries. 1 million per CPU core will generally suffice for most installations.

set service dns forwarding negative-ttl

A query for which there is authoritatively no answer is cached to quickly deny a record's existence later on, without putting a heavy load on the remote server. In practice, caches can become saturated with hundreds of thousands of hosts which are tried only once. This setting, which defaults to 3600 seconds, puts a maximum on the amount of time negative entries are cached.

set service dns forwarding listen-address

The local IPv4 or IPv6 addresses to bind the DNS forwarder to. The forwarder will listen on this address for incoming connections.

set service dns forwarding no-serve-rfc1918

This makes the server authoritatively not aware of: `10.in-addr.arpa`, `168.192.in-addr.arpa`, `16-31.172.in-addr.arpa`, which enabling upstream DNS server(s) to be used for reverse lookups of these zones.

Example

A VyOS router with two interfaces - `eth0` (WAN) and `eth1` (LAN) - is required to implement a split-horizon DNS configuration for `example.com`.

In this scenario:

- All DNS requests for `example.com` must be forwarded to a DNS server at `192.0.2.254` and `2001:db8:cafe::1`
- All other DNS requests will be forwarded to a different set of DNS servers at `192.0.2.1`, `192.0.2.2`, `2001:db8::1:ffff` and `2001:db8::2:ffff`
- The VyOS DNS forwarder will only listen for requests on the `eth1` (LAN) interface addresses - `192.168.1.254` for IPv4 and `2001:db8::ffff` for IPv6
- The VyOS DNS forwarder will only accept lookup requests from the LAN subnets - `192.168.1.0/24` and `2001:db8::/64`
- The VyOS DNS forwarder will pass reverse lookups for `10.in-addr.arpa`, `168.192.in-addr.arpa`, `16-31.172.in-addr.arpa` zones to upstream server.

```
set service dns forwarding domain example.com server 192.0.2.254
set service dns forwarding domain example.com server 2001:db8:cafe::1
set service dns forwarding name-server 192.0.2.1
set service dns forwarding name-server 192.0.2.2
set service dns forwarding name-server 2001:db8::1:ffff
set service dns forwarding name-server 2001:db8::2:ffff
```

(continues on next page)

(continued from previous page)

```
set service dns forwarding listen-address 192.168.1.254
set service dns forwarding listen-address 2001:db8::ffff
set service dns forwarding allow-from 192.168.1.0/24
set service dns forwarding allow-from 2001:db8::/64
set service dns forwarding no-serve-rfc1918
```

Operation

reset dns forwarding <all | domain>

Resets the local DNS forwarding cache database. You can reset the cache for all entries or only for entries to a specific domain.

restart dns forwarding

Restarts the DNS recursor process. This also invalidates the local DNS forwarding cache.

8.10.7 Dynamic DNS

VyOS is able to update a remote DNS record when an interface gets a new IP address. In order to do so, VyOS includes `ddclient`, a Perl script written for this only one purpose.

`ddclient` uses two methods to update a DNS record. The first one will send updates directly to the DNS daemon, in compliance with [RFC 2136](#). The second one involves a third party service, like DynDNS.com or any other similar website. This method uses HTTP requests to transmit the new IP address. You can configure both in VyOS.

Configuration

RFC 2136 Based

```
set service dns dynamic interface <interface> rfc2136 <service-name>
```

Create new [RFC 2136](#) DNS update configuration which will update the IP address assigned to *<interface>* on the service you configured under *<service-name>*.

```
set service dns dynamic interface <interface> rfc2136 <service-name> key  
<keyfile>
```

File identified by *<keyfile>* containing the secret RNDK key shared with remote DNS server.

```
set service dns dynamic interface <interface> rfc2136 <service-name> server  
<server>
```

Configure the DNS *<server>* IP/FQDN used when updating this dynamic assignment.

```
set service dns dynamic interface <interface> rfc2136 <service-name> zone  
<zone>
```

Configure DNS *<zone>* to be updated.

```
set service dns dynamic interface <interface> rfc2136 <service-name> record  
<record>
```

Configure DNS *<record>* which should be updated. This can be set multiple times.

```
set service dns dynamic interface <interface> rfc2136 <service-name> ttl <ttl>
```

Configure optional TTL value on the given resource record. This defaults to 600 seconds.

Example

- Register DNS record `example.vyos.io` on DNS server `ns1.vyos.io`
- Use auth key file at `/config/auth/my.key`
- Set TTL to 300 seconds

```
vyos@vyos# show service dns dynamic
interface eth0.7 {
    rfc2136 VyOS-DNS {
        key /config/auth/my.key
        record example.vyos.io
        server ns1.vyos.io
        ttl 300
        zone vyos.io
    }
}
```

This will render the following `ddclient` configuration entry:

```
#
# ddclient configuration for interface "eth0.7":
#
use=if, if=eth0.7

# RFC2136 dynamic DNS configuration for example.vyos.io.vyos.io
server=ns1.vyos.io
protocol=nsupdate
password=/config/auth/my.key
ttl=300
zone=vyos.io
example.vyos.io
```

Note: You can also keep different DNS zone updated. Just create a new config node: `set service dns dynamic interface <interface> rfc2136 <other-service-name>`

HTTP based services

VyOS is also able to use any service relying on protocols supported by `ddclient`.

To use such a service, one must define a login, password, one or multiple hostnames, protocol and server.

set service dns dynamic interface <interface> service <service> host-name <hostname>

Setup the dynamic DNS hostname *<hostname>* associated with the DynDNS provider identified by *<service>* when the IP address on interface *<interface>* changes.

set service dns dynamic interface <interface> service <service> login <username>

Configure *<username>* used when authenticating the update request for DynDNS service identified by *<service>*. For Namecheap, set the *<domain>* you wish to update.

```
set service dns dynamic interface <interface> service <service> password
<password>
```

Configure *<password>* used when authenticating the update request for DynDNS service identified by *<service>*.

```
set service dns dynamic interface <interface> service <service> protocol
<protocol>
```

When a custom DynDNS provider is used the protocol used for communicating to the provider must be specified under *<protocol>*. See the embedded completion helper for available protocols.

```
set service dns dynamic interface <interface> service <service> server
<server>
```

When a custom DynDNS provider is used the *<server>* where update requests are being sent to must be specified.

Example:

Use DynDNS as your preferred provider:

```
set service dns dynamic interface eth0 service dyndns
set service dns dynamic interface eth0 service dyndns login my-login
set service dns dynamic interface eth0 service dyndns password my-password
set service dns dynamic interface eth0 service dyndns host-name my-dyndns-hostname
```

Note: Multiple services can be used per interface. Just specify as many services per interface as you like!

Running Behind NAT

By default, *ddclient* will update a dynamic dns record using the IP address directly attached to the interface. If your VyOS instance is behind NAT, your record will be updated to point to your internal IP.

ddclient has another way to determine the WAN IP address. This is controlled by:

```
set service dns dynamic interface <interface> use-web url <url>
```

Use configured *<url>* to determine your IP address. *ddclient* will load *<url>* and tries to extract your IP address from the response.

```
set service dns dynamic interface <interface> use-web skip <pattern>
```

ddclient will skip any address located before the string set in *<pattern>*.

8.10.8 HTTP-API

VyOS provide a HTTP API. You can use it to execute op-mode commands, update VyOS, set or delete config.

Please take a look at the [VyOS API](#) page for an detailed how-to.

Configuration

set service https api keys id <name> key <apikey>

Set an named api key, every key have the same, full permissions on the system.

set service https api debug

To enable debug messages. Available via `show log` or `monitor log`

set service https api port

Set the listen port of the local API, this have non effect of the webserver. The default is port 8080

set service https api strict

Enforce strict path checking

set service https virtual-host <vhost> listen-address

Address to listen for HTTPS requests

set service https virtual-host <vhost> listen-port <1-65535>

Port to listen for HTTPS requests; default 443

set service https virtual-host <vhost> server-name <text>

Server names for virtual hosts it ca be exact, wildcard or regex.

set service https api-restrict virtual-host <vhost>

Nginx exposes the local API on all virtual servers, by default Use this to restrict nginx to one or more virtual hosts.

set service https certificates certbot domain-name <text>

Domain name(s) for which to obtain certificate

set service https certificates certbot email

Email address to associate with certificate

set service https certificates system-generated-certificate

Use an automatically generated self-signed certificate

set service https certificates system-generated-certificate lifetime <days>

Lifetime in days; default is 365

Example Configuration

Set an API-KEY is the minimal configuration to get a working API Endpoint.

```
set service https api keys id MY-HTTPS-API-ID key MY-HTTPS-API-PLAINTEXT-KEY
```

To use this full configuration we asume a public accessible hostname.

```
set service https api keys id MY-HTTPS-API-ID key MY-HTTPS-API-PLAINTEXT-KEY
set service https certificates certbot domain-name rtr01.example.com
set service https certificates certbot email mail@example.com
set service https virtual-host rtr01 listen-address 198.51.100.2
set service https virtual-host rtr01 listen-port 11443
```

(continues on next page)

(continued from previous page)

```
set service https virtual-host rtr01 server-name rtr01.example.com
set service https api-restrict virtual-host rtr01.example.com
```

8.10.9 IPoE Server

VyOS utilizes `accel-ppp` to provide IPoE (Internet Protocol over Ethernet) server functionality. It can be used with local authentication (mac-address) or a connected RADIUS server.

IPoE is a method of delivering an IP payload over an Ethernet-based access network or an access network using bridged Ethernet over Asynchronous Transfer Mode (ATM) without using PPPoE. It directly encapsulates the IP datagrams in Ethernet frames, using the standard **RFC 894** encapsulation.

The use of IPoE addresses the disadvantage that PPP is unsuited for multicast delivery to multiple users. Typically, IPoE uses Dynamic Host Configuration Protocol and Extensible Authentication Protocol to provide the same functionality as PPPoE, but in a less robust manner.

Note: Please be aware, due to an upstream bug, config changes/commits will restart the ppp daemon and will reset existing IPoE sessions, in order to become effective.

Configuration

IPoE can be configured on different interfaces, it will depend on each specific situation which interface will provide IPoE to clients. The client's mac address and the incoming interface is being used as a control parameter, to authenticate a client.

The example configuration below will assign an IP to the client on the incoming interface `eth2` with the client mac address `08:00:27:2f:d8:06`. Other DHCP discovery requests will be ignored, unless the client mac has been enabled in the configuration.

```
set service ipoe-server authentication interface eth2 mac-address 08:00:27:2f:d8:06
set service ipoe-server authentication mode 'local'
set service ipoe-server name-server '10.10.1.1'
set service ipoe-server name-server '10.10.1.2'
set service ipoe-server interface eth2 client-subnet '192.168.0.0/24'
```

The first address of the parameter `client-subnet`, will be used as the default gateway. Connected sessions can be checked via the `show ipoe-server sessions` command.

```
vyos@vyos:~$ show ipoe-server sessions
```

ifname	called-sid	calling-sid	ip	ip6	ip6-dp	rate-limit
↪state	uptime	sid				
ipoe0	eth2	08:00:27:2f:d8:06	192.168.0.2			
↪active	00:45:05	dccc870fd3134612				

IPv6 SLAAC and IA-PD

To configure IPv6 assignments for clients, two options need to be configured. A global prefix which is terminated on the client's cpe and a delegated prefix, the client can use for devices routed via the client's cpe.

IPv6 DNS addresses are optional.

```
set service ipoe-server authentication interface eth3 mac-address 08:00:27:2F:D8:06
set service ipoe-server authentication mode 'local'
set service ipoe-server client-ipv6-pool delegate '2001:db8:1::/48' delegation-prefix
↪ '56'
set service ipoe-server client-ipv6-pool prefix '2001:db8::/48' mask '64'
set service ipoe-server name-server '2001:db8::'
set service ipoe-server name-server '2001:db8:aaa::'
set service ipoe-server name-server '2001:db8:bbb::'
set service ipoe-server interface eth3 client-subnet '192.168.1.0/24'
```

```
vyos@ipoe-server# run sh ipoe-server sessions
ifname | called-sid |      calling-sid      | ip      |          ip6          |
↪ | ip6-dp          | rate-limit | state | uptime |          sid          |
-----+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪ --+-----+-----+-----+-----+-----+-----+-----+-----+-----+
ipoe0 | eth3          | 08:00:27:2f:d8:06 | 192.168.1.2 | 2001:db8::a00:27ff:fe2f:d806/
↪ 64 | 2001:db8:1::/56 |          | active | 01:02:59 | 4626faf71b12cc25
```

The clients CPE (Customer Premises Equipment) can now communicate via IPv4 or IPv6. All devices behind 2001:db8::a00:27ff:fe2f:d806/64 can use addresses from 2001:db8:1::/56 and can globally communicate without the need of any NAT rules.

Automatic VLAN creation

To create VLANs per user during runtime, the following settings are required on a per interface basis. VLAN ID and VLAN range can be present in the configuration at the same time.

```
set service ipoe-server interface eth2 network vlan
set service ipoe-server interface eth2 vlan-id 100
set service ipoe-server interface eth2 vlan-id 200
set service ipoe-server interface eth2 vlan-range 1000-2000
set service ipoe-server interface eth2 vlan-range 2500-2700
```

RADIUS Setup

To use a RADIUS server for authentication and bandwidth-shaping, the following example configuration can be used.

```
set service ipoe-server authentication mode 'radius'
set service ipoe-server authentication radius server 10.100.100.1 key 'password'
```

Bandwidth Shaping

Bandwidth rate limits can be set for local users within the configuration or via RADIUS based attributes.

Bandwidth Shaping for local users

The rate-limit is set in kbit/sec.

```

set service ipoe-server authentication interface eth2 mac-address 08:00:27:2f:d8:06
↪rate-limit download '500'
set service ipoe-server authentication interface eth2 mac-address 08:00:27:2f:d8:06
↪rate-limit upload '500'
set service ipoe-server authentication mode 'local'
set service ipoe-server name-server '10.10.1.1'
set service ipoe-server name-server '10.10.1.2'
set service ipoe-server interface eth2 client-subnet '192.168.0.0/24'

```

```
vyos@vyos# run show ipoe-server sessions
```

ifname	called-sid	calling-sid	ip	ip6	ip6-dp	rate-limit
↪state	uptime	sid				
ipoe0	eth2	08:00:27:2f:d8:06	192.168.0.2			500/500
↪active	00:00:05	dccc870fd31349fb				

8.10.10 LLDP

LLDP (Link Layer Discovery Protocol) is a vendor-neutral link layer protocol in the Internet Protocol Suite used by network devices for advertising their identity, capabilities, and neighbors on an IEEE 802 local area network, principally wired Ethernet. The protocol is formally referred to by the IEEE as Station and Media Access Control Connectivity Discovery specified in IEEE 802.1AB and IEEE 802.3-2012 section 6 clause 79.

LLDP performs functions similar to several proprietary protocols, such as CDP (Cisco Discovery Protocol), FDP (Foundry Discovery Protocol), NDP (Nortel Discovery Protocol) and LLTD (Link Layer Topology Discovery).

Information gathered with LLDP is stored in the device as a MIB (Management Information Database) and can be queried with SNMP (Simple Network Management Protocol) as specified in [RFC 2922](#). The topology of an LLDP-enabled network can be discovered by crawling the hosts and querying this database. Information that may be retrieved include:

- System Name and Description
- Port name and description
- VLAN name
- IP management address
- System capabilities (switching, routing, etc.)
- MAC/PHY information
- MDI power
- Link aggregation

Configuration

```
set service lldp
```

Enable LLDP service

```
set service lldp management-address <address>
```

Define IPv4/IPv6 management address transmitted via LLDP. Multiple addresses can be defined. Only addresses connected to the system will be transmitted.

set service lldp interface <interface>

Enable transmission of LLDP information on given <interface>. You can also say `all` here so LLDP is turned on on every interface.

set service lldp interface <interface> disable

Disable transmit of LLDP frames on given <interface>. Useful to exclude certain interfaces from LLDP when all have been enabled.

set service lldp snmp enable

Enable SNMP queries of the LLDP database

set service lldp legacy-protocols <cdp|edp|fdp|sonmp>

Enable given legacy protocol on this LLDP instance. Legacy protocols include:

- `cdp` - Listen for CDP for Cisco routers/switches
- `edp` - Listen for EDP for Extreme routers/switches
- `fdp` - Listen for FDP for Foundry routers/switches
- `sonmp` - Listen for SONMP for Nortel routers/switches

Operation**show lldp neighbors**

Displays information about all neighbors discovered via LLDP.

```
vyos@vyos:~$ show lldp neighbors
Capability Codes: R - Router, B - Bridge, W - Wlan r - Repeater, S - Station
                  D - Docsis, T - Telephone, O - Other

show lldp neighbors interface <interface>

Show LLDP neighbors connected via interface <interface>.

show log lldp

Used for troubleshooting.

8.10.11 mDNS Repeater

Starting with VyOS 1.2 a mDNS (Multicast DNS) repeater functionality is provided. Additional information can be obtained from https://en.wikipedia.org/wiki/Multicast_DNS.

Multicast DNS uses the 224.0.0.251 address, which is “administratively scoped” and does not leave the subnet. It retransmits mDNS packets from one interface to other interfaces. This enables support for e.g. Apple Airplay devices across multiple VLANs.

Since the mDNS protocol sends the AA records in the packet itself, the repeater does not need to forge the source address. Instead, the source address is of the interface that repeats the packet.

Configuration**set service mdns repeater interface <interface>**

To enable mDNS repeater you need to configure at least two interfaces. To re-broadcast all incoming mDNS packets from any interface configured here to any other interface configured under this section.

set service mdns repeater disable

mDNS repeater can be temporarily disabled without deleting the service using

Note: You can not run this in a VRRP setup, if multiple mDNS repeaters are launched in a subnet you will experience the mDNS packet storm death!

Example

To listen on both *eth0* and *eth1* mDNS packets and also repeat packets received on *eth0* to *eth1* (and vice-versa) use the following commands:

```
set service mdns repeater interface 'eth0'
set service mdns repeater interface 'eth1'
```

8.10.12 PPPoE Server

VyOS utilizes `accel-ppp` to provide PPPoE server functionality. It can be used with local authentication or a connected RADIUS server.

Note: Please be aware, due to an upstream bug, config changes/commits will restart the ppp daemon and will reset existing PPPoE connections from connected users, in order to become effective.

Configuration

First steps

set service pppoe-server access-concentrator <name>

Use this command to set a name for this PPPoE-server access concentrator.

set service pppoe-server authentication mode <local | radius>

Use this command to define whether your PPPoE clients will locally authenticate in your VyOS system or in RADIUS server.

set service pppoe-server authentication local-users username <name> password <password>

Use this command to configure the username and the password of a locally configured user.

set service pppoe-server interface <interface>

Use this command to define the interface the PPPoE server will use to listen for PPPoE clients.

set service pppoe-server gateway-address <address>

Use this command to configure the local gateway IP address.

set service pppoe-server name-server <address>

Use this command to set the IPv4 or IPv6 address of every Domain Name Server you want to configure. They will be propagated to PPPoE clients.

Client Address Pools

To automatically assign the client an IP address as tunnel endpoint, a client IP pool is needed. The source can be either RADIUS or a local subnet or IP range definition.

Once the local tunnel endpoint `set service pppoe-server gateway-address '10.1.1.2'` has been defined, the client IP pool can be either defined as a range or as subnet using CIDR notation. If the CIDR notation is used, multiple subnets can be setup which are used sequentially.

Client IP address via IP range definition

set service pppoe-server client-ip-pool start <address>

Use this command to define the first IP address of a pool of addresses to be given to PPPoE clients. It must be within a /24 subnet.

set service pppoe-server client-ip-pool stop <address>

Use this command to define the last IP address of a pool of addresses to be given to PPPoE clients. It must be within a /24 subnet.

```
set service pppoe-server client-ip-pool start '10.1.1.100'
set service pppoe-server client-ip-pool stop '10.1.1.111'
```

Client IP subnets via CIDR notation

set service pppoe-server client-ip-pool subnet <address>

Use this command for every pool of client IP addresses you want to define. The addresses of this pool will be given to PPPoE clients. You must use CIDR notation and it must be within a /24 subnet.

```
set service pppoe-server client-ip-pool subnet '10.1.1.0/24'
set service pppoe-server client-ip-pool subnet '10.1.2.0/24'
set service pppoe-server client-ip-pool subnet '10.1.3.0/24'
```

RADIUS based IP pools (Framed-IP-Address)

To use a radius server, you need to switch to authentication mode RADIUS and then configure it.

set service pppoe-server authentication radius server <address> key <secret>

Use this command to configure the IP address and the shared secret key of your RADIUS server. You can have multiple RADIUS servers configured if you wish to achieve redundancy.

```
set service pppoe-server access-concentrator 'ACN'
set service pppoe-server authentication mode 'radius'
set service pppoe-server authentication radius server 10.1.100.1 key 'secret'
set service pppoe-server interface 'eth1'
set service pppoe-server gateway-address '10.1.1.2'
```

RADIUS provides the IP addresses in the example above via Framed-IP-Address.

RADIUS sessions management DM/CoA

set service pppoe-server authentication radius dynamic-author <key | port | server>

Use this command to configure Dynamic Authorization Extensions to RADIUS so that you can remotely disconnect sessions and change some authentication parameters.

```
set service pppoe-server authentication radius dynamic-author key 'secret123'
set service pppoe-server authentication radius dynamic-author port '3799'
set service pppoe-server authentication radius dynamic-author server '10.1.1.2'
```

Example, from radius-server send command for disconnect client with username test

```
root@radius-server:~# echo "User-Name=test" | radclient -x 10.1.1.2:3799
disconnect secret123
```

You can also use another attributes for identify client for disconnect, like Framed-IP-Address, Acct-Session-Id, etc. Result commands appears in log.

```
show log | match Disconnect*
```

Example for changing rate-limit via RADIUS CoA.

```
echo "User-Name=test,Filter-Id=5000/4000" | radclient 10.1.1.2:3799 coa
secret123
```

Filter-Id=5000/4000 (means 5000Kbit down-stream rate and 4000Kbit up-stream rate) If attribute Filter-Id redefined, replace it in RADIUS CoA request.

Automatic VLAN Creation

set service pppoe-server interface <interface> <vlan-id | vlan range> <text>

VLAN's can be created by accel-ppp on the fly via the use of a Kernel module named *vlan_mon*, which is monitoring incoming vlans and creates the necessary VLAN if required and allowed. VyOS supports the use of either VLAN ID's or entire ranges, both values can be defined at the same time for an interface. When configured, the PPPoE will create the necessary VLANs when required. Once the user session has been cancelled and the VLAN is not needed anymore, VyOS will remove it again.

```
set service pppoe-server interface eth3 vlan-id 100
set service pppoe-server interface eth3 vlan-id 200
set service pppoe-server interface eth3 vlan-range 500-1000
set service pppoe-server interface eth3 vlan-range 2000-3000
```

Bandwidth Shaping

Bandwidth rate limits can be set for local users or RADIUS based attributes.

For Local Users

set service pppoe-server authentication local-users username <name> rate-limit <download | upload>

Use this command to configure a data-rate limit to PPPOoE clients for traffic download or upload. The rate-limit is set in kbit/sec.

```
set service pppoe-server access-concentrator 'ACN'
set service pppoe-server authentication local-users username foo password 'bar'
set service pppoe-server authentication local-users username foo rate-limit download
↪ '20480'
```

(continues on next page)

(continued from previous page)

```

set service pppoe-server authentication local-users username foo rate-limit upload
↪ '10240'
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool start '10.1.1.100'
set service pppoe-server client-ip-pool stop '10.1.1.111'
set service pppoe-server name-server '10.100.100.1'
set service pppoe-server name-server '10.100.200.1'
set service pppoe-server interface 'eth1'
set service pppoe-server gateway-address '10.1.1.2'

```

Once the user is connected, the user session is using the set limits and can be displayed via ‘show pppoe-server sessions’.

```

show pppoe-server sessions
ifname | username | ip | calling-sid | rate-limit | state | uptime ↪
↪ | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----
↪ +-----+-----+
ppp0 | foo | 10.1.1.100 | 00:53:00:ba:db:15 | 20480/10240 | active | 00:00:11 ↪
↪ | 214 B | 76 B

```

For RADIUS users

The current attribute ‘Filter-Id’ is being used as default and can be setup within RADIUS:

Filter-Id=2000/3000 (means 2000Kbit down-stream rate and 3000Kbit up-stream rate)

The command below enables it, assuming the RADIUS connection has been setup and is working.

set service pppoe-server authentication radius rate-limit enable

Use this command to enable bandwidth shaping via RADIUS.

Other attributes can be used, but they have to be in one of the dictionaries in */usr/share/accel-ppp/radius*.

Load Balancing

**set service pppoe-server pado-delay <number-of-ms> sessions
<number-of-sessions>**

Use this command to enable the delay of PADO (PPPoE Active Discovery Offer) packets, which can be used as a session balancing mechanism with other PPPoE servers.

```

set service pppoe-server pado-delay 50 sessions '500'
set service pppoe-server pado-delay 100 sessions '1000'
set service pppoe-server pado-delay 300 sessions '3000'

```

In the example above, the first 499 sessions connect without delay. PADO packets will be delayed 50 ms for connection from 500 to 999, this trick allows other PPPoE servers send PADO faster and clients will connect to other servers. Last command says that this PPPoE server can serve only 3000 clients.

IPv6

IPv6 client's prefix assignment

```
set service pppoe-server client-ipv6-pool prefix <address> mask
<number-of-bits>
```

Use this command to set the IPv6 address pool from which a PPPoE client will get an IPv6 prefix of your defined length (mask) to terminate the PPPoE endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

IPv6 Prefix Delegation

```
set service pppoe-server client-ipv6-pool delegate <address> delegation-prefix
<number-of-bits>
```

Use this command to configure DHCPv6 Prefix Delegation (RFC3633). You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

Maintenance mode

```
set pppoe-server maintenance-mode <enable | disable>
```

For network maintenance, it's a good idea to direct users to a backup server so that the primary server can be safely taken out of service. It's possible to switch your PPPoE server to maintenance mode where it maintains already established connections, but refuses new connection attempts.

Checking connections

```
show pppoe-server sessions
```

Use this command to locally check the active sessions in the PPPoE server.

```
show pppoe-server sessions
ifname | username |      ip      | calling-sid | rate-limit | state | uptime
↪ | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----
↪ +-----+-----+
ppp0   | foo       | 10.1.1.100 | 00:53:00:ba:db:15 | 20480/10240 | active | 00:00:11
↪ | 214 B    | 76 B
```

Per default the user session is being replaced if a second authentication request succeeds. Such session requests can be either denied or allowed entirely, which would allow multiple sessions for a user in the latter case. If it is denied, the second session is being rejected even if the authentication succeeds, the user has to terminate its first session and can then authentication again.

```
vyos@# set service pppoe-server session-control
Possible completions:
disable      Disables session control
deny         Deny second session authorization
```

Examples

IPv4

The example below uses ACN as access-concentrator name, assigns an address from the pool 10.1.1.100-111, terminates at the local endpoint 10.1.1.1 and serves requests only on eth1.

```
set service pppoe-server access-concentrator 'ACN'
set service pppoe-server authentication local-users username foo password 'bar'
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool start '10.1.1.100'
set service pppoe-server client-ip-pool stop '10.1.1.111'
set service pppoe-server interface eth1
set service pppoe-server gateway-address '10.1.1.2'
set service pppoe-server name-server '10.100.100.1'
set service pppoe-server name-server '10.100.200.1'
```

Dual-Stack IPv4/IPv6 provisioning with Prefix Delegation

The example below covers a dual-stack configuration via pppoe-server.

```
set service pppoe-server authentication local-users username test password 'test'
set service pppoe-server authentication mode 'local'
set service pppoe-server client-ip-pool start '192.168.0.1'
set service pppoe-server client-ip-pool stop '192.168.0.10'
set service pppoe-server client-ipv6-pool delegate '2001:db8:8003::/48' delegation-
↳ prefix '56'
set service pppoe-server client-ipv6-pool prefix '2001:db8:8002::/48' mask '64'
set service pppoe-server ppp-options ipv6 allow
set service pppoe-server name-server '10.1.1.1'
set service pppoe-server name-server '2001:db8:4860::8888'
set service pppoe-server interface 'eth2'
set service pppoe-server gateway-address '10.100.100.1'
```

The client, once successfully authenticated, will receive an IPv4 and an IPv6 /64 address to terminate the pppoe endpoint on the client side and a /56 subnet for the clients internal use.

```
vyos@pppoe-server:~$ sh pppoe-server sessions
  ifname | username |      ip      |      ip6      |      ip6-dp      |
↳ calling-sid | rate-limit | state | uptime | rx-bytes | tx-bytes
-----+-----+-----+-----+-----+-----+-----
↳ -----+-----+-----+-----+-----+-----+-----
  ppp0   | test      | 192.168.0.1 | 2001:db8:8002:0:200::/64 | 2001:db8:8003::1/56 |
↳ 00:53:00:12:42:eb |          | active | 00:00:49 | 875 B   | 2.1 KiB
```

8.10.13 Router Advertisements

RAS (Router advertisements) are described in [RFC 4861#section-4.6.2](#). They are part of what is known as SLAAC.

Supported interface types:

- bonding
- bridge
- ethernet
- l2tpv3

- openvpn
- pseudo-ethernet
- tunnel
- vxlan
- wireguard
- wireless
- wirelessmodem

Enabling Advertisements

```
set service router-advert interface <interface> ....
```

Field	VyOS Option	Description
Cur Hop Limit	hop-limit	Hop count field of the outgoing RA packets
“Managed address configuration” flag	managed-flag	Tell hosts to use the administered stateful protocol (i.e. DHCP) for autoconfiguration
“Other configuration” flag	other-config-flag	Tell hosts to use the administered (stateful) protocol (i.e. DHCP) for autoconfiguration of other (non-address) information
MTU	link-mtu	Link MTU value placed in RAs, excluded in RAs if unset
Router Lifetime	default-lifetime	Lifetime associated with the default router in units of seconds
Reachable Time	reachable-time	Time, in milliseconds, that a node assumes a neighbor is reachable after having received a reachability confirmation
Retransmit Timer	retrans-timer	Time in milliseconds between retransmitted Neighbor Solicitation messages
Default Router Preference	default-preference	Preference associated with the default router
Interval	interval	Min and max intervals between unsolicited multicast RAs
DNSSL	dnssl	DNS search list to advertise
Name Server	name-server	Advertise DNS server per https://tools.ietf.org/html/rfc6106

Advertising a Prefix

```
set service router-advert interface <interface> prefix 2001:DB8::/32
```

VyOS Field	Description
no-autonomous-flag	Prefix can not be used for stateless address auto-configuration
no-on-link-flag	Prefix can not be used for on-link determination
preferred-lifetime	Time in seconds that the prefix will remain preferred (default 4 hours)
valid-lifetime	Time in seconds that the prefix will remain valid (default: 30 days)

Disabling Advertisements

To disable advertisements without deleting the configuration:

```
set service router-advert interface <interface> no-send-advert
```

Example Configuration

```
interface eth0.2 {
    default-preference high
    hop-limit 64
    interval {
        max 600
    }
    name-server 2001:db8::1
    name-server 2001:db8::2
    other-config-flag
    prefix 2001:db8:beef:2::/64 {
        valid-lifetime 2592000
    }
    reachable-time 0
    retrans-timer 0
}
```

8.10.14 Salt-Minion

SaltStack is Python-based, open-source software for event-driven IT automation, remote task execution, and configuration management. Supporting the “infrastructure as code” approach to data center system and network deployment and management, configuration automation, SecOps orchestration, vulnerability remediation, and hybrid cloud control.

Requirements

To use the Salt-Minion, a running Salt-Master is required. You can find more in the [Salt Project Documentaion](#)

Configuration

```
set service salt-minion hash <type>
```

The hash type used when discovering file on master server (default: sha256)

```
set service salt-minion id <id>
```

Explicitly declare ID for this minion to use (default: hostname)

```
set service salt-minion interval <1-1440>
```

Interval in minutes between updates (default: 60)

```
set service salt-minion master <hostname | IP>
```

The hostname or IP address of the master

```
set service salt-minion master-key <key>
```

URL with signature of master for auth reply verification

Please take a look in the Automation section to find some usefull Examples.

8.10.15 SNMP

SNMP is an Internet Standard protocol for collecting and organizing information about managed devices on IP networks and for modifying that information to change device behavior. Devices that typically support SNMP include cable modems, routers, switches, servers, workstations, printers, and more.

SNMP is widely used in network management for network monitoring. SNMP exposes management data in the form of variables on the managed systems organized in a management information base (MIB) which describe the system status and configuration. These variables can then be remotely queried (and, in some circumstances, manipulated) by managing applications.

Three significant versions of SNMP have been developed and deployed. SNMPv1 is the original version of the protocol. More recent versions, SNMPv2c and SNMPv3, feature improvements in performance, flexibility and security.

SNMP is a component of the Internet Protocol Suite as defined by the Internet Engineering Task Force (IETF). It consists of a set of standards for network management, including an application layer protocol, a database schema, and a set of data objects.

Overview and basic concepts

In typical uses of SNMP, one or more administrative computers called managers have the task of monitoring or managing a group of hosts or devices on a computer network. Each managed system executes a software component called an agent which reports information via SNMP to the manager.

An SNMP-managed network consists of three key components:

- Managed devices
- Agent - software which runs on managed devices
- Network management station (NMS) - software which runs on the manager

A managed device is a network node that implements an SNMP interface that allows unidirectional (read-only) or bidirectional (read and write) access to node-specific information. Managed devices exchange node-specific information with the NMSs. Sometimes called network elements, the managed devices can be any type of device, including, but not limited to, routers, access servers, switches, cable modems, bridges, hubs, IP telephones, IP video cameras, computer hosts, and printers.

An agent is a network-management software module that resides on a managed device. An agent has local knowledge of management information and translates that information to or from an SNMP-specific form.

A network management station executes applications that monitor and control managed devices. NMSs provide the bulk of the processing and memory resources required for network management. One or more NMSs may exist on any managed network.

Note: VyOS SNMP supports both IPv4 and IPv6.

SNMP Protocol Versions

VyOS itself supports [SNMPv2](#) (version 2) and [SNMPv3](#) (version 3) where the later is recommended because of improved security (optional authentication and encryption).

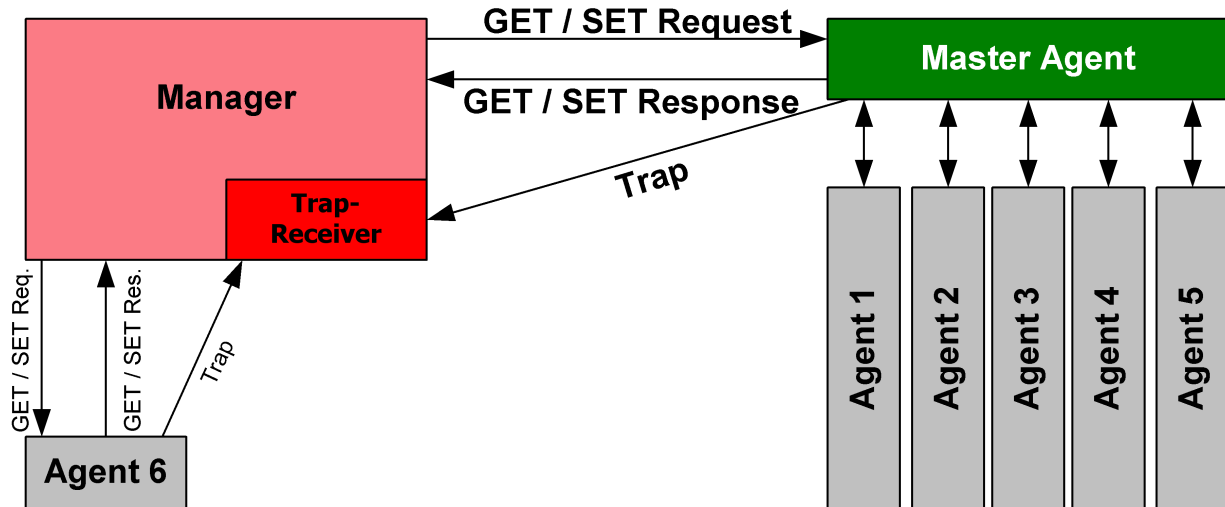

Fig. 5: Image thankfully borrowed from https://en.wikipedia.org/wiki/File:SNMP_communication_principles_diagram.PNG which is under the GNU Free Documentation License

SNMPv2

SNMPv2 is the original and most commonly used version. For authorizing clients, SNMP uses the concept of communities. Communities may have authorization set to read only (this is most common) or to read and write (this option is not actively used in VyOS).

SNMP can work synchronously or asynchronously. In synchronous communication, the monitoring system queries the router periodically. In asynchronous, the router sends notification to the “trap” (the monitoring host).

SNMPv2 does not support any authentication mechanisms, other than client source address, so you should specify addresses of clients allowed to monitor the router. Note that SNMPv2 also supports no encryption and always sends data in plain text.

Example

```
# Define a community
set service snmp community routers authorization ro

# Allow monitoring access from the entire network
set service snmp community routers network 192.0.2.0/24
set service snmp community routers network 2001::db8:ffff:eeee::/64

# Allow monitoring access from specific addresses
set service snmp community routers client 203.0.113.10
set service snmp community routers client 203.0.113.20

# Define optional router information
set service snmp location "UK, London"
set service snmp contact "admin@example.com"

# Trap target if you want asynchronous communication
```

(continues on next page)

(continued from previous page)

```
set service snmp trap-target 203.0.113.10

# Listen only on specific IP addresses (port defaults to 161)
set service snmp listen-address 172.16.254.36 port 161
set service snmp listen-address 2001:db8::f00::1
```

SNMPv3

SNMPv3 (version 3 of the SNMP protocol) introduced a whole slew of new security related features that have been missing from the previous versions. Security was one of the biggest weakness of SNMP until v3. Authentication in SNMP Versions 1 and 2 amounts to nothing more than a password (community string) sent in clear text between a manager and agent. Each SNMPv3 message contains security parameters which are encoded as an octet string. The meaning of these security parameters depends on the security model being used.

The security approach in v3 targets:

- Confidentiality – Encryption of packets to prevent snooping by an unauthorized source.
- Integrity – Message integrity to ensure that a packet has not been tampered while in transit including an optional packet replay protection mechanism.
- Authentication – to verify that the message is from a valid source.

Example

- Let SNMP daemon listen only on IP address 192.0.2.1
- Configure new SNMP user named “vyos” with password “vyos12345678”
- New user will use SHA/AES for authentication and privacy

```
set service snmp listen-address 192.0.2.1
set service snmp location 'VyOS Datacenter'
set service snmp v3 engineid '000000000000000000000002'
set service snmp v3 group default mode 'ro'
set service snmp v3 group default view 'default'
set service snmp v3 user vyos auth plaintext-password 'vyos12345678'
set service snmp v3 user vyos auth type 'sha'
set service snmp v3 user vyos group 'default'
set service snmp v3 user vyos privacy plaintext-password 'vyos12345678'
set service snmp v3 user vyos privacy type 'aes'
set service snmp v3 view default oid 1
```

After commit the plaintext passwords will be hashed and stored in your configuration. The resulting LCI config will look like:

```
vyos@vyos# show service snmp
listen-address 172.18.254.201 {
}
location "Wuerzburg, Dr.-Georg-Fuchs-Str. 8"
v3 {
  engineid 000000000000000000000002
  group default {
    mode ro
    view default
```

(continues on next page)

(continued from previous page)

```

    }
    user vyos {
        auth {
            encrypted-password 4e52fe55fd011c9c51ae2c65f4b78ca93dcafdfe
            type sha
        }
        group default
        privacy {
            encrypted-password 4e52fe55fd011c9c51ae2c65f4b78ca93dcafdfe
            type aes
        }
    }
    view default {
        oid 1 {
        }
    }
}

```

You can test the SNMPv3 functionality from any linux based system, just run the following command: `snmpwalk -v 3 -u vyos -a SHA -A vyos12345678 -x AES -X vyos12345678 -l authPriv 192.0.2.1 .1`

VyOS MIBs

All SNMP MIBs are located in each image of VyOS here: `/usr/share/snmp/mibs/`

You are be able to download the files using SCP, once the SSH service has been activated like so

```
scp -r vyos@your_router:/usr/share/snmp/mibs /your_folder/mibs
```

SNMP Extensions

To extend SNMP agent functionality, custom scripts can be executed every time the agent is being called. This can be achieved by using arbitrary extension commands. The first step is to create a functional script of course, then upload it to your VyOS instance via the command `scp your_script.sh vyos@your_router:/config/user-data`. Once the script is uploaded, it needs to be configured via the command below.

```
set service snmp script-extensions extension-name my-extension script your_script.sh
commit
```

The OID `.1.3.6.1.4.1.8072.1.3.2.3.1.1.4.116.101.115.116`, once called, will contain the output of the extension.

```

root@vyos:/home/vyos# snmpwalk -v2c -c public 127.0.0.1 nsExtendOutput1
NET-SNMP-EXTEND-MIB::nsExtendOutput1Line."my-extension" = STRING: hello
NET-SNMP-EXTEND-MIB::nsExtendOutputFull."my-extension" = STRING: hello
NET-SNMP-EXTEND-MIB::nsExtendOutNumLines."my-extension" = INTEGER: 1
NET-SNMP-EXTEND-MIB::nsExtendResult."my-extension" = INTEGER: 0

```

SolarWinds

If you happen to use SolarWinds Orion as NMS you can also use the Device Templates Management. A template for VyOS can be easily imported.

Create a file named `VyOS-1.3.6.1.4.1.44641.ConfigMgmt-Commands` using the following content:

```
<Configuration-Management Device="VyOS" SystemOID="1.3.6.1.4.1.44641">
  <Commands>
    <Command Name="Reset" Value="set terminal width 0${CRLF}set terminal length 0
↵"/>
    <Command Name="Reboot" Value="reboot${CRLF}Yes"/>
    <Command Name="EnterConfigMode" Value="configure"/>
    <Command Name="ExitConfigMode" Value="commit${CRLF}exit"/>
    <Command Name="DownloadConfig" Value="show configuration commands"/>
    <Command Name="SaveConfig" Value="commit${CRLF}save"/>
    <Command Name="Version" Value="show version"/>
    <Command Name="MenuBased" Value="False"/>
    <Command Name="VirtualPrompt" Value=":~"/>
  </Commands>
</Configuration-Management>
```

8.10.16 SSH

SSH (Secure Shell) is a cryptographic network protocol for operating network services securely over an unsecured network. The standard TCP port for SSH is 22. The best known example application is for remote login to computer systems by users.

SSH provides a secure channel over an unsecured network in a client-server architecture, connecting an SSH client application with an SSH server. Common applications include remote command-line login and remote command execution, but any network service can be secured with SSH. The protocol specification distinguishes between two major versions, referred to as SSH-1 and SSH-2.

The most visible application of the protocol is for access to shell accounts on Unix-like operating systems, but it sees some limited use on Windows as well. In 2015, Microsoft announced that they would include native support for SSH in a future release.

SSH was designed as a replacement for Telnet and for unsecured remote shell protocols such as the Berkeley rlogin, rsh, and rexec protocols. Those protocols send information, notably passwords, in plaintext, rendering them susceptible to interception and disclosure using packet analysis. The encryption used by SSH is intended to provide confidentiality and integrity of data over an unsecured network, such as the Internet.

Note: VyOS 1.1 supported login as user `root`. This has been removed due to tighter security in VyOS 1.2.

See also:

SSH *Key Based Authentication*

Configuration

set service ssh port <port>

Enabling SSH only requires you to specify the port <port> you want SSH to listen on. By default, SSH runs on port 22.

set service ssh listen-address <address>

Specify IPv4/IPv6 listen address of SSH server. Multiple addresses can be defined.

set service ssh ciphers <cipher>

Define allowed ciphers used for the SSH connection. A number of allowed ciphers can be specified, use multiple occurrences to allow multiple ciphers.

List of supported ciphers: 3des-cbc, aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr, arcfour128, arcfour256, arcfour, blowfish-cbc, cast128-cbc

set service ssh disable-password-authentication

Disable password based authentication. Login via SSH keys only. This hardens security!

set service ssh disable-host-validation

Disable the host validation through reverse DNS lookups - can speedup login time when reverse lookup is not possible.

set service ssh macs <mac>

Specifies the available MAC algorithms. The MAC algorithm is used in protocol version 2 for data integrity protection. Multiple algorithms can be provided.

List of supported MACs: hmac-md5, hmac-md5-96, hmac-ripemd160, hmac-sha1, hmac-sha1-96, hmac-sha2-256, hmac-sha2-512, umac-64@openssh.com, umac-128@openssh.com, hmac-md5-etm@openssh.com, hmac-md5-96-etm@openssh.com, hmac-ripemd160-etm@openssh.com, hmac-sha1-etm@openssh.com, hmac-sha1-96-etm@openssh.com, hmac-sha2-256-etm@openssh.com, hmac-sha2-512-etm@openssh.com, umac-64-etm@openssh.com, umac-128-etm@openssh.com

set service ssh access-control <allow | deny> <group | user> <name>

Add access-control directive to allow or deny users and groups. Directives are processed in the following order of precedence: deny-users, allow-users, deny-groups and allow-groups.

set service ssh client-keepalive-interval <interval>

Specify timeout interval for keepalive message in seconds.

set service ssh key-exchange <kex>

Specify allowed KEX (Key Exchange) algorithms.

List of supported algorithms: diffie-hellman-group1-sha1, diffie-hellman-group14-sha1, diffie-hellman-group14-sha256, diffie-hellman-group16-sha512, diffie-hellman-group18-sha512, diffie-hellman-group-exchange-sha1, diffie-hellman-group-exchange-sha256, ecdh-sha2-nistp256, ecdh-sha2-nistp384, ecdh-sha2-nistp521, curve25519-sha256 and curve25519-sha256@libssh.org.

set service ssh loglevel <quiet | fatal | error | info | verbose>

Set the sshd log level. The default is info.

set service ssh vrf <name>

Specify name of the VRF (Virtual Routing and Forwarding) instance.

Operation

restart ssh

Restart the SSH daemon process, the current session is not affected, only the background daemon is restarted.

generate ssh server-key

Re-generated the public/private keyportion which SSH uses to secure connections.

Note: Already learned known_hosts files of clients need an update as the public key will change.

generate ssh client-key /path/to/private_key

Re-generated a known pub/private keyfile which can be used to connect to other services (e.g. RPKI cache).

Example:

```
vyos@vyos:~$ generate ssh client-key /config/auth/id_rsa_rpk
Generating public/private rsa key pair.
Your identification has been saved in /config/auth/id_rsa_rpk
Your public key has been saved in /config/auth/id_rsa_rpk.pub
The key fingerprint is:
SHA256:XGv2PpdOzVCzpmEzJZga8hTRq7B/ZYL3fXaioLFLS5Q cpo@LR1.wue3
The key's randomart image is:
+---[RSA 2048]-----+
|          oo         |
|          ..o        |
|       . o.o.. o.    |
|      o+ooo  o.o     |
|      Eo*   =.o      |
|      o = +.o*+      |
|      = o *.o.o      |
|      o * +.o+.+     |
|      =.. o=.oo      |
+-----[SHA256]-----+
```

Two new files /config/auth/id_rsa_rpk and /config/auth/id_rsa_rpk.pub will be created.

generate public-key-commands name <username> path <location>

Generate the configuration mode commands to add a public key for *Key Based Authentication*.
<location> can be a local path or a URL pointing at a remote file.

Supported remote protocols are FTP, HTTP, HTTPS, SCP/SFTP and TFTP.

Example:

```
alyssa@vyos:~$ generate public-key-commands name alyssa path sftp://example.net/
→home/alyssa/.ssh/id_rsa.pub
# To add this key as an embedded key, run the following commands:
configure
set system login user alyssa authentication public-keys alyssa@example.net key_
→AAA...
set system login user alyssa authentication public-keys alyssa@example.net type_
→ssh-rsa
commit
save
exit

ben@vyos:~$ generate public-key-command user ben path ~/.ssh/id_rsa.pub
# To add this key as an embedded key, run the following commands:
configure
set system login user ben authentication public-keys ben@vyos key AAA...
set system login user ben authentication public-keys ben@vyos type ssh-dss
```

(continues on next page)

(continued from previous page)

```
commit
save
exit
```

8.10.17 TFTP Server

TFTP (Trivial File Transfer Protocol) is a simple, lockstep file transfer protocol which allows a client to get a file from or put a file onto a remote host. One of its primary uses is in the early stages of nodes booting from a local area network. TFTP has been used for this application because it is very simple to implement.

Configuration

set service tftp-server directory <directory>

Enable TFTP service by specifying the <directory> which will be used to serve files.

Hint: Choose your `directory` location carefully or you will loose the content on image upgrades. Any directory under `/config` is save at this will be migrated.

set service tftp-server listen-address <address>

Configure the IPv4 or IPv6 listen address of the TFTP server. Multiple IPv4 and IPv6 addresses can be given. There will be one TFTP server instances listening on each IP address.

Note: Configuring a listen-address is essential for the service to work.

set service tftp-server allow-upload

Optional, if you want to enable uploads, else TFTP server will act as a read-only server.

Example

Provide TFTP server listening on both IPv4 and IPv6 addresses `192.0.2.1` and `2001:db8::1` serving the content from `/config/tftpboot`. Uploading via TFTP to this server is disabled.

The resulting configuration will look like:

```
vyos@vyos# show service
tftp-server {
    directory /config/tftpboot
    listen-address 2001:db8::1
    listen-address 192.0.2.1
}
```

Verification

Client:

```
vyos@RTR2:~$ tftp -p -l /config/config.boot -r backup 192.0.2.1
backup1          100% |*****|          723  0:00:00 ETA
```

Server:

```
vyos@RTR1# ls -ltr /config/tftpboot/
total 1
-rw-rw-rw- 1 tftp tftp  1995 May 19 16:02 backup
```

8.10.18 Webproxy

The proxy service in VyOS is based on [Squid](#) and some related modules.

[Squid](#) is a caching and forwarding HTTP web proxy. It has a wide variety of uses, including speeding up a web server by caching repeated requests, caching web, DNS and other computer network lookups for a group of people sharing network resources, and aiding security by filtering traffic. Although primarily used for HTTP and FTP, Squid includes limited support for several other protocols including Internet Gopher, SSL,[6] TLS and HTTPS. Squid does not support the SOCKS protocol.

URL Filtering is provided by [SquidGuard](#).

Configuration

set service webproxy append-domain <domain>

Use this command to specify a domain name to be appended to domain-names within URLs that do not include a dot . the domain is appended.

Example: to be appended is set to `vyos.net` and the URL received is `www/foo.html`, the system will use the generated, final URL of `www.vyos.net/foo.html`.

```
set service webproxy append-domain vyos.net
```

set service webproxy cache-size <size>

The size of the on-disk Proxy cache is user configurable. The Proxies default cache-size is configured to 100 MB.

Unit of this command is MB.

```
set service webproxy cache-size 1024
```

set service webproxy default-port <port>

Specify the port used on which the proxy service is listening for requests. This port is the default port used for the specified listen-address.

Default port is 3128.

```
set service webproxy default-port 8080
```

set service webproxy domain-block <domain>

Used to block specific domains by the Proxy. Specifying “`vyos.net`” will block all access to `vyos.net`, and specifying “`.xxx`” will block all access to URLs having an URL ending on `.xxx`.

```
set service webproxy domain-block vyos.net
```

set service webproxy domain-noncache <domain>

Allow access to sites in a domain without retrieving them from the Proxy cache. Specifying “vyos.net” will allow access to vyos.net but the pages accessed will not be cached. It useful for working around problems with “If-Modified-Since” checking at certain sites.

```
set service webproxy domain-noncache vyos.net
```

set service webproxy listen-address <address>

Specifies proxy service listening address. The listen address is the IP address on which the web proxy service listens for client requests.

For security, the listen address should only be used on internal/trusted networks!

```
set service webproxy listen-address 192.0.2.1
```

set service webproxy listen-address <address> disable-transparent

Disables web proxy transparent mode at a listening address.

In transparent proxy mode, all traffic arriving on port 80 and destined for the Internet is automatically forwarded through the proxy. This allows immediate proxy forwarding without configuring client browsers.

Non-transparent proxying requires that the client browsers be configured with the proxy settings before requests are redirected. The advantage of this is that the client web browser can detect that a proxy is in use and can behave accordingly. In addition, web-transmitted malware can sometimes be blocked by a non-transparent web proxy, since they are not aware of the proxy settings.

```
set service webproxy listen-address 192.0.2.1 disable-transparent
```

set service webproxy listen-address <address> port <port>

Sets the listening port for a listening address. This overrides the default port of 3128 on the specific listen address.

```
set service webproxy listen-address 192.0.2.1 port 8080
```

set service webproxy reply-block-mime <mime>

Used to block a specific mime-type.

```
# block all PDFs
set service webproxy reply-block-mime application/pdf
```

set service webproxy reply-body-max-size <size>

Specifies the maximum size of a reply body in KB, used to limit the reply size.

All reply sizes are accepted by default.

```
set service webproxy reply-body-max-size 2048
```

Authentication

The embedded Squid proxy can use LDAP to authenticate users against a company wide directory. The following configuration is an example of how to use Active Directory as authentication backend. Queries are done via LDAP.

set service webproxy authentication children <number>

Maximum number of authenticator processes to spawn. If you start too few Squid will have to wait for them to process a backlog of credential verifications, slowing it down. When password verifications are done via a (slow) network you are likely to need lots of authenticator processes.

This defaults to 5.

```
set service webproxy authentication children 10
```

set service webproxy authentication credentials-ttl <time>

Specifies how long squid assumes an externally validated username:password pair is valid for - in other words how often the helper program is called for that user. Set this low to force revalidation with short lived passwords.

Time is in minutes and defaults to 60.

```
set service webproxy authentication credentials-ttl 120
```

set service webproxy authentication method <ldap>

Proxy authentication method, currently only LDAP is supported.

```
set service webproxy authentication method ldap
```

set service webproxy authentication realm

Specifies the protection scope (aka realm name) which is to be reported to the client for the authentication scheme. It is commonly part of the text the user will see when prompted for their username and password.

```
set service webproxy authentication realm "VyOS proxy auth"
```

LDAP**set service webproxy authentication ldap base-dn <base-dn>**

Specifies the base DN under which the users are located.

```
set service webproxy authentication ldap base-dn DC=vyos,DC=net
```

set service webproxy authentication ldap bind-dn <bind-dn>

The DN and password to bind as while performing searches.

```
set service webproxy authentication ldap bind-dn CN=proxyuser,CN=Users,DC=vyos,  
→DC=net
```

set service webproxy authentication ldap filter-expression <expr>

LDAP search filter to locate the user DN. Required if the users are in a hierarchy below the base DN, or if the login name is not what builds the user specific part of the users DN.

The search filter can contain up to 15 occurrences of %s which will be replaced by the username, as in “uid=%s” for [RFC 2037](#) directories. For a detailed description of LDAP search filter syntax see [RFC 2254](#).

```
set service webproxy authentication ldap filter-expression (cn=%s)
```

set service webproxy authentication ldap password <password>

The DN and password to bind as while performing searches. As the password needs to be printed in plain text in your Squid configuration it is strongly recommended to use a account with minimal associated privileges. This to limit the damage in case someone could get hold of a copy of your Squid configuration file.

```
set service webproxy authentication ldap password vyos
```

set service webproxy authentication ldap persistent-connection

Use a persistent LDAP connection. Normally the LDAP connection is only open while validating a username to preserve resources at the LDAP server. This option causes the LDAP connection to be kept open, allowing it to be reused for further user validations.

Recommended for larger installations.

```
set service webproxy authentication ldap persistent-connection
```

set service webproxy authentication ldap port <port>

Specify an alternate TCP port where the ldap server is listening if other than the default LDAP port 389.

```
set service webproxy authentication ldap port 389
```

set service webproxy authentication ldap server <server>

Specify the LDAP server to connect to.

```
set service webproxy authentication ldap server ldap.vyos.net
```

set service webproxy authentication ldap use-ssl

Use TLS encryption.

```
set service webproxy authentication ldap use-ssl
```

set service webproxy authentication ldap username-attribute <attr>

Specifies the name of the DN attribute that contains the username/login. Combined with the base DN to construct the users DN when no search filter is specified (*filter-expression*).

Defaults to 'uid'

Note: This can only be done if all your users are located directly under the same position in the LDAP tree and the login name is used for naming each user object. If your LDAP tree does not match these criterias or if you want to filter who are valid users then you need to use a search filter to search for your users DN (*filter-expression*).

```
set service webproxy authentication ldap username-attribute uid
```

set service webproxy authentication ldap version <2 | 3>

LDAP protocol version. Defaults to 3 if not specified.

```
set service webproxy authentication ldap version 2
```

URL filtering

set service webproxy url-filtering disable

Disables web filtering without discarding configuration.

```
set service webproxy url-filtering disable
```

Operation

Filtering

Update

If you want to use existing blacklists you have to create/download a database first. Otherwise you will not be able to commit the config changes.

update webproxy blacklists

Download/Update complete blacklist

```
vyos@vyos:~$ update webproxy blacklists
Warning: No url-filtering blacklist installed
Would you like to download a default blacklist? [confirm][y]
Connecting to ftp.univ-tlse1.fr (193.49.48.249:21)
blacklists.gz          100%
→|*****
→17.0M  0:00:00 ETA

Building DB for [agressif/urls] - 36 entries
Building DB for [arjel/domains] - 69 entries
...

Building DB for [webmail/domains] - 374 entries
Building DB for [webmail/urls] - 9 entries

The webproxy daemon must be restarted
Would you like to restart it now? [confirm][y]

[ ok ] Restarting squid (via systemctl): squid.service.
vyos@vyos:~$
```

update webproxy blacklists category <category>

Download/Update partial blacklist.

Use tab completion to get a list of categories.

- To auto update the blacklist files

```
set service webproxy url-filtering squidguard auto-update update-hour 23
```

- To configure blocking add the following to the configuration

```
set service webproxy url-filtering squidguard block-category ads
```

```
set service webproxy url-filtering squidguard block-category malware
```

Bypassing the webproxy

Some services don't work correctly when being handled via a web proxy. So sometimes it is useful to bypass a transparent proxy:

- To bypass the proxy for every request that is directed to a specific destination:

```
set service webproxy whitelist destination-address 198.51.100.33
set service webproxy whitelist destination-address 192.0.2.0/24
```

- To bypass the proxy for every request that is coming from a specific source:

```
set service webproxy whitelist source-address 192.168.1.2
set service webproxy whitelist source-address 192.168.2.0/24
```

(This can be useful when a called service has many and/or often changing destination addresses - e.g. Netflix.)

Examples

```
vyos@vyos# show service webproxy
authentication {
  children 5
  credentials-ttl 60
  ldap {
    base-dn DC=example,DC=local
    bind-dn CN=proxyuser,CN=Users,DC=example,DC=local
    filter-expression (cn=%s)
    password Qwert1234
    server ldap.example.local
    username-attribute cn
  }
  method ldap
  realm "VyOS Webproxy"
}
cache-size 100
default-port 3128
listen-address 192.168.188.103 {
  disable-transparent
}
```

8.11 System

8.11.1 Serial Console

For the average user a serial console has no advantage over a console offered by a directly attached keyboard and screen. Serial consoles are much slower, taking up to a second to fill a 80 column by 24 line screen. Serial consoles generally only support non-proportional ASCII text, with limited support for languages other than English.

There are some scenarios where serial consoles are useful. System administration of remote computers is usually done using *SSH*, but there are times when access to the console is the only way to diagnose and correct software failures. Major upgrades to the installed distribution may also require console access.

set system console device <device>

Defines the specified device as a system console. Available console devices can be (see completion helper):

- `ttysN` - Serial device name
- `ttysUSBX` - USB Serial device name
- `hvc0` - Xen console

set system console device <device> speed <speed>

The speed (baudrate) of the console device. Supported values are:

- 1200 - 1200 bps
- 2400 - 2400 bps
- 4800 - 4800 bps
- 9600 - 9600 bps
- 19200 - 19,200 bps
- 38400 - 38,400 bps (default for Xen console)
- 57600 - 57,600 bps
- 115200 - 115,200 bps (default for serial console)

Note: If you use USB to serial converters for connecting to your VyOS appliance please note that most of them use software emulation without flow control. This means you should start with a common baud rate (most likely 9600 baud) as otherwise you probably can not connect to the device using high speed baud rates as your serial converter simply can not process this data rate.

8.11.2 Flow Accounting

VyOS supports flow-accounting for both IPv4 and IPv6 traffic. The system acts as a flow exporter, and you are free to use it with any compatible collector.

Flows can be exported via two different protocols: NetFlow (versions 5, 9 and 10/IPFIX) and sFlow. Additionally, you may save flows to an in-memory table internally in a router.

<p>Warning: You need to disable the in-memory table in production environments! Using IMT (In-Memory Table) may lead to heavy CPU overloading and unstable flow-accounting behavior.</p>

NetFlow / IPFIX

NetFlow is a feature that was introduced on Cisco routers around 1996 that provides the ability to collect IP network traffic as it enters or exits an interface. By analyzing the data provided by NetFlow, a network administrator can determine things such as the source and destination of traffic, class of service, and the causes of congestion. A typical flow monitoring setup (using NetFlow) consists of three main components:

- **exporter:** aggregates packets into flows and exports flow records towards one or more flow collectors
- **collector:** responsible for reception, storage and pre-processing of flow data received from a flow exporter
- **application:** analyzes received flow data in the context of intrusion detection or traffic profiling, for example

For connectionless protocols as like ICMP and UDP, a flow is considered complete once no more packets for this flow appear after configurable timeout.

NetFlow is usually enabled on a per-interface basis to limit load on the router components involved in NetFlow, or to limit the amount of NetFlow records exported.

Configuration

In order for flow accounting information to be collected and displayed for an interface, the interface must be configured for flow accounting.

set system flow-accounting interface <interface>

Configure and enable collection of flow information for the interface identified by <interface>.

You can configure multiple interfaces which would participate in flow accounting.

Note: Will be recorded only packets/flows on **incoming** direction in configured interfaces by default.

By default, recorded flows will be saved internally and can be listed with the CLI command. You may disable using the local in-memory table with the command:

set system flow-accounting disable-imt

If you need to sample also egress traffic, you may want to configure egress flow-accounting:

set system flow-accounting enable-egress

Internally, in flow-accounting processes exist a buffer for data exchanging between core process and plugins (each export target is a separated plugin). If you have high traffic levels or noted some problems with missed records or stopping exporting, you may try to increase a default buffer size (10 MiB) with the next command:

set system flow-accounting buffer-size <buffer size>

In case, if you need to catch some logs from flow-accounting daemon, you may configure logging facility:

set system flow-accounting syslog-facility <facility>

TBD

Flow Export

In addition to displaying flow accounting information locally, one can also exported them to a collection server.

NetFlow

set system flow-accounting netflow version <version>

There are multiple versions available for the NetFlow data. The <version> used in the exported flow data can be configured here. The following versions are supported:

- **5** - Most common version, but restricted to IPv4 flows only
- **9** - NetFlow version 9 (default)
- **10** - IPFIX (IP Flow Information Export) as per [RFC 3917](#)

set system flow-accounting netflow server <address>

Configure address of NetFlow collector. NetFlow server at <address> can be both listening on an IPv4 or IPv6 address.

```
set system flow-accounting netflow source-ip <address>
```

IPv4 or IPv6 source address of NetFlow packets

```
set system flow-accounting netflow engine-id <id>
```

NetFlow engine-id which will appear in NetFlow data. The range is 0 to 255.

```
set system flow-accounting netflow sampling-rate <rate>
```

Use this command to configure the sampling rate for flow accounting. The system samples one in every *<rate>* packets, where *<rate>* is the value configured for the sampling-rate option. The advantage of sampling every *n* packets, where *n* > 1, allows you to decrease the amount of processing resources required for flow accounting. The disadvantage of not sampling every packet is that the statistics produced are estimates of actual data flows.

Per default every packet is sampled (that is, the sampling rate is 1).

```
set system flow-accounting netflow timeout expiry-interval <interval>
```

Specifies the interval at which Netflow data will be sent to a collector. As per default, Netflow data will be sent every 60 seconds.

You may also additionally configure timeouts for different types of connections.

```
set system flow-accounting netflow max-flows <n>
```

If you want to change the maximum number of flows, which are tracking simultaneously, you may do this with this command (default 8192).

sFlow

```
set system flow-accounting sflow server <address>
```

Configure address of sFlow collector. sFlow server at *<address>* can be an IPv4 or IPv6 address. But you cannot export to both IPv4 and IPv6 collectors at the same time!

```
set system flow-accounting sflow sampling-rate <rate>
```

Enable sampling of packets, which will be transmitted to sFlow collectors.

```
set system flow-accounting sflow agent-address <address>
```

Configure a sFlow agent address. It can be IPv4 or IPv6 address, but you must set the same protocol, which is used for sFlow collector addresses. By default, using router-id from BGP or OSPF protocol, or the primary IP address from the first interface.

Example:

NetFlow v5 example:

```
set system flow-accounting netflow engine-id 100
set system flow-accounting netflow version 5
set system flow-accounting netflow server 192.168.2.10 port 2055
```

Operation

Once flow accounting is configured on an interfaces it provides the ability to display captured network traffic information for all configured interfaces.

```
show flow-accounting interface <interface>
```

Show flow accounting information for given *<interface>*.

```
vyos@vyos:~$ show flow-accounting interface eth0
```

8.11.3 Host Information

This section describes the system's host information and how to configure them, it covers the following topics:

- Host name
- Domain
- IP address
- Aliases

Hostname

A hostname is the label (name) assigned to a network device (a host) on a network and is used to distinguish one device from another on specific networks or over the internet. On the other hand this will be the name which appears on the command line prompt.

```
set system host-name <hostname>
```

The hostname can be up to 63 characters. A hostname must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.

The default hostname used is *vyos*.

Domain Name

A domain name is the label (name) assigned to a computer network and is thus unique. VyOS appends the domain name as a suffix to any unqualified name. For example, if you set the domain name *example.com*, and you would ping the unqualified name of *crux*, then VyOS qualifies the name to *crux.example.com*.

```
set system domain-name <domain>
```

Configure system domain name. A domain name must start and end with a letter or digit, and have as interior characters only letters, digits, or a hyphen.

Static Hostname Mapping

How an IP address is assigned to an interface in *Ethernet*. This section shows how to statically map an IP address to a hostname for local (meaning on this VyOS instance) name resolution.

```
set system static-host-mapping host-name <hostname> inet <address>
```

Create a static hostname mapping which will always resolve the name *<hostname>* to IP address *<address>*.

```
set system static-host-mapping host-name <hostname> alias <alias>
```

Create named *<alias>* for the configured static mapping for *<hostname>*. Thus the address configured as `set system static-host-mapping host-name <hostname> inet <address>` can be reached via multiple names.

Multiple aliases can be specified per host-name.

8.11.4 IP

System configuration commands

```
set system ip disable-forwarding
```

Use this command to disable IPv4 forwarding on all interfaces.

```
set system ip arp table-size <number>
```

Use this command to define the maximum number of entries to keep in the ARP cache (1024, 2048, 4096, 8192, 16384, 32768).

```
set system ip multipath layer4-hashing
```

Use this command to use Layer 4 information for IPv4 ECMP hashing.

Operational commands

show commands

See below the different parameters available for the IPv4 **show** command:

```
vyos@vyos:~$ show ip
Possible completions:
  access-list      Show all IP access-lists
  as-path-access-list
                    Show all as-path-access-lists
  bgp              Show Border Gateway Protocol (BGP) information
  community-list   Show IP community-lists
  extcommunity-list
                    Show extended IP community-lists
  forwarding       Show IP forwarding status
  groups           Show IP multicast group membership
  igmp             Show IGMP (Internet Group Management Protocol) information
  large-community-list
                    Show IP large-community-lists
  multicast        Show IP multicast
  ospf            Show IPv4 Open Shortest Path First (OSPF) routing information
  pim             Show PIM (Protocol Independent Multicast) information
  ports           Show IP ports in use by various system services
  prefix-list      Show all IP prefix-lists
  protocol         Show IP route-maps per protocol
  rip             Show Routing Information Protocol (RIP) information
  route           Show IP routes
```

reset commands

And the different IPv4 **reset** commands available:

```
vyos@vyos:~$ reset ip
Possible completions:
  arp             Reset Address Resolution Protocol (ARP) cache
  bgp            Clear Border Gateway Protocol (BGP) statistics or status
  igmp           IGMP clear commands
  multicast      IP multicast routing table
  route         Reset IP route
```

8.11.5 IPv6

System configuration commands

set system ipv6 disable

Use this command to disable assignment of IPv6 addresses on all interfaces.

set system ipv6 disable-forwarding

Use this command to disable IPv6 forwarding on all interfaces.

set system ipv6 neighbor table-size <number>

Use this command to define the maximum number of entries to keep in the Neighbor cache (1024, 2048, 4096, 8192, 16384, 32768).

set system ipv6 strict-dad

Use this command to disable IPv6 operation on interface when Duplicate Address Detection fails on Link-Local address.

set system ipv6 multipath layer4-hashing

Use this command to use Layer 4 information for ECMP hashing.

Operational commands

Show commands

show ipv6 neighbors

Use this command to show IPv6 Neighbor Discovery Protocol information.

show ipv6 groups

Use this command to show IPv6 multicast group membership.

show ipv6 forwarding

Use this command to show IPv6 forwarding status.

show ipv6 route

Use this command to show IPv6 routes.

Check the many parameters available for the *show ipv6 route* command:

```
vyos@vyos:~$ show ipv6 route
Possible completions:
<Enter>          Execute the current command
<X:X::X:X>       Show IPv6 routes of given address or prefix
<X:X::X:X/M>
bgp              Show IPv6 BGP routes
cache            Show kernel IPv6 route cache
connected        Show IPv6 connected routes
forward          Show kernel IPv6 route table
isis             Show IPv6 ISIS routes
kernel           Show IPv6 kernel routes
ospfv3           Show IPv6 OSPF6 routes
ripng            Show IPv6 RIPNG routes
static           Show IPv6 static routes
summary          Show IPv6 routes summary
table            Show IP routes in policy table
vrf              Show IPv6 routes in VRF
```

show ipv6 prefix-list

Use this command to show all IPv6 prefix lists

There are different parameters for getting prefix-list information:

```
vyos@vyos:~$ show ipv6 prefix-list
Possible completions:
<Enter>          Execute the current command
```

(continues on next page)

(continued from previous page)

<WORD>	Show specified IPv6 prefix-list
detail	Show detail of IPv6 prefix-lists
summary	Show summary of IPv6 prefix-lists

show ipv6 access-list

Use this command to show all IPv6 access lists

You can also specify which IPv6 access-list should be shown:

```
vyos@vyos:~$ show ipv6 access-list
Possible completions:
<Enter>      Execute the current command
<text>       Show specified IPv6 access-list
```

show ipv6 bgp

Use this command to show IPv6 Border Gateway Protocol information.

In addition, you can specify many other parameters to get BGP information:

```
vyos@vyos:~$ show ipv6 bgp
Possible completions:
<Enter>      Execute the current command
<X:X::X:X>   Show BGP information for given address or prefix
<X:X::X:X/M>
community    Show routes matching the communities
community-list
              Show routes matching the community-list
filter-list   Show routes conforming to the filter-list
large-community
              Show routes matching the large-community-list
large-community-list
neighbors     Show detailed information on TCP and BGP neighbor connections
prefix-list   Show routes matching the prefix-list
regex        Show routes matching the AS path regular expression
route-map     Show BGP routes matching the specified route map
summary       Show summary of BGP neighbor status
```

show ipv6 ospfv3

Use this command to get information about OSPFv3.

You can get more specific OSPFv3 information by using the parameters shown below:

```
vyos@vyos:~$ show ipv6 ospfv3
Possible completions:
<Enter>      Execute the current command
area         Show OSPFv3 spf-tree information
border-routers
              Show OSPFv3 border-router (ABR and ASBR) information
database     Show OSPFv3 Link state database information
interface     Show OSPFv3 interface information
linkstate    Show OSPFv3 linkstate routing information
neighbor     Show OSPFv3 neighbor information
redistribute  Show OSPFv3 redistribute External information
route        Show OSPFv3 routing table information
```

show ipv6 ripng

Use this command to get information about the RIPNG protocol

```
show ipv6 ripng status
```

Use this command to show the status of the RIPNG protocol

Reset commands

```
reset ipv6 bgp <address>
```

Use this command to clear Border Gateway Protocol statistics or status.

```
reset ipv6 neighbors <address | interface>
```

Use this command to reset IPv6 Neighbor Discovery Protocol cache for an address or interface.

```
reset ipv6 route cache
```

Use this command to flush the kernel IPv6 route cache. An address can be added to flush it only for that route.

8.11.6 System Display (LCD)

The system LCD LCD (Liquid-crystal display) option is for users running VyOS on hardware that features an LCD display. This is typically a small display built in an 19 inch rack-mountable appliance. Those displays are used to show runtime data.

To configure your LCD display you must first identify the used hardware, and connectivity of the display to your system. This can be any serial port (*ttySxx*) or serial via USB or even old parallel port interfaces.

Configuration

```
set system lcd device <device>
```

This is the name of the physical interface used to connect to your LCD display. Tab completion is supported and it will list you all available serial interface.

For serial via USB port information please refer to: [USB](#).

```
set system lcd model <model>
```

This is the LCD model used in your system.

At the time of this writing the following displays are supported:

- Crystalfontz CFA-533
- Crystalfontz CFA-631
- Crystalfontz CFA-633
- Crystalfontz CFA-635

Note: We can't support all displays from the beginning. If your display type is missing, please create a feature request via [Phabricator](#).

8.11.7 User Management

The default VyOS user account (*vyos*), as well as newly created user accounts, have all capabilities to configure the system. All accounts have sudo capabilities and therefore can operate as root on the system.

Both local administered and remote administered RADIUS (Remote Authentication Dial-In User Service) accounts are supported.

Local

set system login user <name> full-name "<string>"

Create new system user with username *<name>* and real-name specified by *<string>*.

set system login user <name> authentication plaintext-password <password>

Specify the plaintext password user by user *<name>* on this system. The plaintext password will be automatically transferred into a secure hashed password and not saved anywhere in plaintext.

set system login user <name> authentication encrypted-password <password>

Setup encrypted password for given username. This is useful for transferring a hashed password from system to system.

Key Based Authentication

It is highly recommended to use SSH key authentication. By default there is only one user (*vyos*), and you can assign any number of keys to that user. You can generate a ssh key with the *ssh-keygen* command on your local machine, which will (by default) save it as *~/.ssh/id_rsa.pub*.

Every SSH key comes in three parts:

```
ssh-rsa AAAAB3NzaC1yc2EAAAABAA...VBD5lKwEWB username@host.example.com
```

Only the type (*ssh-rsa*) and the key (*AAAAB3N...*) are used. Note that the key will usually be several hundred characters long, and you will need to copy and paste it. Some terminal emulators may accidentally split this over several lines. Be attentive when you paste it that it only pastes as a single line. The third part is simply an identifier, and is for your own reference.

set system login user <username> authentication public-keys <identifier> key <key>

Assign the SSH public key portion *<key>* identified by per-key *<identifier>* to the local user *<username>*.

set system login user <username> authentication public-keys <identifier> type <type>

Every SSH public key portion referenced by *<identifier>* requires the configuration of the *<type>* of public-key used. This type can be any of:

- *ecdsa-sha2-nistp256*
- *ecdsa-sha2-nistp384*
- *ecdsa-sha2-nistp521*
- *ssh-dss*
- *ssh-ed25519*
- *ssh-rsa*

Note: You can assign multiple keys to the same user by using a unique identifier per SSH key.

loadkey <username> <location>

Deprecation notice: `loadkey` has been deprecated in favour of `generate public-key-commands` and will be removed in a future version. See [SSH](#).

SSH keys can not only be specified on the command-line but also loaded for a given user with <username> from a file pointed to by <location>. Keys can be either loaded from local filesystem or any given remote location using one of the following URIs (Uniform Resource Identifier):

- <file> - Load from file on local filesystem path
- `scp://<user>@<host>:/<file>` - Load via SCP from remote machine
- `sftp://<user>@<host>/<file>` - Load via SFTP from remote machine
- `ftp://<user>@<host>/<file>` - Load via FTP from remote machine
- `http://<host>/<file>` - Load via HTTP from remote machine
- `tftp://<host>/<file>` - Load via TFTP from remote machine

Example

In the following example, both *User1* and *User2* will be able to SSH into VyOS as user `vyos` using their very own keys.

```
set system login user vyos authentication public-keys 'User1' key "AAAAB3Nz...KwEW"
set system login user vyos authentication public-keys 'User1' type ssh-rsa
set system login user vyos authentication public-keys 'User2' key "AAAAQ39x...fbV3"
set system login user vyos authentication public-keys 'User2' type ssh-rsa
```

RADIUS

In large deployments it is not reasonable to configure each user individually on every system. VyOS supports using RADIUS servers as backend for user authentication.

Configuration

set system login radius server <address> secret <secret>

Specify the <address> of the RADIUS server user with the pre-shared-secret given in <secret>. Multiple servers can be specified.

set system login radius server <address> port <port>

Configure the discrete port under which the RADIUS server can be reached. This defaults to 1812.

set system login radius server <address> timeout <timeout>

Setup the <timeout> in seconds when querying the RADIUS server.

set system login radius server <address> disable

Temporary disable this RADIUS server. It won't be queried.

set system login radius source-address <address>

RADIUS servers could be hardened by only allowing certain IP addresses to connect. As of this the source address of each RADIUS query can be configured. If this is not set, incoming connections to the RADIUS server will use the nearest interface address pointing towards the server - making it error prone on e.g. OSPF networks when a link fails and a backup route is taken.

Hint: If you want to have admin users to authenticate via RADIUS it is essential to send the `Cisco-AV-Pair shell:priv-lvl=15` attribute. Without the attribute you will only get regular, non privileged, system users.

Login Banner

You are able to set post-login or pre-login banner messages to display certain information for this system.

set system login banner pre-login <message>

Configure <message> which is shown during SSH connect and before a user is logged in.

set system login banner post-login <message>

Configure <message> which is shown after user has logged in to the system.

Note: To create a new line in your login message you need to escape the new line character by using `\\n`.

8.11.8 System DNS

Warning: If you are configuring a VRF for management purposes, there is currently no way to force system DNS traffic via a specific VRF.

This section describes configuring DNS on the system, namely:

- DNS name servers
- Domain search order

DNS name servers

set system name-server <address>

Use this command to specify a DNS server for the system to be used for DNS lookups. More than one DNS server can be added, configuring one at a time. Both IPv4 and IPv6 addresses are supported.

Example

In this example, some *OpenNIC* servers are used, two IPv4 addresses and two IPv6 addresses:

```
set system name-server 176.9.37.132
set system name-server 195.10.195.195
set system name-server 2a01:4f8:161:3441::1
set system name-server 2a00:f826:8:2::195
```

Domain search order

In order for the system to use and complete unqualified host names, a list can be defined which will be used for domain searches.

set system domain-search domain <domain>

Use this command to define domains, one at a time, so that the system uses them to complete unqualified host names. Maximum: 6 entries.

Note: Domain names can include letters, numbers, hyphens and periods with a maximum length of 253 characters.

Example

The system is configured to attempt domain completion in the following order: vyos.io (first), vyos.net (second) and vyos.network (last):

```
set system domain-search domain vyos.io
set system domain-search domain vyos.net
set system domain-search domain vyos.network
```

8.11.9 NTP

NTP (NETWORK TIME PROTOCOL) is a networking protocol for clock synchronization between computer systems over packet-switched, variable-latency data networks. In operation since before 1985, NTP is one of the oldest Internet protocols in current use.

NTP is intended to synchronize all participating computers to within a few milliseconds of UTC (Coordinated Universal Time). It uses the intersection algorithm, a modified version of Marzullo's algorithm, to select accurate time servers and is designed to mitigate the effects of variable network latency. NTP can usually maintain time to within tens of milliseconds over the public Internet, and can achieve better than one millisecond accuracy in local area networks under ideal conditions. Asymmetric routes and network congestion can cause errors of 100 ms or more.

The protocol is usually described in terms of a client-server model, but can as easily be used in peer-to-peer relationships where both peers consider the other to be a potential time source. Implementations send and receive timestamps using UDP (User Datagram Protocol) on port number 123.

NTP supplies a warning of any impending leap second adjustment, but no information about local time zones or daylight saving time is transmitted.

The current protocol is version 4 (NTPv4), which is a proposed standard as documented in [RFC 5905](#). It is backward compatible with version 3, specified in [RFC 1305](#).

Configuration

set system ntp server <address>

Configure one or more servers for synchronisation. Server name can be either an IP address or FQDN (Fully Qualified Domain Name).

There are 3 default NTP server set. You are able to change them.

- 0.pool.ntp.org
- 1.pool.ntp.org

- 2.pool.ntp.org

set system ntp server <address> <noselect | pool | preempt | prefer>

Configure one or more attributes to the given NTP server.

- `noselect` marks the server as unused, except for display purposes. The server is discarded by the selection algorithm.
- `pool` mobilizes persistent client mode association with a number of remote servers.
- `preempt` a preemptable association is expendable.
- `prefer` marks the server as preferred. All other things being equal, this host will be chosen for synchronization among a set of correctly operating hosts.

set system ntp listen-address <address>

NTP process will only listen on the specified IP address. You must specify the <address> and optionally the permitted clients. Multiple listen addresses can be configured.

set system ntp allow-clients address <address>

List of networks or client addresses permitted to contact this NTP server.

Multiple networks can be configured.

set system ntp vrf <name>

Specify name of the VRF instance.

8.11.10 Option

This chapter describe the possibilities of advanced system behavior.

General

set system option ctrl-alt-delete <ignore | reboot | poweroff>

Action which will be run once the ctrl-alt-del keystroke is received.

set system option reboot-on-panic

Automatically reboot system on kernel panic after 60 seconds.

set system option startup-beep

Play an audible beep to the system speaker when system is ready.

HTTP client

set system option http-client source-address <address>

Several commands utilize cURL to initiate transfers. Configure the local source IPv4/IPv6 address used for all cURL operations.

set system option http-client source-interface <interface>

Several commands utilize curl to initiate transfers. Configure the local source interface used for all CURL operations.

Note: *source-address* and *source-interface* can not be used at the same time.

Keyboard Layout

When starting a VyOS live system (the installation CD) the configured keyboard layout defaults to US. As this might not suite everyones use case you can adjust the used keyboard layout on the system console.

set system option keyboard-layout <us | fr | de | fi | no | dk>

Change system keyboard layout to given language.

Defaults to `us`.

Note: Changing the keymap only has an effect on the system console, using SSH or Serial remote access to the device is not affected as the keyboard layout here corresponds to your access system.

Performance

As more and more routers run on Hypervisors, expecially with a NOS (Network Operating System) as VyOS, it makes fewer and fewer sense to use static resource bindings like `smp-affinity` as present in VyOS 1.2 and earlier to pin certain interrupt handlers to specific CPUs.

We now utilize *tuned* for dynamic resource balancing based on profiles.

See also:

<https://access.redhat.com/sites/default/files/attachments/201501-perf-brief-low-latency-tuning-rhel7-v2.1.pdf>

set system option performance < throughput | latency >

Configure one of the predefined system performance profiles.

- **throughput:** A server profile focused on improving network throughput. This profile favors performance over power savings by setting `intel_pstate` and `max_perf_pct=100` and increasing kernel network buffer sizes.

It enables transparent huge pages, and uses `cpupower` to set the performance `cpufreq` governor. It also sets `kernel.sched_min_granularity_ns` to 10 us, `kernel.sched_wakeup_granularity_ns` to 15 uss, and `vm.dirty_ratio` to 40%.

- **latency:** A server profile focused on lowering network latency. This profile favors performance over power savings by setting `intel_pstate` and `min_perf_pct=100`.

It disables transparent huge pages, and automatic NUMA balancing. It also uses `cpupower` to set the performance `cpufreq` governor, and requests a `cpu_dma_latency` value of 1. It also sets `busy_read` and `busy_poll` times to 50 us, and `tcp_fastopen` to 3.

8.11.11 System Proxy

Some IT environments require the use of a proxy to connect to the Internet. Without this configuration VyOS updates could not be installed directly by using the `add system image` command (*Update VyOS*).

set system proxy url <url>

Set proxy for all connections initiated by VyOS, including HTTP, HTTPS, and FTP (anonymous ftp).

```
set system proxy port <port>
```

Configure proxy port if it does not listen to the default port 80.

```
set system proxy username <username>
```

Some proxys require/support the “basic” HTTP authentication scheme as per [RFC 7617](#), thus a username can be configured.

```
set system proxy password <password>
```

Some proxys require/support the “basic” HTTP authentication scheme as per [RFC 7617](#), thus a password can be configured.

8.11.12 Syslog

Per default VyOSs has minimal syslog logging enabled which is stored and rotated locally. Errors will be always logged to a local file, which includes *local7* error messages, emergency messages will be sent to the console, too.

To configure syslog, you need to switch into configuration mode.

Logging

Syslog supports logging to multiple targets, those targets could be a plain file on your VyOS installation itself, a serial console or a remote syslog server which is reached via IP (Internet Protocol) UDP/TCP.

Console

```
set system syslog console facility <keyword> level <keyword>
```

Log syslog messages to `/dev/console`, for an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

Custom File

```
set system syslog file <filename> facility <keyword> level <keyword>
```

Log syslog messages to file specified via `<filename>`, for an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

```
set system syslog file <filename> archive size <size>
```

Syslog will write `<size>` kilobytes into the file specified by `<filename>`. After this limit has been reached, the custom file is “rotated” by logrotate and a new custom file is created.

```
set system syslog file <filename> archive file <number>
```

Syslog uses logrotate to rotate logfiles after a number of gives bytes. We keep as many as `<number>` rotated file before they are deleted on the system.

Remote Host

Logging to a remote host leaves the local logging configuration intact, it can be configured in parallel to a custom file or console logging. You can log to multiple hosts at the same time, using either TCP or UDP. The default is sending the messages via port 514/UDP.

```
set system syslog host <address> facility <keyword> level <keyword>
```

Log syslog messages to remote host specified by <address>. The address can be specified by either FQDN or IP address. For an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

```
set system syslog host <address> facility <keyword> protocol <udp|tcp>
```

Configure protocol used for communication to remote syslog host. This can be either UDP or TCP.

Local User Account

```
set system syslog user <username> facility <keyword> level <keyword>
```

If logging to a local user account is configured, all defined log messages are display on the console if the local user is logged in, if the user is not logged in, no messages are being displayed. For an explanation on *Facilities* keywords and *Severity Level* keywords see tables below.

Facilities

List of facilities used by syslog. Most facilities names are self explanatory. Facilities local0 - local7 common usage is f.e. as network logs facilities for nodes and network equipment. Generally it depends on the situation how to classify logs and put them to facilities. See facilities more as a tool rather than a directive to follow.

Facilities can be adjusted to meet the needs of the user:

Facility Code	Keyword	Description
	all	All facilities
0	kern	Kernel messages
1	user	User-level messages
2	mail	Mail system
3	daemon	System daemons
4	auth	Security/authentication messages
5	syslog	Messages generated internally by syslogd
6	lpr	Line printer subsystem
7	news	Network news subsystem
8	uucp	UUCP subsystem
9	cron	Clock daemon
10	security	Security/authentication messages
11	ftp	FTP daemon
12	ntp	NTP subsystem
13	logaudit	Log audit
14	logalert	Log alert
15	clock	clock daemon (note 2)
16	local0	local use 0 (local0)
17	local1	local use 1 (local1)
18	local2	local use 2 (local2)
19	local3	local use 3 (local3)
20	local4	local use 4 (local4)
21	local5	local use 5 (local5)
22	local6	use 6 (local6)
23	local7	local use 7 (local7)

Severity Level

Value	Severity	Key-word	Description
		all	Log everything
0	Emergency	emerg	System is unusable - a panic condition
1	Alert	alert	Action must be taken immediately - A condition that should be corrected immediately, such as a corrupted system database.
2	Critical	crit	Critical conditions - e.g. hard drive errors.
3	Error	err	Error conditions
4	Warning	warning	Warning conditions
5	Notice	notice	Normal but significant conditions - conditions that are not error conditions, but that may require special handling.
6	Informational	info	Informational messages
7	Debug	debug	Debug-level messages - Messages that contain information normally of use only when debugging a program.

Display Logs

show log [all | authorization | cluster | conntrack-sync | ...]

Display log files of given category on the console. Use tab completion to get a list of available categories. Those categories could be: all, authorization, cluster, conntrack-sync, dhcp, directory, dns, file, firewall, https, image, lldp, nat, openvpn, snmp, tail, vpn, vrrp

If no option is specified, this defaults to *all*.

show log image <name> [all | authorization | directory | file <file name> | tail <lines>]

Log messages from a specified image can be displayed on the console. Details of allowed parameters:

all	Display contents of all master log files of the specified image
authorization	Display all authorization attempts of the specified image
directory	Display list of all user-defined log files of the specified image
file <file name>	Display contents of a specified user-defined log file of the specified image
tail	Display last lines of the system log of the specified image
<lines>	Number of lines to be displayed, default 10

When no options/parameters are used, the contents of the main syslog file are displayed.

Hint: Use `show log | strip-private` if you want to hide private data when sharing your logs.

Delete Logs

delete log file <text>

Deletes the specified user-defined file <text> in the /var/log/user directory

Note that deleting the log file does not stop the system from logging events. If you use this command while the system is logging events, old log events will be deleted, but events after the delete operation will be recorded in the new file. To delete the file altogether, first delete logging to the file using system syslog *Custom File* command, and then delete the file.

8.11.13 Task Scheduler

The task scheduler allows you to execute tasks on a given schedule. It makes use of UNIX *cron*.

Note: All scripts executed this way are executed as root user - this may be dangerous. Together with *Command Scripting* this can be used for automating (re-)configuration.

set system task-scheduler task <task> interval <interval>

Specify the time interval when <task> should be executed. The interval is specified as number with one of the following suffixes:

- none - Execution interval in minutes
- m - Execution interval in minutes
- h - Execution interval in hours
- d - Execution interval in days

Note: If suffix is omitted, minutes are implied.

set system task-scheduler task <task> crontab-spec <spec>

Set execution time in common *cron* time format. A cron <spec> of 30 */6 * * * would execute the <task> at minute 30 past every 6th hour.

set system task-scheduler task <task> executable path <path>

Specify absolute <path> to script which will be run when <task> is executed.

set system task-scheduler task <task> executable arguments <args>

Arguments which will be passed to the executable.

8.11.14 Time Zone

Time Zone setting is very important as e.g all your logfile entries will be based on the configured zone. Without proper time zone configuration it will be very difficult to compare logfiles from different systems.

set system time-zone <timezone>

Specify the systems <timezone> as the Region/Location that best defines your location. For example, specifying US/Pacific sets the time zone to US Pacific time.

Command completion can be used to list available time zones. The adjustment for daylight time will take place automatically based on the time of year.

8.11.15 Default Gateway/Route

In the past (VyOS 1.1) used a gateway-address configured under the system tree (`set system gateway-address <address>`), this is no longer supported and existing configurations are migrated to the new CLI command.

Configuration

set protocols static route 0.0.0.0/0 next-hop <address>

Specify static route into the routing table sending all non local traffic to the nexthop address *<address>*.

delete protocols static route 0.0.0.0/0

Delete default route from the system.

Operation

show ip route 0.0.0.0

Show routing table entry for the default route.

```
vyos@vyos:~$ show ip route 0.0.0.0
Routing entry for 0.0.0.0/0
  Known via "static", distance 10, metric 0, best
  Last update 09:46:30 ago
  * 172.18.201.254, via eth0.201
```

See also:

Configuration of *Static*

8.11.16 Event Handler

Event handler allows you to execute scripts when a string that matches a regex appears in a text stream (e.g. log file).

It uses “feeds” (output of commands, or a named pipes) and “policies” that define what to execute if a regex is matched.

```
system
event-handler
  feed <name>
  description <feed description>
  policy <policy name>
  source
    preset
    syslog # Use the syslog logs for feed
    custom
    command <command to execute> # E.g. "tail -f /var/log/somelogfile"
    named-pipe <path to a names pipe>
  policy <policy name>
  description <policy description>
  event <event name>
    description <event description>
    pattern <regex>
    run <command to run>
```

In this small example a script runs every time a login failed and an interface goes down

```
vyos@vyos# show system event-handler
feed Syslog {
    policy MyPolicy
    source {
        preset syslog
    }
}
policy MyPolicy {
    description "Test policy"
    event BadThingsHappened {
        pattern "authentication failure"
        pattern "interface \.* index \d+ \.* DOWN.*"
        run /config/scripts/email-to-admin
    }
}
```

8.12 Traffic Policy

8.12.1 QoS

The generic name of Quality of Service or Traffic Control involves things like shaping traffic, scheduling or dropping packets, which are the kind of things you may want to play with when you have, for instance, a bandwidth bottleneck in a link and you want to somehow prioritize some type of traffic over another.

`tc` is a powerful tool for Traffic Control found at the Linux kernel. However, its configuration is often considered a cumbersome task. Fortunately, VyOS eases the job through its CLI, while using `tc` as backend.

How to make it work

In order to have VyOS Traffic Control working you need to follow 2 steps:

1. **Create a traffic policy.**
2. **Apply the traffic policy to an interface ingress or egress.**

But before learning to configure your policy, we will warn you about the different units you can use and also show you what *classes* are and how they work, as some policies may require you to configure them.

Units

When configuring your traffic policy, you will have to set data rate values, watch out the units you are managing, it is easy to get confused with the different prefixes and suffixes you can use. VyOS will always show you the different units you can use.

Prefixes

They can be **decimal** prefixes.

kbit	(10 ³)	kilobit per second
mbit	(10 ⁶)	megabit per second
gbit	(10 ⁹)	gigabit per second

(continues on next page)

(continued from previous page)

tbit	(10 ¹²)	terabit per second
kbps	(8*10 ³)	kilobyte per second
mbps	(8*10 ⁶)	megabyte per second
gbps	(8*10 ⁹)	gigabyte per second
tbps	(8*10 ¹²)	terabyte per second

Or **binary** prefixes.

kibit	(2 ¹⁰ = 1024)	kibibit per second
mibit	(2 ²⁰ = 1024 ²)	mebibit per second
gibit	(2 ³⁰ = 1024 ³)	gibibit per second
tbit	(2 ⁴⁰ = 1024 ⁴)	tebibit per second
kibps	(1024*8)	kibibyte (KiB) per second
mibps	(1024 ² *8)	mebibyte (MiB) per second
gibps	(1024 ³ *8)	gibibyte (GiB) per second
tibps	(1024 ⁴ *8)	tebibyte (TiB) per second

Suffixes

A *bit* is written as **bit**,

kbit	(kilobits per second)
mbit	(megabits per second)
gbit	(gigabits per second)
tbit	(terabits per second)

while a *byte* is written as a single **b**.

kbps	(kilobytes per second)
mbps	(megabytes per second)
gbps	(gigabytes per second)

Classes

In the [Creating a traffic policy](#) section you will see that some of the policies use *classes*. Those policies let you distribute traffic into different classes according to different parameters you can choose. So, a class is just a specific type of traffic you select.

The ultimate goal of classifying traffic is to give each class a different treatment.

Matching traffic

In order to define which traffic goes into which class, you define filters (that is, the matching criteria). Packets go through these matching rules (as in the rules of a firewall) and, if a packet matches the filter, it is assigned to that class.

In VyOS, a class is identified by a number you can choose when configuring it.

Note: The meaning of the Class ID is not the same for every type of policy. Normally policies just need a meaningless number to identify a class (Class ID), but that does not apply to every policy. The the number of a class in a Priority

Queue it does not only identify it, it also defines its priority.

```
set traffic-policy <policy> <policy-name> class <class-ID> match <class-matching-rule-
↪name>
```

In the command above, we set the type of policy we are going to work with and the name we choose for it; a class (so that we can differentiate some traffic) and an identifiable number for that class; then we configure a matching rule (or filter) and a name for it.

A class can have multiple match filters:

```
set traffic-policy shaper MY-SHAPER class 30 match HTTP
set traffic-policy shaper MY-SHAPER class 30 match HTTPs
```

A match filter can contain multiple criteria and will match traffic if all those criteria are true.

For example:

```
set traffic-policy shaper MY-SHAPER class 30 match HTTP ip protocol tcp
set traffic-policy shaper MY-SHAPER class 30 match HTTP ip source port 80
```

This will match TCP traffic with source port 80.

There are many parameters you will be able to use in order to match the traffic you want for a class:

- **Ethernet (protocol, destination address or source address)**
- **Interface name**
- **IPv4 (DSCP value, maximum packet length, protocol, source address, destination address, source port, destination port or TCP flags)**
- **IPv6 (DSCP value, maximum payload length, protocol, source address, destination address, source port, destination port or TCP flags)**
- **Firewall mark**
- **VLAN ID**

When configuring your filter, you can use the Tab key to see the many different parameters you can configure.

```
vyos@vyos# set traffic-policy shaper MY-SHAPER class 30 match MY-FIRST-FILTER
Possible completions:
  description  Description for this match
> ether        Ethernet header match
  interface    Interface name for this match
> ip           Match IP protocol header
> ipv6         Match IPV6 header
  mark         Match on mark applied by firewall
  vif          Virtual Local Area Network (VLAN) ID for this match
```

As shown in the example above, one of the possibilities to match packets is based on marks done by the firewall, [that can give you a great deal of flexibility](#).

You can also write a description for a filter:

```
set traffic-policy shaper MY-SHAPER class 30 match MY-FIRST-FILTER description "My_
↪filter description"
```

Note: An IPv4 TCP filter will only match packets with an IPv4 header length of 20 bytes (which is the majority of IPv4 packets anyway).

Note: IPv6 TCP filters will only match IPv6 packets with no header extension, see https://en.wikipedia.org/wiki/IPv6_packet#Extension_headers

Default

Often you will also have to configure your *default* traffic in the same way you do with a class. *Default* can be considered a class as it behaves like that. It contains any traffic that did not match any of the defined classes, so it is like an open class, a class without matching filters.

Class treatment

Once a class has a filter configured, you will also have to define what you want to do with the traffic of that class, what specific Traffic-Control treatment you want to give it. You will have different possibilities depending on the Traffic Policy you are configuring.

```
vyos@vyos# set traffic-policy shaper MY-SHAPER class 30
Possible completions:
  bandwidth      Bandwidth used for this class
  burst          Burst size for this class (default: 15kb)
  ceiling        Bandwidth limit for this class
  codel-quantum  fq-codel - Number of bytes used as 'deficit' (default 1514)
  description    Description for this traffic class
  flows          fq-codel - Number of flows (default 1024)
  interval       fq-codel - Interval (milliseconds) used to measure the delay (default
->100)
+> match        Class matching rule name
  priority       Priority for usage of excess bandwidth
  queue-limit    Maximum queue size (packets)
  queue-type     Queue type for this class
  set-dscp       Change the Differentiated Services (DiffServ) field in the IP header
  target         fq-codel - Acceptable minimum queue delay (milliseconds)
```

For instance, with `set traffic-policy shaper MY-SHAPER class 30 set-dscp EF` you would be modifying the DSCP field value of packets in that class to Expedite Forwarding.

DSCP values as per [RFC 2474](#) and [RFC 4595](#):

Binary value	Configured value	Drop rate	Description
101110	46	•	Expedited forwarding (EF)
000000	0	•	Best effort traffic, default
001010	10	Low	Assured Forwarding(AF) 11
001100	12	Medium	Assured Forwarding(AF) 12
001110	14	High	Assured Forwarding(AF) 13
010010	18	Low	Assured Forwarding(AF) 21
010100	20	Medium	Assured Forwarding(AF) 22
010110	22	High	Assured Forwarding(AF) 23
011010	26	Low	Assured Forwarding(AF) 31
011100	28	Medium	Assured Forwarding(AF) 32
011110	30	High	Assured Forwarding(AF) 33
100010	34	Low	Assured Forwarding(AF) 41
100100	36	Medium	Assured Forwarding(AF) 42
100110	38	High	Assured Forwarding(AF) 43

Embedding one policy into another one

Often we need to embed one policy into another one. It is possible to do so on classful policies, by attaching a new policy into a class. For instance, you might want to apply different policies to the different classes of a Round-Robin policy you have configured.

A common example is the case of some policies which, in order to be effective, they need to be applied to an interface that is directly connected where the bottleneck is. If your router is not directly connected to the bottleneck, but some hop before it, you can emulate the bottleneck by embedding your non-shaping policy into a classful shaping one so that it takes effect.

You can configure a policy into a class through the `queue-type` setting.

```
set traffic-policy shaper FQ-SHAPER bandwidth 4gbit
set traffic-policy shaper FQ-SHAPER default bandwidth 100%
set traffic-policy shaper FQ-SHAPER default queue-type fq-code1
```

As shown in the last command of the example above, the `queue-type` setting allows these combinations. You will be able to use it in many policies.

Note: Some policies already include other embedded policies inside. That is the case of *Shaper*: each of its classes

use fair-queue unless you change it.

Creating a traffic policy

VyOS lets you control traffic in many different ways, here we will cover every possibility. You can configure as many policies as you want, but you will only be able to apply one policy per interface and direction (inbound or outbound).

Some policies can be combined, you will be able to *embed* a different policy that will be applied to a class of the main policy.

Hint: If you are looking for a policy for your outbound traffic but you don't know which one you need and you don't want to go through every possible policy shown here, **our bet is that highly likely you are looking for a *Shaper* policy and you want to *set its queues* as FQ-CoDel.**

Drop Tail

Queueing discipline: PFIFO (Packet First In First Out).

Applies to: Outbound traffic.

This the simplest queue possible you can apply to your traffic. Traffic must go through a finite queue before it is actually sent. You must define how many packets that queue can contain.

When a packet is to be sent, it will have to go through that queue, so the packet will be placed at the tail of it. When the packet completely goes through it, it will be dequeued emptying its place in the queue and being eventually handed to the NIC to be actually sent out.

Despite the Drop-Tail policy does not slow down packets, if many packets are to be sent, they could get dropped when trying to get enqueued at the tail. This can happen if the queue has still not been able to release enough packets from its head.

This is the policy that requires the lowest resources for the same amount of traffic. But **very likely you do not need it as you cannot get much from it. Sometimes it is used just to enable logging.**

set traffic-policy drop-tail <policy-name> queue-limit <number-of-packets>

Use this command to configure a drop-tail policy (PFIFO). Choose a unique name for this policy and the size of the queue by setting the number of packets it can contain (maximum 4294967295).

Fair Queue

Queueing discipline: SFQ (Stochastic Fairness Queuing).

Applies to: Outbound traffic.

Fair Queue is a work-conserving scheduler which schedules the transmission of packets based on flows, that is, it balances traffic distributing it through different sub-queues in order to ensure fairness so that each flow is able to send data in turn, preventing any single one from drowning out the rest.

set traffic-policy fair-queue <policy-name>

Use this command to create a Fair-Queue policy and give it a name. It is based on the Stochastic Fairness Queueing and can be applied to outbound traffic.

In order to separate traffic, Fair Queue uses a classifier based on source address, destination address and source port. The algorithm enqueues packets to hash buckets based on those three parameters. Each of these buckets should represent a unique flow. Because multiple flows may get hashed to the same bucket, the hashing algorithm is perturbed at configurable intervals so that the unfairness lasts only for a short while. Perturbation may however cause some inadvertent packet reordering to occur. An advisable value could be 10 seconds.

One of the uses of Fair Queue might be the mitigation of Denial of Service attacks.

set traffic-policy fair-queue <policy-name> hash-interval <seconds>

Use this command to define a Fair-Queue policy, based on the Stochastic Fairness Queueing, and set the number of seconds at which a new queue algorithm perturbation will occur (maximum 4294967295).

When dequeuing, each hash-bucket with data is queried in a round robin fashion. You can configure the length of the queue.

set traffic-policy fair-queue <policy-name> queue-limit <limit>

Use this command to define a Fair-Queue policy, based on the Stochastic Fairness Queueing, and set the number of maximum packets allowed to wait in the queue. Any other packet will be dropped.

Note: Fair Queue is a non-shaping (work-conserving) policy, so it will only be useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and Fair Queue will have no effect. If there is bandwidth available on the physical link, you can *embed* Fair-Queue into a classful shaping policy to make sure it owns the queue.

FQ-CoDel

Queueing discipline Fair/Flow Queue CoDel.

Applies to: Outbound Traffic.

The FQ-CoDel policy distributes the traffic into 1024 FIFO queues and tries to provide good service between all of them. It also tries to keep the length of all the queues short.

FQ-CoDel fights bufferbloat and reduces latency without the need of complex configurations. It has become the new default Queueing Discipline for the interfaces of some GNU/Linux distributions.

It uses a stochastic model to classify incoming packets into different flows and is used to provide a fair share of the bandwidth to all the flows using the queue. Each flow is managed by the CoDel queueing discipline. Reordering within a flow is avoided since CoDel internally uses a FIFO queue.

FQ-CoDel is based on a modified Deficit Round Robin (*DRR*) queue scheduler with the CoDel Active Queue Management (AQM) algorithm operating on each queue.

Note: FQ-CoDel is a non-shaping (work-conserving) policy, so it will only be useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and FQ-CoDel will have no effect. If there is bandwidth available on the physical link, you can *embed* FQ-CoDel into a classful shaping policy to make sure it owns the queue. If you are not sure if you need to embed your FQ-CoDel policy into a Shaper, do it.

FQ-CoDel is tuned to run ok with its default parameters at 10Gbit speeds. It might work ok too at other speeds without configuring anything, but here we will explain some cases when you might want to tune its parameters.

When running it at 1Gbit and lower, you may want to reduce the *queue-limit* to 1000 packets or less. In rates like 10Mbit, you may want to set it to 600 packets.

If you are using FQ-CoDel embedded into *Shaper* and you have large rates (100Mbit and above), you may consider increasing *quantum* to 8000 or higher so that the scheduler saves CPU.

On low rates (below 40Mbit) you may want to tune *quantum* down to something like 300 bytes.

At very low rates (below 3Mbit), besides tuning *quantum* (300 keeps being ok) you may also want to increase *target* to something like 15ms and increase *interval* to something around 150 ms.

set traffic-policy fq-codel <policy name> codel-quantum <bytes>

Use this command to configure an fq-codel policy, set its name and the maximum number of bytes (default: 1514) to be dequeued from a queue at once.

set traffic-policy fq-codel <policy name> flows <number-of-flows>

Use this command to configure an fq-codel policy, set its name and the number of sub-queues (default: 1024) into which packets are classified.

set traffic-policy fq-codel <policy name> interval <milliseconds>

Use this command to configure an fq-codel policy, set its name and the time period used by the control loop of CoDel to detect when a persistent queue is developing, ensuring that the measured minimum delay does not become too stale (default: 100ms).

set traffic-policy fq-codel <policy-name> queue-limit <number-of-packets>`

Use this command to configure an fq-codel policy, set its name, and define a hard limit on the real queue size. When this limit is reached, new packets are dropped (default: 10240 packets).

set traffic-policy fq-codel <policy-name> target <milliseconds>`

Use this command to configure an fq-codel policy, set its name, and define the acceptable minimum standing/persistent queue delay. This minimum delay is identified by tracking the local minimum queue delay that packets experience (default: 5ms).

Example

A simple example of an FQ-CoDel policy working inside a Shaper one.

```
set traffic-policy shaper FQ-CODEL-SHAPER bandwidth 2gbit
set traffic-policy shaper FQ-CODEL-SHAPER default bandwidth 100%
set traffic-policy shaper FQ-CODEL-SHAPER default queue-type fq-codel
```

Limiter

Queueing discipline: Ingress policer.

Applies to: Inbound traffic.

Limiter is one of those policies that uses *classes* (Ingress qdisc is actually a classless policy but filters do work in it).

The limiter performs basic ingress policing of traffic flows. Multiple classes of traffic can be defined and traffic limits can be applied to each class. Although the policer uses a token bucket mechanism internally, it does not have the capability to delay a packet as a shaping mechanism does. Traffic exceeding the defined bandwidth limits is directly dropped. A maximum allowed burst can be configured too.

You can configure classes (up to 4090) with different settings and a default policy which will be applied to any traffic not matching any of the configured classes.

Note: In the case you want to apply some kind of **shaping** to your **inbound** traffic, check the *ingress-shaping* section.

```
set traffic-policy limiter <policy-name> class <class ID> match <match-name>  
description <description>
```

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090), a class matching rule name and its description.

Once the matching rules are set for a class, you can start configuring how you want matching traffic to behave.

```
set traffic-policy limiter <policy-name> class <class-ID> bandwidth <rate>
```

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090) and the maximum allowed bandwidth for this class.

```
set traffic-policy limiter <policy-name> class <class-ID> burst <burst-size>
```

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090) and the burst size in bytes for this class (default: 15).

```
set traffic-policy limiter <policy-name> default bandwidth <rate>
```

Use this command to configure an Ingress Policer, defining its name and the maximum allowed bandwidth for its default policy.

```
set traffic-policy limiter <policy-name> default burst <burst-size>
```

Use this command to configure an Ingress Policer, defining its name and the burst size in bytes (default: 15) for its default policy.

```
set traffic-policy limiter <policy-name> class <class ID> priority <value>
```

Use this command to configure an Ingress Policer, defining its name, a class identifier (1-4090), and the priority (0-20, default 20) in which the rule is evaluated (the lower the number, the higher the priority).

Network Emulator

Queueing discipline: netem (Network Emulator) + TBF (Token Bucket Filter).

Applies to: Outbound traffic.

VyOS Network Emulator policy emulates the conditions you can suffer in a real network. You will be able to configure things like rate, burst, delay, packet loss, packet corruption or packet reordering.

This could be helpful if you want to test how an application behaves under certain network conditions.

```
set traffic-policy network-emulator <policy-name> bandwidth <rate>
```

Use this command to configure the maximum rate at which traffic will be shaped in a Network Emulator policy. Define the name of the policy and the rate.

```
set traffic-policy network-emulator <policy-name> burst <burst-size>
```

Use this command to configure the burst size of the traffic in a Network Emulator policy. Define the name of the Network Emulator policy and its traffic burst size (it will be configured through the Token Bucket Filter qdisc). Default: 15kb. It will only take effect if you have configured its bandwidth too.

```
set traffic-policy network-emulator <policy-name> network-delay <delay>
```

Use this command to configure a Network Emulator policy defining its name and the fixed amount of time you want to add to all packet going out of the interface. The latency will be added through the Token Bucket Filter qdisc. It will only take effect if you have configured its bandwidth too. You can use secs, ms and us. Default: 50ms.

set traffic-policy network-emulator <policy-name> packet-corruption <percent>

Use this command to emulate noise in a Network Emulator policy. Set the policy name and the percentage of corrupted packets you want. A random error will be introduced in a random position for the chosen percent of packets.

set traffic-policy network-emulator <policy-name> packet-loss <percent>

Use this command to emulate packet-loss conditions in a Network Emulator policy. Set the policy name and the percentage of loss packets your traffic will suffer.

set traffic-policy network-emulator <policy-name> packet-reordering <percent>

Use this command to emulate packet-reordering conditions in a Network Emulator policy. Set the policy name and the percentage of reordered packets your traffic will suffer.

set traffic-policy network-emulator <policy-name> queue-limit <limit>

Use this command to define the length of the queue of your Network Emulator policy. Set the policy name and the maximum number of packets (1-4294967295) the queue may hold queued at a time.

Priority Queue

Queueing discipline: PRIO.

Applies to: Outbound traffic.

The Priority Queue is a classful scheduling policy. It does not delay packets (Priority Queue is not a shaping policy), it simply dequeues packets according to their priority.

Note: Priority Queue, as other non-shaping policies, is only useful if your outgoing interface is really full. If it is not, VyOS will not own the queue and Priority Queue will have no effect. If there is bandwidth available on the physical link, you can *embed* Priority Queue into a classful shaping policy to make sure it owns the queue. In that case packets can be prioritized based on DSCP.

Up to seven queues -defined as *classes* with different priorities- can be configured. Packets are placed into queues based on associated match criteria. Packets are transmitted from the queues in priority order. If classes with a higher priority are being filled with packets continuously, packets from lower priority classes will only be transmitted after traffic volume from higher priority classes decreases.

Note: In Priority Queue we do not define clases with a meaningless class ID number but with a class priority number (1-7). The lower the number, the higher the priority.

As with other policies, you can define different type of matching rules for your classes:

```
vyos@vyos# set traffic-policy priority-queue MY-PRIO class 3 match MY-MATCH-RULE
Possible completions:
  description  Description for this match
  > ether      Ethernet header match
  interface    Interface name for this match
```

(continues on next page)

(continued from previous page)

```

> ip          Match IP protocol header
> ipv6        Match IPV6 header
  mark        Match on mark applied by firewall
  vif         Virtual Local Area Network (VLAN) ID for this match

```

As with other policies, you can *embed* other policies into the classes (and default) of your Priority Queue policy through the `queue-type` setting:

```

vyos@vyos# set traffic-policy priority-queue MY-PRIO class 3 queue-type
Possible completions:
  fq-codel      Fair Queue Codel
  fair-queue    Stochastic Fair Queue (SFQ)
  drop-tail     First-In-First-Out (FIFO)
  priority      Priority queueing based on DSCP
  random-detect Random Early Detection (RED)

```

set traffic-policy priority-queue <policy-name> class <class-ID> queue-limit <limit>

Use this command to configure a Priority Queue policy, set its name, set a class with a priority from 1 to 7 and define a hard limit on the real queue size. When this limit is reached, new packets are dropped.

Random-Detect

Queueing discipline: Generalized Random Early Drop.

Applies to: Outbound traffic.

A simple Random Early Detection (RED) policy would start randomly dropping packets from a queue before it reaches its queue limit thus avoiding congestion. That is good for TCP connections as the gradual dropping of packets acts as a signal for the sender to decrease its transmission rate.

In contrast to simple RED, VyOS' Random-Detect uses a Generalized Random Early Detect policy that provides different virtual queues based on the IP Precedence value so that some virtual queues can drop more packets than others.

This is achieved by using the first three bits of the ToS (Type of Service) field to categorize data streams and, in accordance with the defined precedence parameters, a decision is made.

IP precedence as defined in [RFC 791](#):

Precedence	Priority
7	Network Control
6	Internetwork Control
5	CRITIC/ECP
4	Flash Override
3	Flash
2	Immediate
1	Priority
0	Routine

Random-Detect could be useful for heavy traffic. One use of this algorithm might be to prevent a backbone overload. But only for TCP (because dropped packets could be retransmitted), not for UDP.

```
set traffic-policy random-detect <policy-name> bandwidth <bandwidth>
```

Use this command to configure a Random-Detect policy, set its name and set the available bandwidth for this policy. It is used for calculating the average queue size after some idle time. It should be set to the bandwidth of your interface. Random Detect is not a shaping policy, this command will not shape.

```
set traffic-policy random-detect <policy-name> precedence
<IP-precedence-value> average-packet <bytes>
```

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what the size of its average-packet should be (in bytes, default: 1024).

Note: When configuring a Random-Detect policy: **the higher the precedence number, the higher the priority.**

```
set traffic-policy random-detect <policy-name> precedence
<IP-precedence-value> mark-probability <value>
```

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its mark (drop) probability will be. Set the probability by giving the N value of the fraction 1/N (default: 10).

```
set traffic-policy random-detect <policy-name> precedence
<IP-precedence-value> maximum-threshold <packets>
```

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its maximum threshold for random detection will be (from 0 to 4096 packets, default: 18). At this size, the marking (drop) probability is maximal.

```
set traffic-policy random-detect <policy-name> precedence
<IP-precedence-value> minimum-threshold <packets>
```

Use this command to configure a Random-Detect policy and set its name, then state the IP Precedence for the virtual queue you are configuring and what its minimum threshold for random detection will be (from 0 to 4096 packets). If this value is exceeded, packets start being eligible for being dropped.

The default values for the minimum-threshold depend on IP precedence:

Precedence	default min-threshold
7	16
6	15
5	14
4	13
3	12
2	11
1	10
0	9

```
set traffic-policy random-detect <policy-name> precedence
<IP-precedence-value> queue-limit <packets>
```

Use this command to configure a Random-Detect policy and set its name, then name the IP Precedence for the virtual queue you are configuring and what the maximum size of its queue will be (from 1 to 1-4294967295 packets). Packets are dropped when the current queue length reaches this value.

If the average queue size is lower than the **min-threshold**, an arriving packet will be placed in the queue.

In the case the average queue size is between **min-threshold** and **max-threshold**, then an arriving packet would be either dropped or placed in the queue, it will depend on the defined **mark-probability**.

If the current queue size is larger than **queue-limit**, then packets will be dropped. The average queue size depends on its former average size and its current one.

If **max-threshold** is set but **min-threshold** is not, then ****min-threshold** is scaled to 50% of **max-threshold**.

In principle, values must be `min-threshold < max-threshold < queue-limit`.

Rate Control

Queueing discipline: Token Bucket Filter.

Applies to: Outbound traffic.

Rate-Control is a classless policy that limits the packet flow to a set rate. It is a pure shaper, it does not schedule traffic. Traffic is filtered based on the expenditure of tokens. Tokens roughly correspond to bytes.

Short bursts can be allowed to exceed the limit. On creation, the Rate-Control traffic is stocked with tokens which correspond to the amount of traffic that can be burst in one go. Tokens arrive at a steady rate, until the bucket is full.

```
set traffic-policy rate-control <policy-name> bandwidth <rate>
```

Use this command to configure a Rate-Control policy, set its name and the rate limit you want to have.

```
set traffic-policy rate-control <policy-name> burst <burst-size>
```

Use this command to configure a Rate-Control policy, set its name and the size of the bucket in bytes which will be available for burst.

As a reference: for 10mbit/s on Intel, you might need at least 10kbyte buffer if you want to reach your configured rate.

A very small buffer will soon start dropping packets.

```
set traffic-policy rate-control <policy-name> latency
```

Use this command to configure a Rate-Control policy, set its name and the maximum amount of time a packet can be queued (default: 50 ms).

Rate-Control is a CPU-friendly policy. You might consider using it when you just simply want to slow traffic down.

Round Robin

Queueing discipline: Deficit Round Robin.

Applies to: Outbound traffic.

The round-robin policy is a classful scheduler that divides traffic in different *classes* you can configure (up to 4096). You can *embed* a new policy into each of those classes (default included).

Each class is assigned a deficit counter (the number of bytes that a flow is allowed to transmit when it is its turn) initialized to quantum. Quantum is a parameter you configure which acts like a credit of fix bytes the counter receives on each round. Then the Round-Robin policy starts moving its Round Robin pointer through the queues. If the deficit counter is greater than the packet's size at the head of the queue, this packet will be sent and the value of the counter will be decremented by the packet size. Then, the size of the next packet will be compared to the counter value again, repeating the process. Once the queue is empty or the value of the counter is insufficient, the Round-Robin pointer will move to the next queue. If the queue is empty, the value of the deficit counter is reset to 0.

At every round, the deficit counter adds the quantum so that even large packets will have their opportunity to be dequeued.

```
set traffic-policy round-robin <policy name> class <class-ID> quantum  
<packets>
```

Use this command to configure a Round-Robin policy, set its name, set a class ID, and the quantum for that class. The deficit counter will add that value each round.

```
set traffic-policy round-robin <policy name> class <class ID> queue-limit  
<packets>
```

Use this command to configure a Round-Robin policy, set its name, set a class ID, and the queue size in packets.

As with other policies, Round-Robin can *embed* another policy into a class through the `queue-type` setting.

```
vyos@vyos# set traffic-policy round-robin DRR class 10 queue-type
Possible completions:
fq-codel      Fair Queue Codel
fair-queue    Stochastic Fair Queue (SFQ)
drop-tail     First-In-First-Out (FIFO)
priority      Priority queueing based on DSCP
```

Shaper

Queueing discipline: Hierarchical Token Bucket.

Applies to: Outbound traffic.

The Shaper policy does not guarantee a low delay, but it does guarantee bandwidth to different traffic classes and also lets you decide how to allocate more traffic once the guarantees are met.

Each class can have a guaranteed part of the total bandwidth defined for the whole policy, so all those shares together should not be higher than the policy's whole bandwidth.

If guaranteed traffic for a class is met and there is room for more traffic, the ceiling parameter can be used to set how much more bandwidth could be used. If guaranteed traffic is met and there are several classes willing to use their ceilings, the priority parameter will establish the order in which that additional traffic will be allocated. Priority can be any number from 0 to 7. The lower the number, the higher the priority.

```
set traffic-policy shaper <policy-name> bandwidth <rate>
```

Use this command to configure a Shaper policy, set its name and the maximum bandwidth for all combined traffic.

```
set traffic-policy shaper <policy-name> class <class-ID> bandwidth <rate>
```

Use this command to configure a Shaper policy, set its name, define a class and set the guaranteed traffic you want to allocate to that class.

```
set traffic-policy shaper <policy-name> class <class-ID> burst <bytes>
```

Use this command to configure a Shaper policy, set its name, define a class and set the size of the *token bucket* in bytes, which will be available to be sent at ceiling speed (default: 15Kb).

```
set traffic-policy shaper <policy-name> class <class-ID> ceiling <bandwidth>
```

Use this command to configure a Shaper policy, set its name, define a class and set the maximum speed possible for this class. The default ceiling value is the bandwidth value.

```
set traffic-policy shaper <policy-name> class <class-ID> priority <0-7>
```

Use this command to configure a Shaper policy, set its name, define a class and set the priority for usage of available bandwidth once guarantees have been met. The lower the priority number, the higher the priority. The default priority value is 0, the highest priority.

As with other policies, Shaper can *embed* other policies into its classes through the `queue-type` setting and then configure their parameters.

```
vyos@vyos# set traffic-policy shaper HTB class 10 queue-type
Possible completions:
fq-codel      Fair Queue Codel
fair-queue    Stochastic Fair Queue (SFQ)
drop-tail     First-In-First-Out (FIFO)
priority      Priority queueing based on DSCP
random-detect Random Early Detection (RED)
```

```
vyos@vyos# set traffic-policy shaper HTB class 10
Possible completions:
bandwidth     Bandwidth used for this class
burst         Burst size for this class (default: 15kb)
ceiling       Bandwidth limit for this class
codel-quantum fq-codel - Number of bytes used as 'deficit' (default 1514)
description   Description for this traffic class
flows         fq-codel - Number of flows (default 1024)
interval      fq-codel - Interval (milliseconds) used to measure the delay (default
→100)
+> match      Class matching rule name
priority      Priority for usage of excess bandwidth
queue-limit   Maximum queue size (packets)
queue-type    Queue type for this class
set-dscp      Change the Differentiated Services (DiffServ) field in the IP header
target        fq-codel - Acceptable minimum queue delay (milliseconds)
```

Note: If you configure a class for **VoIP traffic**, don't give it any *ceiling*, otherwise new VoIP calls could start when the link is available and get suddenly dropped when other classes start using their assigned *bandwidth* share.

Example

A simple example of Shaper using priorities.

```
set traffic-policy shaper MY-HTB bandwidth '50mbit'
set traffic-policy shaper MY-HTB class 10 bandwidth '20%'
set traffic-policy shaper MY-HTB class 10 match DSCP ip dscp 'EF'
set traffic-policy shaper MY-HTB class 10 queue-type 'fq-codel'
set traffic-policy shaper MY-HTB class 20 bandwidth '10%'
set traffic-policy shaper MY-HTB class 20 ceiling '50%'
set traffic-policy shaper MY-HTB class 20 match PORT666 ip destination port '666'
set traffic-policy shaper MY-HTB class 20 priority '3'
set traffic-policy shaper MY-HTB class 20 queue-type 'fair-queue'
set traffic-policy shaper MY-HTB class 30 bandwidth '10%'
set traffic-policy shaper MY-HTB class 30 ceiling '50%'
set traffic-policy shaper MY-HTB class 30 match ADDRESS30 ip source address '192.168.
→30.0/24'
```

(continues on next page)

(continued from previous page)

```
set traffic-policy shaper MY-HTB class 30 priority '5'
set traffic-policy shaper MY-HTB class 30 queue-type 'fair-queue'
set traffic-policy shaper MY-HTB default bandwidth '10%'
set traffic-policy shaper MY-HTB default ceiling '100%'
set traffic-policy shaper MY-HTB default priority '7'
set traffic-policy shaper MY-HTB default queue-type 'fair-queue'
```

Applying a traffic policy

Once a traffic-policy is created, you can apply it to an interface:

```
set interfaces ethernet eth0 traffic-policy out WAN-OUT
```

You can only apply one policy per interface and direction, but you could reuse a policy on different interfaces and directions:

```
set interfaces ethernet eth0 traffic-policy in WAN-IN
set interfaces ethernet eth0 traffic-policy out WAN-OUT
set interfaces ethernet eth1 traffic-policy in LAN-IN
set interfaces ethernet eth1 traffic-policy out LAN-OUT
set interfaces ethernet eth2 traffic-policy in LAN-IN
set interfaces ethernet eth2 traffic-policy out LAN-OUT
set interfaces ethernet eth3 traffic-policy in TWO-WAY-POLICY
set interfaces ethernet eth3 traffic-policy out TWO-WAY-POLICY
set interfaces ethernet eth4 traffic-policy in TWO-WAY-POLICY
set interfaces ethernet eth4 traffic-policy out TWO-WAY-POLICY
```

Getting queueing information

show queueing <interface-type> <interface-name>

Use this command to see the queueing information for an interface. You will be able to see a packet counter (Sent, Dropped, Overlimit and Backlog) per policy and class configured.

The case of ingress shaping

Applies to: Inbound traffic.

For the ingress traffic of an interface, there is only one policy you can directly apply, a **Limiter** policy. You cannot apply a shaping policy directly to the ingress traffic of any interface because shaping only works for outbound traffic.

This workaround lets you apply a shaping policy to the ingress traffic by first redirecting it to an in-between virtual interface ([Intermediate Functional Block](#)). There, in that virtual interface, you will be able to apply any of the policies that work for outbound traffic, for instance, a shaping one.

That is how it is possible to do the so-called “ingress shaping”.

```
set traffic-policy shaper MY-INGRESS-SHAPING bandwidth 1000kbit
set traffic-policy shaper MY-INGRESS-SHAPING default bandwidth 1000kbit
set traffic-policy shaper MY-INGRESS-SHAPING default queue-type fair-queue
```

(continues on next page)

(continued from previous page)

```
set interfaces input ifb0 traffic-policy out MY-INGRESS-SHAPING
set interfaces ethernet eth0 redirect ifb0
```

Warning: Do not configure IFB as the first step. First create everything else of your traffic-policy, and then you can configure IFB. Otherwise you might get the RTNETLINK answer: `File exists` error, which can be solved with `sudo ip link delete ifb0`.

8.13 VPN

8.13.1 IPsec

GRE (Generic Routing Encapsulation), GRE/IPsec (or IP/IPsec, SIT/IPsec, or any other stateless tunnel protocol over IPsec) is the usual way to protect the traffic inside a tunnel.

An advantage of this scheme is that you get a real interface with its own address, which makes it easier to setup static routes or use dynamic routing protocols without having to modify IPsec policies. The other advantage is that it greatly simplifies router to router communication, which can be tricky with plain IPsec because the external outgoing address of the router usually doesn't match the IPsec policy of typical site-to-site setup and you need to add special configuration for it, or adjust the source address for outgoing traffic of your applications. GRE/IPsec has no such problem and is completely transparent for the applications.

GRE/IPIP/SIT and IPsec are widely accepted standards, which make this scheme easy to implement between VyOS and virtually any other router.

For simplicity we'll assume that the protocol is GRE, it's not hard to guess what needs to be changed to make it work with a different protocol. We assume that IPsec will use pre-shared secret authentication and will use AES128/SHA1 for the cipher and hash. Adjust this as necessary.

Note: VMware users should ensure that a VMXNET3 adapter is used. E1000 adapters have known issues with GRE processing.

IPsec policy matching GRE

The first and arguably cleaner option is to make your IPsec policy match GRE packets between external addresses of your routers. This is the best option if both routers have static external addresses.

Suppose the LEFT router has external address 192.0.2.10 on its eth0 interface, and the RIGHT router is 203.0.113.45

On the LEFT:

```
# GRE tunnel
set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 local-ip 192.0.2.10
set interfaces tunnel tun0 remote-ip 203.0.113.45
set interfaces tunnel tun0 address 10.10.10.1/30

## IPsec
set vpn ipsec ipsec-interfaces interface eth0
```

(continues on next page)

(continued from previous page)

```
# IKE group
set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group '2'
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption 'aes128'
set vpn ipsec ike-group MyIKEGroup proposal 1 hash 'sha1'

# ESP group
set vpn ipsec esp-group MyESPGroup proposal 1 encryption 'aes128'
set vpn ipsec esp-group MyESPGroup proposal 1 hash 'sha1'

# IPsec tunnel
set vpn ipsec site-to-site peer 203.0.113.45 authentication mode pre-shared-secret
set vpn ipsec site-to-site peer 203.0.113.45 authentication pre-shared-secret MYSECRETKEY

set vpn ipsec site-to-site peer 203.0.113.45 ike-group MyIKEGroup
set vpn ipsec site-to-site peer 203.0.113.45 default-esp-group MyESPGroup

set vpn ipsec site-to-site peer 203.0.113.45 local-address 192.0.2.10

# This will match all GRE traffic to the peer
set vpn ipsec site-to-site peer 203.0.113.45 tunnel 1 protocol gre
```

On the RIGHT, setup by analogy and swap local and remote addresses.

Source tunnel from loopbacks

The scheme above doesn't work when one of the routers has a dynamic external address though. The classic workaround for this is to setup an address on a loopback interface and use it as a source address for the GRE tunnel, then setup an IPsec policy to match those loopback addresses.

We assume that the LEFT router has static 192.0.2.10 address on eth0, and the RIGHT router has a dynamic address on eth0.

Setting up the GRE tunnel

On the LEFT:

```
set interfaces loopback lo address 192.168.99.1/32

set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 address 10.10.10.1/30
set interfaces tunnel tun0 local-ip 192.168.99.1
set interfaces tunnel tun0 remote-ip 192.168.99.2
```

On the RIGHT:

```
set interfaces loopback lo address 192.168.99.2/32

set interfaces tunnel tun0 encapsulation gre
set interfaces tunnel tun0 address 10.10.10.2/30
set interfaces tunnel tun0 local-ip 192.168.99.2
set interfaces tunnel tun0 remote-ip 192.168.99.1
```

Setting up IPsec

However, now you need to make IPsec work with dynamic address on one side. The tricky part is that pre-shared secret authentication doesn't work with dynamic address, so we'll have to use RSA keys.

First, on both routers run the operational command “generate vpn rsa-key bits 2048”. You may choose different length than 2048 of course.

```
vyos@left# run generate vpn rsa-key bits 2048
Generating rsa-key to /config/ipsec.d/rsa-keys/localhost.key

Your new local RSA key has been generated
The public portion of the key is:

0sAQO2335[long string here]
```

Then on the opposite router, add the RSA key to your config.

```
set vpn rsa-keys rsa-key-name LEFT rsa-key KEYGOESHERE
```

Now you are ready to setup IPsec. You’ll need to use an ID instead of address for the peer on the dynamic side.

On the LEFT (static address):

```
set vpn rsa-keys rsa-key-name RIGHT rsa-key <PUBLIC KEY FROM THE RIGHT>

set vpn ipsec ipsec-interfaces interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer @RIGHT authentication mode rsa
set vpn ipsec site-to-site peer @RIGHT authentication rsa-key-name RIGHT
set vpn ipsec site-to-site peer @RIGHT default-esp-group MyESPGroup
set vpn ipsec site-to-site peer @RIGHT ike-group MyIKEGroup
set vpn ipsec site-to-site peer @RIGHT local-address 192.0.2.10
set vpn ipsec site-to-site peer @RIGHT connection-type respond
set vpn ipsec site-to-site peer @RIGHT tunnel 1 local prefix 192.168.99.1/32 #_
↪Additional loopback address on the local
set vpn ipsec site-to-site peer @RIGHT tunnel 1 remote prefix 192.168.99.2/32 #_
↪Additional loopback address on the remote
```

On the RIGHT (dynamic address):

```
set vpn rsa-keys rsa-key-name LEFT rsa-key <PUBLIC KEY FROM THE LEFT>

set vpn ipsec ipsec-interfaces interface eth0

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer 192.0.2.10 authentication id @RIGHT
set vpn ipsec site-to-site peer 192.0.2.10 authentication mode rsa
set vpn ipsec site-to-site peer 192.0.2.10 authentication rsa-key-name LEFT
set vpn ipsec site-to-site peer 192.0.2.10 authentication remote-id LEFT
```

(continues on next page)

(continued from previous page)

```

set vpn ipsec site-to-site peer 192.0.2.10 connection-type initiate
set vpn ipsec site-to-site peer 192.0.2.10 default-esp-group MyESPGroup
set vpn ipsec site-to-site peer 192.0.2.10 ike-group MyIKEGroup
set vpn ipsec site-to-site peer 192.0.2.10 local-address any
set vpn ipsec site-to-site peer 192.0.2.10 tunnel 1 local prefix 192.168.99.2/32 #_
↪Additional loopback address on the local
set vpn ipsec site-to-site peer 192.0.2.10 tunnel 1 remote prefix 192.168.99.1/32 #_
↪Additional loopback address on the remote

```

8.13.2 L2TP

VyOS utilizes `accel-ppp` to provide L2TP server functionality. It can be used with local authentication or a connected RADIUS server.

L2TP over IPsec

Example for configuring a simple L2TP over IPsec VPN for remote access (works with native Windows and Mac VPN clients):

```

set vpn ipsec ipsec-interfaces interface eth0

set vpn l2tp remote-access outside-address 192.0.2.2
set vpn l2tp remote-access client-ip-pool start 192.168.255.2
set vpn l2tp remote-access client-ip-pool stop 192.168.255.254
set vpn l2tp remote-access ipsec-settings authentication mode pre-shared-secret
set vpn l2tp remote-access ipsec-settings authentication pre-shared-secret <secret>
set vpn l2tp remote-access authentication mode local
set vpn l2tp remote-access authentication local-users username test password 'test'

```

In the example above an external IP of 192.0.2.2 is assumed.

If a local firewall policy is in place on your external interface you will need to allow the ports below:

- UDP port 500 (IKE)
- IP protocol number 50 (ESP)
- UDP port 1701 for IPsec

As well as the below to allow NAT-traversal (when NAT is detected by the VPN client, ESP is encapsulated in UDP for NAT-traversal):

- UDP port 4500 (NAT-T)

Example:

```

set firewall name OUTSIDE-LOCAL rule 40 action 'accept'
set firewall name OUTSIDE-LOCAL rule 40 protocol 'esp'
set firewall name OUTSIDE-LOCAL rule 41 action 'accept'
set firewall name OUTSIDE-LOCAL rule 41 destination port '500'
set firewall name OUTSIDE-LOCAL rule 41 protocol 'udp'
set firewall name OUTSIDE-LOCAL rule 42 action 'accept'
set firewall name OUTSIDE-LOCAL rule 42 destination port '4500'
set firewall name OUTSIDE-LOCAL rule 42 protocol 'udp'
set firewall name OUTSIDE-LOCAL rule 43 action 'accept'
set firewall name OUTSIDE-LOCAL rule 43 destination port '1701'

```

(continues on next page)

(continued from previous page)

```
set firewall name OUTSIDE-LOCAL rule 43 ipsec 'match-ipsec'
set firewall name OUTSIDE-LOCAL rule 43 protocol 'udp'
```

To allow VPN-clients access via your external address, a NAT rule is required:

```
set nat source rule 110 outbound-interface 'eth0'
set nat source rule 110 source address '192.168.255.0/24'
set nat source rule 110 translation address masquerade
```

VPN-clients will request configuration parameters, optionally you can DNS parameter to the client.

```
set vpn l2tp remote-access name-server '198.51.100.8'
set vpn l2tp remote-access name-server '198.51.100.4'
```

Established sessions can be viewed using the **show vpn remote-access** operational command, or **show l2tp-server sessions**

```
vyos@vyos:~$ show vpn remote-access
  ifname | username | calling-sid |      ip      | rate-limit | type | comp | state |
  ↪ | uptime
-----+-----+-----+-----+-----+-----+-----+-----
  ↪ +-----+
  ppp0   | vyos   | 192.168.0.36 | 192.168.255.1 |           | l2tp |      | active |
  ↪ | 00:06:13
```

LNS (L2TP Network Server)

LNS are often used to connect to a LAC (L2TP Access Concentrator).

Below is an example to configure a LNS:

```
set vpn l2tp remote-access outside-address 192.0.2.2
set vpn l2tp remote-access client-ip-pool start 192.168.255.2
set vpn l2tp remote-access client-ip-pool stop 192.168.255.254
set vpn l2tp remote-access lns shared-secret 'secret'
set vpn l2tp remote-access ccp-disable
set vpn l2tp remote-access authentication mode local
set vpn l2tp remote-access authentication local-users username test password 'test'
```

The example above uses 192.0.2.2 as external IP address. A LAC normally requires an authentication password, which is set in the example configuration to `lns shared-secret 'secret'`. This setup requires the Compression Control Protocol (CCP) being disabled, the command `set vpn l2tp remote-access ccp-disable` accomplishes that.

Bandwidth Shaping

Bandwidth rate limits can be set for local users or via RADIUS based attributes.

Bandwidth Shaping for local users

The rate-limit is set in kbit/sec.

```

set vpn l2tp remote-access outside-address 192.0.2.2
set vpn l2tp remote-access client-ip-pool start 192.168.255.2
set vpn l2tp remote-access client-ip-pool stop 192.168.255.254
set vpn l2tp remote-access authentication mode local
set vpn l2tp remote-access authentication local-users username test password test
set vpn l2tp remote-access authentication local-users username test rate-limit
↪download 20480
set vpn l2tp remote-access authentication local-users username test rate-limit upload
↪10240

vyos@vyos:~$ show vpn remote-access
ifname | username | calling-sid | ip | rate-limit | type | comp | state
↪| uptime
-----+-----+-----+-----+-----+-----+-----+-----
↪+-----+
ppp0 | test | 192.168.0.36 | 192.168.255.2 | 20480/10240 | l2tp | | active
↪| 00:06:30

```

RADIUS authentication

To enable RADIUS based authentication, the authentication mode needs to be changed within the configuration. Previous settings like the local users, still exists within the configuration, however they are not used if the mode has been changed from local to radius. Once changed back to local, it will use all local accounts again.

```
set vpn l2tp remote-access authentication mode <local|radius>
```

Since the RADIUS server would be a single point of failure, multiple RADIUS servers can be setup and will be used subsequently.

```

set vpn l2tp remote-access authentication radius server 10.0.0.1 key 'foo'
set vpn l2tp remote-access authentication radius server 10.0.0.2 key 'foo'

```

Note: Some RADIUS servers use an access control list which allows or denies queries, make sure to add your VyOS router to the allowed client list.

RADIUS source address

If you are using OSPF as IGP, always the closest interface connected to the RADIUS server is used. With VyOS 1.2 you can bind all outgoing RADIUS requests to a single source IP e.g. the loopback interface.

```
set vpn l2tp remote-access authentication radius source-address 10.0.0.3
```

Above command will use *10.0.0.3* as source IPv4 address for all RADIUS queries on this NAS.

Note: The `source-address` must be configured on one of VyOS interface. Best practice would be a loopback or dummy interface.

RADIUS bandwidth shaping attribute

To enable bandwidth shaping via RADIUS, the option `rate-limit` needs to be enabled.

```
set vpn l2tp remote-access authentication radius rate-limit enable
```

The default RADIUS attribute for rate limiting is `Filter-Id`, but you may also redefine it.

```
set vpn l2tp remote-access authentication radius rate-limit attribute Download-Speed
```

Note: If you set a custom RADIUS attribute you must define it on both dictionaries at RADIUS server and client, which is the vyos router in our example.

The RADIUS dictionaries in VyOS are located at `/usr/share/accel-ppp/radius/`

RADIUS advanced features

Received RADIUS attributes have a higher priority than parameters defined within the CLI configuration, refer to the explanation below.

Allocation clients ip addresses by RADIUS

If the RADIUS server sends the attribute `Framed-IP-Address` then this IP address will be allocated to the client and the option `ip-pool` within the CLI config is being ignored.

Renaming clients interfaces by RADIUS

If the RADIUS server uses the attribute `NAS-Port-Id`, ppp tunnels will be renamed.

Note: The value of the attribute `NAS-Port-Id` must be less than 16 characters, otherwise the interface won't be renamed.

8.13.3 OpenConnect

OpenConnect-compatible server feature is available from this release. Openconnect VPN supports SSL connection and offers full network access. SSL VPN network extension connects the end-user system to the corporate network with access controls based only on network layer information, such as destination IP address and port number. So, it provides safe communication for all types of device traffic across public networks and private networks, also encrypts the traffic with SSL protocol.

The remote user will use the openconnect client to connect to the router and will receive an IP address from a VPN pool, allowing full access to the network.

Note: All certificates should be stored on VyOS under `/config/auth`. If certificates are not stored in the `/config` directory they will not be migrated during a software update.

Configuration

SSL Certificates

We need to generate the certificate which authenticates users who attempt to access the network resource through the SSL VPN tunnels. The following command will create a self signed certificates and will be stored in the file path `/config/auth`.

```
openssl req -newkey rsa:4096 -new -nodes -x509 -days 3650 -keyout /config/auth/server.  
↪key -out /config/auth/server.crt  
openssl req -new -x509 -key /config/auth/server.key -out /config/auth/ca.crt
```

We can also create the certificates using Certbot which is an easy-to-use client that fetches a certificate from Let's Encrypt an open certificate authority launched by the EFF, Mozilla, and others and deploys it to a web server.

```
sudo certbot certonly --standalone --preferred-challenges http -d <domain name>
```

Server Configuration

```
set vpn openconnect authentication local-users username <user> password <pass>  
set vpn openconnect authentication mode <local|radius>  
set vpn openconnect network-settings client-ip-settings subnet <subnet>  
set vpn openconnect network-settings name-server <address>  
set vpn openconnect network-settings name-server <address>  
set vpn openconnect ssl ca-cert-file <file>  
set vpn openconnect ssl cert-file <file>  
set vpn openconnect ssl key-file <file>
```

Example

Use local user name “user4” with password “SecretPassword” Client IP addresses will be provided from pool 100.64.0.0/24 The Gateway IP Address must be in one of the router’s interfaces.

```
set vpn openconnect authentication local-users username user4 password 'SecretPassword  
↪'  
set vpn openconnect authentication mode 'local'  
set vpn openconnect network-settings client-ip-settings subnet '100.64.0.0/24'  
set vpn openconnect network-settings name-server '10.1.1.1'  
set vpn openconnect network-settings name-server '10.1.1.2'  
set vpn openconnect ssl ca-cert-file '/config/auth/fullchain.pem'  
set vpn openconnect ssl cert-file '/config/auth/cert.pem'  
set vpn openconnect ssl key-file '/config/auth/privkey.pem'
```

Verification

```
vyos@RTR1:~$ show openconnect-server sessions
```

interface	username	ip	remote IP	RX	TX	state
↪uptime						

↪-----						
sslvpn0	user4	100.64.0.105	xx.xxx.49.253	127.3 KB	160.0 KB	connected

↪12m:28s (continues on next page)

(continued from previous page)

Note: It is compatible with Cisco (R) AnyConnect (R) clients.

8.13.4 PPTP-Server

The Point-to-Point Tunneling Protocol (*PPTP*) has been implemented in VyOS only for backwards compatibility. PPTP has many well known security issues and you should use one of the many other new VPN implementations.

As per default and if not otherwise defined, mschap-v2 is being used for authentication and mppe 128-bit (stateless) for encryption. If no gateway-address is set within the configuration, the lowest IP out of the /24 client-ip-pool is being used. For instance, in the example below it would be 192.168.0.1.

server example

```
set vpn pptp remote-access authentication local-users username test password 'test'
set vpn pptp remote-access authentication mode 'local'
set vpn pptp remote-access client-ip-pool start '192.168.0.10'
set vpn pptp remote-access client-ip-pool stop '192.168.0.15'
set vpn pptp remote-access gateway-address '10.100.100.1'
set vpn pptp remote-access outside-address '10.1.1.120'
```

client example (debian 9)

Install the client software via apt and execute pptpsetup to generate the configuration.

```
apt-get install pptp-linux
pptpsetup --create TESTTUNNEL --server 10.1.1.120 --username test --password test --
->encrypt
pon TESTTUNNEL
```

The command pon TESTTUNNEL establishes the PPTP tunnel to the remote system.

All tunnel sessions can be checked via:

```
run sh pptp-server sessions
ifname | username | calling-sid | ip | type | comp | state | uptime
-----+-----+-----+-----+-----+-----+-----+-----
ppp0 | test | 10.1.1.99 | 192.168.0.10 | pptp | mppe | active | 00:00:58
```

8.13.5 RSA-Keys

RSA can be used for services such as key exchanges and for encryption purposes. To make IPSec work with dynamic address on one/both sides, we will have to use RSA keys for authentication. They are very fast and easy to setup.

First, on both routers run the operational command “generate vpn rsa-key bits 2048”. You may choose different length than 2048 of course.

```
vyos@left# run generate vpn rsa-key bits 2048
Generating rsa-key to /config/ipsec.d/rsa-keys/localhost.key
```

Your new local RSA key has been generated
The public portion of the key is:

```
0sAQO2335[long string here]
```

Please note down this public key, as you have to add this RSA key in the opposite router.

```
set vpn rsa-keys rsa-key-name LEFT rsa-key KEYGOESHERE
```

Now you are ready to setup IPsec. The key points:

1. Since both routers do not know their effective public addresses, we set the local-address of the peer to “any”.
2. On the initiator, we set the peer address to its public address, but on the responder we only set the id.
3. On the initiator, we need to set the remote-id option so that it can identify IKE traffic from the responder correctly.
4. On the responder, we need to set the local id so that initiator can know who’s talking to it for the point #3 to work.
5. Don’t forget to enable NAT traversal on both sides, “set vpn ipsec nat-traversal enable”.

LEFT SIDE:

```
set vpn rsa-keys rsa-key-name RIGHT rsa-key <PUBLIC KEY FROM THE RIGHT>

set vpn ipsec ipsec-interfaces interface eth0
set vpn ipsec nat-traversal 'enable'

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer 192.0.2.60 authentication mode rsa
set vpn ipsec site-to-site peer 192.0.2.60 authentication id @LEFT
set vpn ipsec site-to-site peer 192.0.2.60 authentication rsa-key-name RIGHT
set vpn ipsec site-to-site peer 192.0.2.60 authentication remote-id RIGHT
set vpn ipsec site-to-site peer 192.0.2.60 default-esp-group MyESPGroup
set vpn ipsec site-to-site peer 192.0.2.60 ike-group MyIKEGroup
set vpn ipsec site-to-site peer 192.0.2.60 local-address any
set vpn ipsec site-to-site peer 192.0.2.60 connection-type initiate
set vpn ipsec site-to-site peer 192.0.2.60 tunnel 1 local prefix 192.168.99.1/32
set vpn ipsec site-to-site peer 192.0.2.60 tunnel 1 remote prefix 192.168.99.2/32
```

RIGHT SIDE:

```
set vpn rsa-keys rsa-key-name LEFT rsa-key <PUBLIC KEY FROM THE LEFT>

set vpn ipsec ipsec-interfaces interface eth0
set vpn ipsec nat-traversal 'enable'

set vpn ipsec esp-group MyESPGroup proposal 1 encryption aes128
```

(continues on next page)

(continued from previous page)

```
set vpn ipsec esp-group MyESPGroup proposal 1 hash sha1

set vpn ipsec ike-group MyIKEGroup proposal 1 dh-group 2
set vpn ipsec ike-group MyIKEGroup proposal 1 encryption aes128
set vpn ipsec ike-group MyIKEGroup proposal 1 hash sha1

set vpn ipsec site-to-site peer @LEFT authentication id @RIGHT
set vpn ipsec site-to-site peer @LEFT authentication mode rsa
set vpn ipsec site-to-site peer @LEFT authentication rsa-key-name LEFT
set vpn ipsec site-to-site peer @LEFT connection-type respond
set vpn ipsec site-to-site peer @LEFT default-esp-group MyESPGroup
set vpn ipsec site-to-site peer @LEFT ike-group MyIKEGroup
set vpn ipsec site-to-site peer @LEFT local-address any
set vpn ipsec site-to-site peer @LEFT tunnel 1 local prefix 192.168.99.2/32
set vpn ipsec site-to-site peer @LEFT tunnel 1 remote prefix 192.168.99.1/32
```

8.13.6 SSTP

SSTP (Secure Socket Tunneling Protocol) is a form of VPN (Virtual Private Network) tunnel that provides a mechanism to transport PPP traffic through an SSL/TLS channel. SSL/TLS provides transport-level security with key negotiation, encryption and traffic integrity checking. The use of SSL/TLS over TCP port 443 allows SSTP to pass through virtually all firewalls and proxy servers except for authenticated web proxies.

SSTP is available for Linux, BSD, and Windows.

VyOS utilizes [accel-ppp](#) to provide SSTP server functionality. We support both local and RADIUS authentication.

As SSTP provides PPP via a SSL/TLS channel the use of either publically signed certificates as well as a private PKI is required.

Note: All certificates should be stored on VyOS under `/config/auth`. If certificates are not stored in the `config` directory they will not be migrated during a software update.

Certificates

Self Signed CA

To generate the CA, the server private key and certificates the following commands can be used.

```
vyos@vyos:~$ mkdir -p /config/user-data/sstp
vyos@vyos:~$ openssl req -newkey rsa:4096 -new -nodes -x509 -days 3650 -keyout /
->config/user-data/sstp/server.key -out /config/user-data/sstp/server.crt
```

```
Generating a 4096 bit RSA private key
.....++
.....++
writing new private key to 'server.key'

Configuration

set vpn sstp authentication local-users username <user> password <pass>

Create <user> for local authentication on this system. The users password will be set to <pass>.

set vpn sstp authentication local-users username <user> disable

Disable <user> account.

set vpn sstp authentication local-users username <user> static-ip <address>

Assign static IP address to <user> account.

set vpn sstp authentication local-users username <user> rate-limit download <bandwidth>

Download bandwidth limit in kbit/s for <user>.

set vpn sstp authentication local-users username <user> rate-limit upload <bandwidth>

Upload bandwidth limit in kbit/s for <user>.

set vpn sstp authentication protocols <pap | chap | mschap | mschap-v2>

Require the peer to authenticate itself using one of the following protocols: pap, chap, mschap, mschap-v2.

set vpn sstp authentication mode <local | radius>

Set authentication backend. The configured authentication backend is used for all queries.

- **radius:** All authentication queries are handled by a configured RADIUS server.
- **local:** All authentication queries are handled locally.

set vpn sstp gateway-address <gateway>

Specifies single <gateway> IP address to be used as local address of PPP interfaces.

set vpn sstp client-ip-pool subnet <subnet>

Use <subnet> as the IP pool for all connecting clients.

set vpn sstp client-ipv6-pool prefix <address> mask <number-of-bits>

Use this command to set the IPv6 address pool from which an SSTP client will get an IPv6 prefix of your defined length (mask) to terminate the SSTP endpoint at their side. The mask length can be set from 48 to 128 bit long, the default value is 64.

```
set vpn sstp client-ipv6-pool delegate <address> delegation-prefix  
<number-of-bits>
```

Use this command to configure DHCPv6 Prefix Delegation (RFC3633) on SSTP. You will have to set your IPv6 pool and the length of the delegation prefix. From the defined IPv6 pool you will be handing out networks of the defined length (delegation-prefix). The length of the delegation prefix can be set from 32 to 64 bit long.

```
set vpn sstp name-server <address>
```

Connected client should use *<address>* as their DNS server. This command accepts both IPv4 and IPv6 addresses. Up to two nameservers can be configured for IPv4, up to three for IPv6.

Maximum number of IPv4 nameservers

SSL Certificates

```
set vpn sstp ssl ca-cert-file <file>
```

Path to *<file>* pointing to the certificate authority certificate.

```
set vpn sstp ssl cert-file <file>
```

Path to *<file>* pointing to the servers certificate (public portion).

```
set vpn sstp ssl key-file <file>
```

Path to *<file>* pointing to the servers certificate (private portion).

PPP Settings

```
set vpn sstp ppp-options lcp-echo-failure <number>
```

Defines the maximum *<number>* of unanswered echo requests. Upon reaching the value *<number>*, the session will be reset.

```
set vpn sstp ppp-options lcp-echo-interval <interval>
```

If this option is specified and is greater than 0, then the PPP module will send LCP pings of the echo request every *<interval>* seconds.

```
set vpn sstp ppp-options lcp-echo-timeout
```

Specifies timeout in seconds to wait for any peer activity. If this option specified it turns on adaptive lcp echo functionality and “lcp-echo-failure” is not used.

```
set vpn sstp ppp-options mppe <require | prefer | deny>
```

Specifies MPPE (Microsoft Point-to-Point Encryption) negotiation preference.

- **require** - ask client for mppe, if it rejects drop connection
- **prefer** - ask client for mppe, if it rejects don't fail
- **deny** - deny mppe

Default behavior - don't ask client for mppe, but allow it if client wants. Please note that RADIUS may override this option by MS-MPPE-Encryption-Policy attribute.

RADIUS

Server

```
set vpn sstp authentication radius server <server> port <port>
```

Configure RADIUS <server> and its required port for authentication requests.

```
set vpn sstp authentication radius server <server> key <secret>
```

Configure RADIUS <server> and its required shared <secret> for communicating with the RADIUS server.

```
set vpn sstp authentication radius server <server> fail-time <time>
```

Mark RADIUS server as offline for this given <time> in seconds.

```
set vpn sstp authentication radius server <server> disable
```

Temporary disable this RADIUS server.

Options

```
set vpn sstp authentication radius acct-timeout <timeout>
```

Timeout to wait reply for Interim-Update packets. (default 3 seconds)

```
set vpn sstp authentication radius dynamic-author server <address>
```

Specifies IP address for Dynamic Authorization Extension server (DM/CoA)

```
set vpn sstp authentication radius dynamic-author port <port>
```

Port for Dynamic Authorization Extension server (DM/CoA)

```
set vpn sstp authentication radius dynamic-author key <secret>
```

Secret for Dynamic Authorization Extension server (DM/CoA)

```
set vpn sstp authentication radius max-try <number>
```

Maximum number of tries to send Access-Request/Accounting-Request queries

```
set vpn sstp authentication radius timeout <timeout>
```

Timeout to wait response from server (seconds)

```
set vpn sstp authentication radius nas-identifier <identifier>
```

Value to send to RADIUS server in NAS-Identifier attribute and to be matched in DM/CoA requests.

```
set vpn sstp authentication radius nas-ip-address <address>
```

Value to send to RADIUS server in NAS-IP-Address attribute and to be matched in DM/CoA requests. Also DM/CoA server will bind to that address.

```
set vpn sstp authentication radius source-address <address>
```

Source IPv4 address used in all RADIUS server queries.

```
set vpn sstp authentication radius rate-limit attribute <attribute>
```

Specifies which RADIUS server attribute contains the rate limit information. The default attribute is *Filter-Id*.

```
set vpn sstp authentication radius rate-limit enable
```

Enables bandwidth shaping via RADIUS.

set vpn sstp authentication radius rate-limit vendor

Specifies the vendor dictionary, dictionary needs to be in /usr/share/accel-ppp/radius.

Example

- Use local user *foo* with password *bar*
- Client IP addresses will be provided from pool *192.0.2.0/25*

```
set vpn sstp authentication local-users username vyos password vyos
set vpn sstp authentication mode local
set vpn sstp gateway-address 192.0.2.254
set vpn sstp client-ip-pool subnet 192.0.2.0/25
set vpn sstp name-server 10.0.0.1
set vpn sstp name-server 10.0.0.2
set vpn sstp ssl ca-cert-file /config/auth/ca.crt
set vpn sstp ssl cert-file /config/auth/server.crt
set vpn sstp ssl key-file /config/auth/server.key
```

Testing SSTP

Once you have setup your SSTP server there comes the time to do some basic testing. The Linux client used for testing is called **sstpc**. **sstpc** requires a PPP configuration/peer file.

The following PPP configuration tests MSCHAP-v2:

```
$ cat /etc/ppp/peers/vyos
usepeerdns
#require-mppe
#require-pap
require-mschap-v2
noauth
lock
refuse-pap
refuse-eap
refuse-chap
refuse-mschap
#refuse-mschap-v2
nobsdcomp
nodeflate
debug
```

You can now “dial” the peer with the following command: **sstpc --log-level 4 --log-stderr --user vyos --password vyos vpn.example.com -- call vyos**.

A connection attempt will be shown as:

```
$ sstpc --log-level 4 --log-stderr --user vyos --password vyos vpn.example.com --
↪call vyos

8.13.7 DMVPN

DMVPN (Dynamic Multipoint Virtual Private Network) is a dynamic VPN technology originally developed by Cisco. While their implementation was somewhat proprietary, the underlying technologies are actually standards based. The three technologies are:

- NHRP (Next Hop Resolution Protocol) [RFC 2332](#)
- MGRE (Multipoint Generic Routing Encapsulation) [RFC 1702](#)
- IPSEC (IP Security) - too many RFCs to list, but start with [RFC 4301](#)

NHRP provides the dynamic tunnel endpoint discovery mechanism (endpoint registration, and endpoint discovery/lookup), mGRE provides the tunnel encapsulation itself, and the IPSec protocols handle the key exchange, and crypto mechanism.

In short, DMVPN provides the capability for creating a dynamic-mesh VPN network without having to pre-configure (static) all possible tunnel end-point peers.

Note: DMVPN only automates the tunnel endpoint discovery and setup. A complete solution also incorporates the use of a routing protocol. BGP is particularly well suited for use with DMVPN.

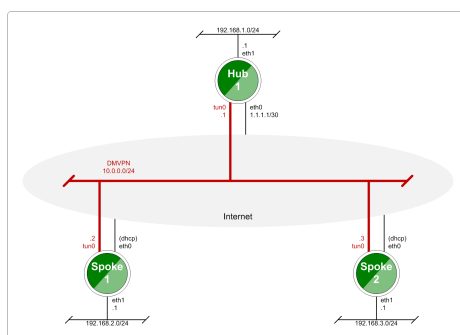

Fig. 6: Baseline DMVPN topology

Configuration

- Please refer to the [Tunnel](#) documentation for the individual tunnel related options.
- Please refer to the [IPsec](#) documentation for the individual IPsec related options.

set protocols nhrp tunnel <tunnel> cisco-authentication <secret>

Enables Cisco style authentication on NHRP packets. This embeds the secret plaintext password to the outgoing NHRP packets. Incoming NHRP packets on this interface are discarded unless the secret password is present. Maximum length of the secret is 8 characters.

set protocols nhrp tunnel <tunnel> dynamic-map <address> nbma-domain-name <fqdn>

Specifies that the NBMA (Non-broadcast multiple-access network) addresses of the next hop servers are defined in the domain name nbma-domain-name. For each A record opennhrp creates a dynamic NHS entry.

Each dynamic NHS will get a peer entry with the configured network address and the discovered NBMA address.

The first registration request is sent to the protocol broadcast address, and the server's real protocol address is dynamically detected from the first registration reply.

set protocols nhrp tunnel <tunnel> holding-time <timeout>

Specifies the holding time for NHRP Registration Requests and Resolution Replies sent from this interface or shortcut-target. The holdtime is specified in seconds and defaults to two hours.

set protocols nhrp tunnel <tunnel> map cisco

If the statically mapped peer is running Cisco IOS, specify the cisco keyword. It is used to fix statically the Registration Request ID so that a matching Purge Request can be sent if NBMA address has changed. This is to work around broken IOS which requires Purge Request ID to match the original Registration Request ID.

set protocols nhrp tunnel <tunnel> map nbma-address <address>

Creates static peer mapping of protocol-address to NBMA address.

If the IP prefix mask is present, it directs opennhrp to use this peer as a next hop server when sending Resolution Requests matching this subnet.

This is also known as the HUBs IP address or FQDN.

set protocols nhrp tunnel <tunnel> map register

The optional parameter register specifies that Registration Request should be sent to this peer on startup.

This option is required when running a DMVPN spoke.

set protocols nhrp tunnel <tunnel> multicast <dynamic | nhs>

Determines how opennhrp daemon should soft switch the multicast traffic. Currently, multicast traffic is captured by opennhrp daemon using a packet socket, and resent back to proper destinations. This means that multicast packet sending is CPU intensive.

Specyfing nhs makes all multicast packets to be repeated to each statically configured next hop.

Synamic instructs to forward to all peers which we have a direct connection with. Alternatively, you can specify the directive multiple times for each protocol-address the multicast traffic should be sent to.

Warning: It is very easy to misconfigure multicast repeating if you have multiple NHSes.

set protocols nhrp tunnel <tunnel> non-caching

Disables caching of peer information from forwarded NHRP Resolution Reply packets. This can be used to reduce memory consumption on big NBMA subnets.

Note: Currently does not do much as caching is not implemented.

set protocols nhrp tunnel <tunnel> redirect

Enable sending of Cisco style NHRP Traffic Indication packets. If this is enabled and opennhrp detects a forwarded packet, it will send a message to the original sender of the packet instructing it to create a direct connection with the destination. This is basically a protocol independent equivalent of ICMP redirect.

set protocols nhrp tunnel <tunnel> shortcut

Enable creation of shortcut routes.

A received NHRP Traffic Indication will trigger the resolution and establishment of a shortcut route.

set protocols nhrp tunnel <tunnel> shortcut-destination

This instructs opennhrp to reply with authoritative answers on NHRP Resolution Requests destined to addresses in this interface (instead of forwarding the packets). This effectively allows the creation of shortcut routes to subnets located on the interface.

When specified, this should be the only keyword for the interface.

set protocols nhrp tunnel <tunnel> shortcut-target <address>

Defines an off-NBMA network prefix for which the GRE interface will act as a gateway. This an alternative to defining local interfaces with shortcut-destination flag.

set protocols nhrp tunnel <tunnel> shortcut-target <address> holding-time <timeout>

Specifies the holding time for NHRP Registration Requests and Resolution Replies sent from this interface or shortcut-target. The holdtime is specified in seconds and defaults to two hours.

Example

This blueprint uses VyOS as the DMVPN Hub and Cisco (7206VXR) and VyOS as multiple spoke sites. The lab was build using EVE-NG (Emulated Virtual Environment NG).

Each node (Hub and Spoke) uses an IP address from the network 172.16.253.128/29.

The below referenced IP address *192.0.2.1* is used as example address representing a global unicast address under which the HUB can be contacted by each and every individual spoke.

Configuration

Hub

```
set interfaces ethernet eth0 address 192.0.2.1/24

set interfaces tunnel tun100 address '172.16.253.134/29'
set interfaces tunnel tun100 encapsulation 'gre'
set interfaces tunnel tun100 local-ip '192.0.2.1'
set interfaces tunnel tun100 multicast 'enable'
set interfaces tunnel tun100 parameters ip key '1'
```

(continues on next page)

Fig. 7: DMVPN example network

(continued from previous page)

```

set vpn ipsec ike-group IKE-HUB proposal 2 encryption 'aes128'
set vpn ipsec ike-group IKE-HUB proposal 2 hash 'sha1'

set vpn ipsec ipsec-interfaces interface 'eth0'

set vpn ipsec profile NHRPVPN authentication mode 'pre-shared-secret'
set vpn ipsec profile NHRPVPN authentication pre-shared-secret 'secret'

```

(continues on next page)

(continued from previous page)

```
set vpn ipsec profile NHRPVPN bind tunnel 'tun100'
set vpn ipsec profile NHRPVPN esp-group 'ESP-HUB'
set vpn ipsec profile NHRPVPN ike-group 'IKE-HUB'
```

Note: Setting this up on AWS will require a “Custom Protocol Rule” for protocol number “47” (GRE) Allow Rule in TWO places. Firstly on the VPC Network ACL, and secondly on the security group network ACL attached to the EC2 instance. This has been tested as working for the official AMI image on the AWS Marketplace. (Locate the correct VPC and security group by navigating through the details pane below your EC2 instance in the AWS console).

Spoke

The individual spoke configurations only differ in the local IP address on the `tun10` interface. See the above diagram for the individual IP addresses.

spoke01-spoke04

```

8.13.8 Site-to-Site

Site-to-site mode provides a way to add remote peers, which could be configured to exchange encrypted information between them and VyOS itself or connected/routed networks.

To configure site-to-site connection you need to add peers with the `set vpn ipsec site-to-site` command.

You can identify a remote peer with:

- IPv4 or IPv6 address. This mode is easiest for configuration and mostly used when a peer has a public static IP address;
- Hostname. This mode is similar to IP address, only you define DNS name instead of an IP. Could be used when a peer has a public IP address and DNS name, but an IP address could be changed from time to time;
- Remote ID of the peer. In this mode, there is no predefined remote address nor DNS name of the peer. This mode is useful when a peer doesn't have a publicly available IP address (NAT between it and VyOS), or IP address could be changed.

Each site-to-site peer has the next options:

- `authentication` - configure authentication between VyOS and a remote peer. Suboptions:
 - `id` - ID for the local VyOS router. If defined, during the authentication it will be send to remote peer;
 - `mode` - mode for authentication between VyOS and remote peer:
 - `pre-shared-secret` - use predefined shared secret phrase, must be the same for local and remote side;
 - `rsa` - use simple shared RSA key. The key must be defined in the `set vpn rsa-keys` section;
 - `x509` - use certificates infrastructure for authentication.
 - `pre-shared-secret` - predefined shared secret. Used if configured mode `pre-shared-secret`;
 - `remote-id` - define an ID for remote peer, instead of using peer name or address. Useful in case if the remote peer is behind NAT or if mode `x509` is used;
 - `rsa-key-name` - shared RSA key for authentication. The key must be defined in the `set vpn rsa-keys` section;
 - `use-x509-id` - use local ID from x509 certificate. Cannot be used when `id` is defined;
 - `x509` - options for x509 authentication mode:
 - `ca-cert-file` - CA certificate file. Using for authenticating remote peer;
 - `cert-file` - certificate file, which will be used for authenticating local router on remote peer;
 - `crl-file` - file with the Certificate Revocation List. Using to check if a certificate for the remote peer is valid or revoked;
 - `key` - a private key, which will be used for authenticating local router on remote peer;
 - `file` - path to the key file;
 - `password` - passphrase private key, if needed.
- `connection-type` - how to handle this connection process. Possible variants:

- `initiate` - do initial connection to remote peer immediately after configuring and after boot. In this mode the connection will not be restarted in case of disconnection, therefore should be used only together with DPD or another session tracking methods;
- `respond` - do not try to initiate a connection to a remote peer. In this mode, the IPsec session will be established only after initiation from a remote peer. Could be useful when there is no direct connectivity to the peer due to firewall or NAT in the middle of the local and remote side.
- `default-esp-group` - ESP group to use by default for traffic encryption. Might be overwritten by individual settings for tunnel or VTI interface binding;
- `description` - description for this peer;
- `dhcp-interface` - use an IP address, received from DHCP for IPsec connection with this peer, instead of `local-address`;
- `force-encapsulation` - force encapsulation of ESP into UDP datagrams. Useful in case if between local and remote side is firewall or NAT, which not allows passing plain ESP packets between them;
- `ike-group` - IKE group to use for key exchanges;
- `ikev2-reauth` - reauthenticate remote peer during the rekeying process. Can be used only with IKEv2;
- `yes` - create a new `IKE_SA` from the scratch and try to recreate all IPsec SAs;
- `no` - rekey without uninstalling the IPsec SAs;
- `inherit` - use default behavior for the used IKE group.
- `local-address` - local IP address for IPsec connection with this peer. If defined any, then an IP address which configured on interface with default route will be used;
- `tunnel` - define criteria for traffic to be matched for encrypting and send it to a peer:
 - `disable` - disable this tunnel;
 - `esp-group` - define ESP group for encrypt traffic, defined by this tunnel;
 - `local` - define a local source for match traffic, which should be encrypted and send to this peer:
 - `port` - define port. Have effect only when used together with `prefix`;
 - `prefix` - IP network at local side.
 - `protocol` - define the protocol for match traffic, which should be encrypted and send to this peer;
 - `remote` - define the remote destination for match traffic, which should be encrypted and send to this peer:
 - `port` - define port. Have effect only when used together with `prefix`;
 - `prefix` - IP network at remote side.
- `vti` - use a VTI interface for traffic encryption. Any traffic, which will be send to VTI interface will be encrypted and send to this peer. Using VTI makes IPsec configuration much flexible and easier in complex situation, and allows to dynamically add/delete remote networks, reachable via a peer, as in this mode router don't need to create additional SA/policy for each remote network:
- `bind` - select a VTI interface to bind to this peer;
- `esp-group` - define ESP group for encrypt traffic, passed this VTI interface.

Examples:**IKEv1****Example:**

- WAN interface on *eth1*
- left subnet: *192.168.0.0/24* site1, server side (i.e. locality, actually there is no client or server roles)
- left local_ip: *198.51.100.3* # server side WAN IP
- right subnet: *10.0.0.0/24* site2, remote office side
- right local_ip: *203.0.113.2* # remote office side WAN IP

```

```

If there is SNAT rules on eth1, need to add exclude rule

```

# server side
set nat source rule 10 destination address '10.0.0.0/24'
set nat source rule 10 'exclude'
set nat source rule 10 outbound-interface 'eth1'
set nat source rule 10 source address '192.168.0.0/24'

# remote office side
set nat source rule 10 destination address '192.168.0.0/24'
set nat source rule 10 'exclude'
set nat source rule 10 outbound-interface 'eth1'
set nat source rule 10 source address '10.0.0.0/24'

```

To allow traffic to pass through to clients, you need to add the following rules. (if you used the default configuration at the top of this page)

```

# server side
set firewall name OUTSIDE-LOCAL rule 32 action 'accept'
set firewall name OUTSIDE-LOCAL rule 32 source address '10.0.0.0/24'

# remote office side
set firewall name OUTSIDE-LOCAL rule 32 action 'accept'
set firewall name OUTSIDE-LOCAL rule 32 source address '192.168.0.0/24'

```

IKEv2

Example:

- left local_ip: 192.168.0.10 # VPN Gateway, behind NAT device
- left public_ip: 172.18.201.10

- right local_ip: 172.18.202.10 # right side WAN IP

Imagine the following topology

Fig. 8: IPsec IKEv2 site2site VPN (source [./draw.io/vpn_s2s_ikev2.drawio](https://draw.io/vpn_s2s_ikev2.drawio))

Note: Don't get confused about the used /31 tunnel subnet. [RFC 3021](#) gives you additional information for using /31 subnets on point-to-point links.

```

Key Parameters:

- **authentication id/remote-id** - IKE identification is used for validation of VPN peer devices during IKE negotiation. If you do not configure local/ remote-identity, the device uses the IPv4 or IPv6 address that corresponds to the local/remote peer by default. In certain network setups (like ipsec interface with dynamic address, or behind the NAT), the IKE ID received from the peer does not match the IKE gateway configured on the device. This can lead to a Phase 1 validation failure. So, make sure to configure the local/remote id explicitly and ensure that the IKE ID is the same as the remote-identity configured on the peer device.
- **disable-route-autoinstall** - This option when configured disables the routes installed in the default

table 220 for site-to-site ipsec. It is mostly used with VTI configuration.

- `dead-peer-detection action = clear | hold | restart` - R_U_THERE notification messages (IKEv1) or empty INFORMATIONAL messages (IKEv2) are periodically sent in order to check the liveness of the IPsec peer. The values `clear`, `hold`, and `restart` all activate DPD and determine the action to perform on a timeout. With `clear` the connection is closed with no further actions taken. `hold` installs a trap policy, which will catch matching traffic and tries to re-negotiate the connection on demand. `restart` will immediately trigger an attempt to re-negotiate the connection.
- `close-action = none | clear | hold | restart` - defines the action to take if the remote peer unexpectedly closes a CHILD_SA (see above for meaning of values). A `closeaction` should not be used if the peer uses reauthentication or uniqueids.

For a responder, `close-action` or `dead-peer-detection` must not be enabled. For an initiator DPD with `restart` action, and `close-action 'restart'` is recommended in IKE profile.

8.14 VRF

VRF devices combined with `ip` rules provides the ability to create virtual routing and forwarding domains (aka VRFs, VRF-lite to be specific) in the Linux network stack. One use case is the multi-tenancy problem where each tenant has their own unique routing tables and in the very least need different default gateways.

8.14.1 Configuration

A VRF device is created with an associated route table. Network interfaces are then enslaved to a VRF device.

set vrf name <name>

Create new VRF instance with `<name>`. The name is used when placing individual interfaces into the VRF.

set vrf name <name> table <id>

Configured routing table `<id>` is used by VRF `<name>`.

Note: A routing table ID can not be modified once it is assigned. It can only be changed by deleting and re-adding the VRF instance.

set vrf bind-to-all

By default the scope of the port bindings for unbound sockets is limited to the default VRF. That is, it will not be matched by packets arriving on interfaces enslaved to a VRF and processes may bind to the same port if they bind to a VRF.

TCP & UDP services running in the default VRF context (ie., not bound to any VRF device) can work across all VRF domains by enabling this option.

Interfaces

When VRFs are used it is not only mandatory to create a VRF but also the VRF itself needs to be assigned to an interface.

set interfaces <dummy | ethernet | bonding | bridge | pppoe> <interface> vrf <name>

Assign interface identified by `<interface>` to VRF named `<name>`.

Routing

Note: VyOS 1.4 (sagitta) introduced dynamic routing support for VRFs.

Currently dynamic routing is supported for the following protocols:

- *BGP*
- *IS-IS*
- *OSPF*
- *Static*

The CLI configuration is same as mentioned in above articles. The only difference is, that each routing protocol used, must be prefixed with the *vrf name <name>* command.

Example

The following commands would be required to set options for a given dynamic routing protocol inside a given vrf:

- *BGP*: set vrf name <name> protocols bgp ...
- *IS-IS*: set vrf name <name> protocols isis ...
- *OSPF*: set vrf name <name> protocols ospf ...
- *Static*: set vrf name <name> protocols static ...

8.14.2 Operation

It is not sufficient to only configure a VRF but VRFs must be maintained, too. For VRF maintenance the following operational commands are in place.

show vrf

Lists VRFs that have been created

```
vyos@vyos:~$ show vrf
VRF name      state      mac address      flags
->interfaces
-----
->--
blue          up        00:53:12:d8:74:24  noarp, master, up, lower_up  dum200,
->eth0.302
red           up        00:53:de:02:df:aa  noarp, master, up, lower_up  dum100,
->eth0.300, bond0.100, peth0
```

Note: Command should probably be extended to list also the real interfaces assigned to this one VRF to get a better overview.

show vrf <name>

```
vyos@vyos:~$ show vrf name blue
VRF name      state      mac address      flags
--
->interfaces
-----
->--
blue          up          00:53:12:d8:74:24  noarp, master, up, lower_up  dum200,
->eth0.302
```

show ip route vrf <name>

Display IPv4 routing table for VRF identified by <name>.

```
vyos@vyos:~$ show ip route vrf blue
Codes: K - kernel route, C - connected, S - static, R - RIP,
       O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
       T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
       F - PBR, f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

VRF blue:
K  0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:00:50
S>* 172.16.0.0/16 [1/0] via 192.0.2.1, dum1, 00:00:02
C>* 192.0.2.0/24 is directly connected, dum1, 00:00:06
```

show ipv6 route vrf <name>

Display IPv6 routing table for VRF identified by <name>.

```
vyos@vyos:~$ show ipv6 route vrf red
Codes: K - kernel route, C - connected, S - static, R - RIPng,
       O - OSPFv3, I - IS-IS, B - BGP, N - NHRP, T - Table,
       v - VNC, V - VNC-Direct, A - Babel, D - SHARP, F - PBR,
       f - OpenFabric,
       > - selected route, * - FIB route, q - queued route, r - rejected route

VRF red:
K  ::/0 [255/8192] unreachable (ICMP unreachable), 00:43:20
C>* 2001:db8::/64 is directly connected, dum1, 00:02:19
C>* fe80::/64 is directly connected, dum1, 00:43:19
K>* ff00::/8 [0/256] is directly connected, dum1, 00:43:19
```

ping <host> vrf <name>

The ping command is used to test whether a network host is reachable or not.

Ping uses ICMP protocol's mandatory ECHO_REQUEST datagram to elicit an ICMP ECHO_RESPONSE from a host or gateway. ECHO_REQUEST datagrams (pings) will have an IP and ICMP header, followed by "struct timeval" and an arbitrary number of pad bytes used to fill out the packet.

When doing fault isolation with ping, you should first run it on the local host, to verify that the local network interface is up and running. Then, continue with hosts and gateways further down the road towards your destination. Round-trip time and packet loss statistics are computed.

Duplicate packets are not included in the packet loss calculation, although the round-trip time of these packets is used in calculating the minimum/ average/maximum round-trip time numbers.

Ping command can be interrupted at any given time using <Ctrl>+c- A brief statistic is shown afterwards.

```
vyos@vyos:~$ ping 192.0.2.1 vrf red
PING 192.0.2.1 (192.0.2.1) 56(84) bytes of data.
64 bytes from 192.0.2.1: icmp_seq=1 ttl=64 time=0.070 ms
64 bytes from 192.0.2.1: icmp_seq=2 ttl=64 time=0.078 ms
^C
--- 192.0.2.1 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 4ms
rtt min/avg/max/mdev = 0.070/0.074/0.078/0.004 ms
```

traceroute vrf <name> [ipv4 | ipv6] <host>

Displays the route packets taken to a network host utilizing VRF instance identified by <name>. When using the IPv4 or IPv6 option, displays the route packets taken to the given hosts IP address family. This option is useful when the host is specified as a hostname rather than an IP address.

8.14.3 Example

VRF route leaking

The following example topology was build using EVE-NG.

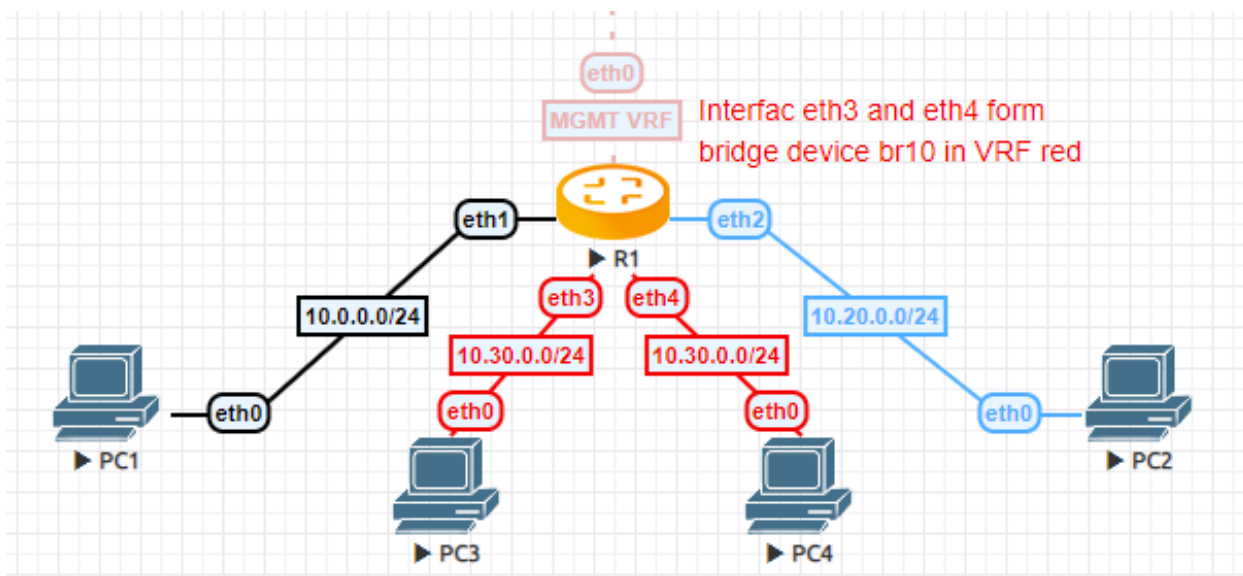

Fig. 9: VRF route leaking

- PC1 is in the default VRF and acting as e.g. a “fileserver”
- PC2 is in VRF blue which is the development department
- PC3 and PC4 are connected to a bridge device on router R1 which is in VRF red. Say this is the HR department.
- R1 is managed through an out-of-band network that resides in VRF mgmt

Configuration

```

set interfaces bridge br10 address '10.30.0.254/24'
set interfaces bridge br10 member interface eth3
set interfaces bridge br10 member interface eth4
set interfaces bridge br10 vrf 'red'

set interfaces ethernet eth0 address 'dhcp'
set interfaces ethernet eth0 vrf 'mgmt'
set interfaces ethernet eth1 address '10.0.0.254/24'
set interfaces ethernet eth2 address '10.20.0.254/24'
set interfaces ethernet eth2 vrf 'blue'

set protocols static route 10.20.0.0/24 interface eth2 vrf 'blue'
set protocols static route 10.30.0.0/24 interface br10 vrf 'red'

set service ssh disable-host-validation
set service ssh vrf 'mgmt'

set system name-servers-dhcp 'eth0'

set vrf name blue protocols static route 10.0.0.0/24 interface eth1 vrf
↪ 'default'
set vrf name blue table '3000'
set vrf name mgmt table '1000'
set vrf name red protocols static route 10.0.0.0/24 interface eth1 vrf
↪ 'default'
set vrf name red table '2000'

```

Operation

After committing the configuration we can verify all leaked routes are installed, and try to ICMP ping PC1 from PC3.

```

PCS> ping 10.0.0.1

84 bytes from 10.0.0.1 icmp_seq=1 ttl=63 time=1.943 ms
84 bytes from 10.0.0.1 icmp_seq=2 ttl=63 time=1.618 ms
84 bytes from 10.0.0.1 icmp_seq=3 ttl=63 time=1.745 ms

```

```

VPCS> show ip

NAME       : VPCS[1]
IP/MASK    : 10.30.0.1/24
GATEWAY    : 10.30.0.254
DNS        :
MAC        : 00:50:79:66:68:0f

```

VRF default routing table

```

vyos@R1:~$ show ip route

VRF red:
K>* 0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:07:57
S>* 10.0.0.0/24 [1/0] is directly connected, eth1 (vrf default), weight 1,
↪00:07:40
C>* 10.30.0.0/24 is directly connected, br10, 00:07:54
```

VRF blue routing table

```
vyos@R1:~$ show ip route vrf blue
Codes: K - kernel route, C - connected, S - static, R - RIP,
        O - OSPF, I - IS-IS, B - BGP, E - EIGRP, N - NHRP,
        T - Table, v - VNC, V - VNC-Direct, A - Babel, D - SHARP,
        F - PBR, f - OpenFabric,
        > - selected route, * - FIB route, q - queued, r - rejected, b -
↪backup

VRF blue:
K>* 0.0.0.0/0 [255/8192] unreachable (ICMP unreachable), 00:08:00
S>* 10.0.0.0/24 [1/0] is directly connected, eth1 (vrf default), weight 1,
↪00:07:44
C>* 10.20.0.0/24 is directly connected, eth2, 00:07:53
```

8.15 Zone Policy

In zone-based policy, interfaces are assigned to zones, and inspection policy is applied to traffic moving between the zones and acted on according to firewall rules. A Zone is a group of interfaces that have similar functions or features. It establishes the security borders of a network. A zone defines a boundary where traffic is subjected to policy restrictions as it crosses to another region of a network.

Key Points:

- A zone must be configured before an interface is assigned to it and an interface can be assigned to only a single zone.

- All traffic to and from an interface within a zone is permitted.
- All traffic between zones is affected by existing policies
- Traffic cannot flow between zone member interface and any interface that is not a zone member.
- You need 2 separate firewalls to define traffic: one for each direction.

Example: LAN Network is given SSH access to VyOS box.

Firewall rules:

```
set firewall name lan-local default-action 'drop'
set firewall name lan-local rule 1 action 'accept'
set firewall name lan-local rule 1 state established 'enable'
set firewall name lan-local rule 1 state related 'enable'
set firewall name lan-local rule 2 action 'drop'
set firewall name lan-local rule 2 state invalid 'enable'
set firewall name lan-local rule 2 log enable
set firewall name lan-local rule 100 action 'accept'
set firewall name lan-local rule 100 destination port '22'
set firewall name lan-local rule 100 log 'enable'
set firewall name lan-local rule 100 protocol 'tcp'
set firewall name local-lan default-action 'drop'
set firewall name local-lan rule 1 action 'accept'
set firewall name local-lan rule 1 state established 'enable'
set firewall name local-lan rule 1 state related 'enable'
set firewall name local-lan rule 2 action 'drop'
set firewall name local-lan rule 2 state invalid 'enable'
set firewall name local-lan rule 2 log enable
set firewall name local-lan rule 100 action 'accept'
set firewall name local-lan rule 100 destination address '192.168.0.0/24'
set firewall name local-lan rule 100 log 'enable'
set firewall name local-lan rule 100 protocol 'tcp'
```

Zone-policy Config:

```
set zone-policy zone lan default-action 'drop'
set zone-policy zone lan description 'Local Area Network'
set zone-policy zone lan interface 'eth2'
set zone-policy zone lan from local firewall name 'lan-local'
set zone-policy zone local default-action 'drop'
set zone-policy zone local description 'system-defined zone'
set zone-policy zone local from lan firewall name 'local-lan'
set zone-policy zone local local-zone
```

A detailed zone-based policy example is written in the [Configuration-Blueprints](#) section.

9.1 Information

VyOS features a rich set of operational level commands to retrieve arbitrary information about your running system.

9.1.1 Hardware

USB

In the past serial interface have been defined as ttySx and ttyUSBx where x was an instance number of the serial interface. It was discovered that from system boot to system boot the mapping of USB based serial interfaces will differ, depending which driver was loaded first by the operating system. This will become rather painful if you not only have serial interfaces for a console server connected but in addition also a serial backed *WWAN - Wireless Wide-Area-Network*.

To overcome this issue and the fact that in almost 50% of all cheap USB to serial converters there is no serial number programmed, the USB to serial interface is now directly identified by the USB root bridge and bus it connects to. This somehow mimics the new network interface definitions we see in recent Linux distributions.

For additional details you can refer to <https://phabricator.vyos.net/T2490>.

show hardware usb

Retrieve a tree like representation of all connected USB devices.

Note: If a device is unplugged and re-plugged it will receive a new Port, Dev, If identification.

```
vyos@vyos:~$ show hardware usb
/: Bus 03.Port 1: Dev 1, Class=root_hub, Driver=ehci-pci/2p, 480M
   |__ Port 1: Dev 2, If 0, Class=Hub, Driver=hub/4p, 480M
      |__ Port 3: Dev 4, If 0, Class=Vendor Specific Class, Driver=qcserial,
         ↳480M
```

(continues on next page)

(continued from previous page)

```

show version kernel

Return version number of the Linux Kernel used in this release.

```
vyos@vyos:~$ show version kernel
5.10.46-amd64-vyos
```

show version frr

Return version number of FRR (Free Range Routing - <https://frrouting.org/>) used in this release. This is the routing control plane and a successor to GNU Zebra and Quagga.

```
vyos@vyos:~$ show version frr
FRRouting 7.5.1-20210625-00-gf07d935a2 (vyos).
Copyright 1996-2005 Kunihiro Ishiguro, et al.
```

9.2 Boot Options

Warning: This function may be highly disruptive. It may cause major service interruption, so make sure you really need it and verify your input carefully.

VyOS has several kernel command line options to modify the normal boot process. To add an option, select the desired image in GRUB menu at load time, press **e**, edit the first line, and press **Ctrl-x** to boot when ready.

```

GNU GRUB  version 2.02~beta2-22+deb8u1

+-----+
|setparams 'VyOS 1.2.6-epal linux (Serial console)'

```

9.2.1 Specify custom config file

Tells the system to use specified file instead of `/config/config.boot`. If specified file does not exist or is not readable, fall back to default config. No additional verification is performed, so make sure you specify a valid config file.

```
vyos-config=/path/to/file
```

To load the *factory default* config, use:

```
vyos-config=/opt/vyatta/etc/config.boot.default
```

9.2.2 Disable specific boot process steps

These options disable some boot steps. Make sure you understand the *boot process* well before using them!

no-vyos-migrate Do not perform config migration.

no-vyos-firewall Do not initialize default firewall chains, renders any firewall configuration unusable.

- Saltstack
- startup scripts

10.1 VyOS API

For configuration and enabling the API see [HTTP-API](#)

10.1.1 Authentication

All endpoints only listen on HTTP POST requests and the API KEY must set as key in the formdata.

Below see one example for curl and one for python. The rest of the documentation is reduced to curl.

```
curl --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": [] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
import requests
url = "https://vyos/retrieve"
payload={ 'data': '{ "op": "showConfig", "path": [] }',
          'key': 'MY-HTTPS-API-PLAINTEXT-KEY'
        }
headers = {}
response = requests.request("POST", url, headers=headers, data=payload)
print(response.text)
```

10.1.2 API Endpoints

/retrieve

With the `retrieve` endpoint you get parts or the whole configuration.

To get the whole configuration, pass an empty list to the `path` field

```
curl --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": [] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
response (shorted)
{
  "success": true,
  "data": {
    "interfaces": {
      "ethernet": {
        "eth0": {
          "address": "dhcp",
          "duplex": "auto",
          "hw-id": "50:00:00:01:00:00",
          "speed": "auto"
        },
        "eth1": {
          "duplex": "auto",
          "hw-id": "50:00:00:01:00:01",
          "speed": "auto"
        },
        ...
      },
      "error": null
    }
  }
```

To only get a part of the configuration, for example `system syslog`.

```
curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "showConfig", "path": ["system", "syslog"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'
```

```
response:
{
  "success": true,
  "data": {
    "global": {
      "facility": {
        "all": {
          "level": "info"
        },
        "protocols": {
          "level": "debug"
        }
      }
    },
    "error": null
  }
```

if you just want the Value of a multi-valued node, use the `returnValues` operation.

For example, get the addresses of a dum0 interface.

```
curl -k --location --request POST 'https://vyos/retrieve' \
--form data='{ "op": "returnValues", "path": ["interfaces", "dummy", "dum0", "address"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": [
    "10.10.10.10/24",
    "10.10.10.11/24",
    "10.10.10.12/24"
  ],
  "error": null
}
```

/image

To add or delete an image, use the /image endpoint.

add an image

```
curl -k --location --request POST 'https://vyos/image' \
--form data='{ "op": "add", "url": "https://downloads.vyos.io/rolling/current/amd64/
vyos-rolling-latest.iso" }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response (shorted):
{
  "success": true,
  "data": "Trying to fetch ISO file from https://downloads.vyos.io/rolling-latest.
iso\n
  ...
  Setting up grub configuration...\nDone.\n",
  "error": null
}
```

delete an image, for example 1.3-rolling-202006070117

```
curl -k --location --request POST 'https://vyos/image' \
--form data='{ "op": "delete", "name": "1.3-rolling-202006070117" }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "Deleting the \"1.3-rolling-202006070117\" image...\nDone\n",
  "error": null
}
```

/show

The /show endpoint is to show everything in the operational mode.

For example, show which images are installed.

```
curl -k --location --request POST 'https://vyos/show' \
--form data='{ "op": "show", "path": ["system", "image"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "The system currently has the following image(s) installed:\n\n
          1: 1.4-rolling-202102280559 (default boot)\n
          2: 1.4-rolling-202102230218\n
          3: 1.3-beta-202102210443\n\n",
  "error": null
}
```

/generate

The generate endpoint run a generate command.

```
curl -k --location --request POST 'https://vyos/generate' \
--form data='{ "op": "generate", "path": ["wireguard", "default-keypair"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "",
  "error": null
}
```

/configure

You can pass a set, delete or comment command to the /configure endpoint.

set a single command

```
curl -k --location --request POST 'https://vyos/configure' \
--form data='{ "op": "set", "path": ["interfaces", "dummy", "dum1", "address", "10.11.
↪0.1/32"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": null,
  "error": null
}
```

delete a single command

```
curl -k --location --request POST 'https://vyos/configure' \
--form data='{ "op": "delete", "path": ["interfaces", "dummy", "dum1", "address", "10.
↪11.0.1/32"] }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
```

(continues on next page)

(continued from previous page)

```
{
  "success": true,
  "data": null,
  "error": null
}
```

The API pushes every request to a session and commit it. But some of VyOS components like DHCP and PPPoE Servers, IPSec, VXLAN, and other tunnels require full configuration for commit. The endpoint will process multiple commands when you pass them as a list to the data field.

```
curl -k --location --request POST 'https://vyos/configure' \
--form data='[{"op": "set", "path": ["interfaces", "vxlan", "vxlan1", "remote", "203.0.113.99"]}, {"op": "set", "path": ["interfaces", "vxlan", "vxlan1", "vni", "1"]}]' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": null,
  "error": null
}
```

/config-file

The endpoint /config-file is to save or load a configuration.

Save a running configuration to the startup configuration. When you don't specify the file when saving, it saves to /config/config.boot.

```
curl -k --location --request POST 'https://vyos/config-file' \
--form data='{ "op": "save" }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "Saving configuration to '/config/config.boot'...\nDone\n",
  "error": null
}
```

Save a running configuration to a file.

```
curl -k --location --request POST 'https://vyos/config-file' \
--form data='{ "op": "save", "file": "/config/test.config" }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": "Saving configuration to '/config/test.config'...\nDone\n",
  "error": null
}
```

To Load a configuration file.

```
curl -k --location --request POST 'https://vyos/config-file' \
--form data='{ "op": "load", "file": "/config/test.config" }' \
--form key='MY-HTTPS-API-PLAINTEXT-KEY'

response:
{
  "success": true,
  "data": null,
  "error": null
}
```

10.2 Ansible

VyOS supports configuration via ansible. Need to install `ansible` and `python3-paramiko` module

Structure of files

```
.
├── ansible.cfg
├── files
│   └── id_rsa_docker.pub
├── hosts
└── main.yml
```

10.2.1 File contents

`ansible.cfg`

```
[defaults]
host_key_checking = no
retry_files_enabled = False
ANSIBLE_INVENTORY_UNPARSED_FAILED = true
```

`id_rsa_docker.pub`. Needs to declare only public key exactly.

```
AAAAB3NzaC1yc2EAAAADAQABAAQCoDgfhQJuJRFWJijHn7ZinZ3NWp4hWVrt7HFcvn0kgtP/5PeCtMt
```

`hosts`

```
[vyos_hosts]
r11 ansible_ssh_host=192.0.2.11

[vyos_hosts:vars]
ansible_python_interpreter=/usr/bin/python3
ansible_user=vyos
ansible_ssh_pass=vyos
ansible_network_os=vyos
ansible_connection=network_cli
```

`main.yml`

```
---
```

(continues on next page)

(continued from previous page)

```
- hosts: r11

connection: network_cli
gather_facts: 'no'

tasks:
  - name: Configure remote r11
    vyos_config:
      lines:
        - set system host-name r11
        - set system name-server 203.0.113.254
        - set service ssh disable-host-validation
        - set system login user vyos authentication public-keys docker@work type_
↪ssh-rsa
        - set system login user vyos authentication public-keys docker@work key "{{_
↪lookup('file', 'id_rsa_docker.pub') }}"
        - set system time-zone America/Los_Angeles
        - set interfaces ethernet eth0 description WAN
```

10.2.2 Run ansible

```
$ ansible-playbook -i hosts main.yml

PLAY [r11]_
↪*****

TASK [Configure remote r11]_
↪*****
changed: [r11]

PLAY RECAP_
↪*****
r11                : ok=1    changed=1    unreachable=0    failed=0    _
↪skipped=0         rescued=0    ignored=0
```

10.3 Command Scripting

VyOS supports executing configuration and operational commands non-interactively from shell scripts.

To include VyOS specific functions and aliases you need to source `/opt/vyatta/etc/functions/script-template` files at the top of your script.

```
#!/bin/vbash
source /opt/vyatta/etc/functions/script-template
exit
```

10.3.1 Run configuration commands

Configuration commands are executed just like from a normal config session. For example, if you want to disable a BGP peer on VRRP transition to backup:

```
#!/bin/vbash
source /opt/vyatta/etc/functions/script-template
configure
set protocols bgp local-as 65536
set protocols bgp neighbor 192.168.2.1 shutdown
commit
exit
```

10.3.2 Run operational commands

Unlike a normal configuration session, all operational commands must be prepended with `run`, even if you haven't created a session with `configure`.

```
#!/bin/vbash
source /opt/vyatta/etc/functions/script-template
run show interfaces
exit
```

10.3.3 Other script languages

If you want to script the configs in a language other than bash you can have your script output commands and then source them in a bash script.

Here is a simple example:

```
#!/usr/bin/env python
print "delete firewall group address-group somehosts"
print "set firewall group address-group somehosts address '192.0.2.3'"
print "set firewall group address-group somehosts address '203.0.113.55'"
```

```
#!/bin/vbash
source /opt/vyatta/etc/functions/script-template
configure
source < /config/scripts/setfirewallgroup.py
commit
```

10.3.4 Executing Configuration Scripts

There is a pitfall when working with configuration scripts. It is tempting to call configuration scripts with “`sudo`” (i.e., temporary root permissions), because that's the common way on most Linux platforms to call system commands.

On VyOS this will cause the following problem: After modifying the configuration via script like this once, it is not possible to manually modify the config anymore:

```
sudo ./myscript.sh # Modifies config
configure
set ... # Any configuration parameter
```

This will result in the following error message: `Set failed` If this happens, a reboot is required to be able to edit the config manually again.

To avoid these problems, the proper way is to call a script with the `vyattacfg` group, e.g., by using the `sg` (switch group) command:

```
sg vyattacfg -c ./myscript.sh
```

To make sure that a script is not accidentally called without the `vyattacfg` group, the script can be safeguarded like this:

```
if [ "$(id -g -n)" != 'vyattacfg' ] ; then
    exec sg vyattacfg -c "/bin/vbash $(readlink -f $0) $@"
fi
```

10.3.5 Executing pre-hooks/post-hooks Scripts

VyOS has the ability to run custom scripts before and after each commit

The default directories where your custom Scripts should be located are:

```
/config/scripts/commit/pre-hooks.d - Directory with scripts that run before
                                     each commit.

/config/scripts/commit/post-hooks.d - Directory with scripts that run after
                                     each commit.
```

Scripts are run in alphabetical order. Their names must consist entirely of ASCII upper- and lower-case letters, ASCII digits, ASCII underscores, and ASCII minus-hyphens. No other characters are allowed.

Note: Custom scripts are not executed with root privileges (Use `sudo` inside if this is necessary).

A simple example is shown below, where the `ops` command executed in the post-hook script is “show interfaces”.

```
vyos@vyos# set interfaces ethernet eth1 address 192.0.2.3/24
vyos@vyos# commit
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
eth0           198.51.100.10/24 u/u
eth1           192.0.2.3/24    u/u
eth2           -               u/u
eth3           -               u/u
lo             203.0.113.5/24  u/u
```

10.3.6 Preconfig on boot

The `/config/scripts/vyos-preconfig-bootup.script` script is called on boot before the VyOS configuration during boot process.

Any modifications were done to work around unfixed bugs and implement enhancements that are not complete in the VyOS system can be placed here.

The default file looks like this:

```
#!/bin/sh
# This script is executed at boot time before VyOS configuration is applied.
# Any modifications required to work around unfixed bugs or use
# services not available through the VyOS CLI system can be placed here.
```

10.3.7 Postconfig on boot

The `/config/scripts/vyos-postconfig-bootup.script` script is called on boot after the VyOS configuration is fully applied.

Any modifications were done to work around unfixed bugs and implement enhancements that are not complete in the VyOS system can be placed here.

The default file looks like this:

```
#!/bin/sh
# This script is executed at boot time after VyOS configuration is fully
# applied. Any modifications required to work around unfixed bugs or use
# services not available through the VyOS CLI system can be placed here.
```

Hint: For configuration/upgrade management issues, modification of this script should be the last option. Always try to find solutions based on CLI commands first.

10.4 VyOS cloud-init

Cloud and virtualized instances of VyOS are initialized using the industry-standard cloud-init. Via cloud-init, the system performs tasks such as injecting SSH keys and configuring the network. In addition, the user can supply a custom configuration at the time of instance launch.

10.4.1 Config Sources

VyOS support three types of config sources.

- Metadata - Metadata is sourced by the cloud platform or hypervisor. In some clouds, there is implemented as an HTTP endpoint at <http://169.254.169.254>.
- Network configuration - This config source informs the system about the network settings like IP addresses, routes, DNS. Available only in several cloud and virtualization platforms.
- User-data - User-data is specified by the user. This config source offers the ability to insert any CLI configuration commands into the configuration before the first boot.

10.4.2 User-data

Major cloud providers offer a means of providing user-data at the time of instance launch. It can be provided as plain text or as base64-encoded text, depending on cloud provider. Also, it can be compressed using gzip, which makes sense with a long configuration commands list, because of the hard limit to ~16384 bytes for the whole user-data.

The easiest way to configure the system via user-data is the Cloud-config syntax described below.

10.4.3 Cloud-config modules

In VyOS, by default, enabled only two modules:

- `write_files` - this module allows to insert any files into the filesystem before the first boot, for example, pre-generated encryption keys, certificates, or even a whole `config.boot` file.

- `vyos_userdata` - the module accepts a list of CLI configuration commands in a `vyos_config_commands` section, which gives an easy way to configure the system during deployment.

10.4.4 cloud-config file format

A cloud-config document is written in YAML. The file must begin with `#cloud-config` line. The key used to designate a VyOS configuration is `vyos_config_commands`. What follows is VyOS configuration using the “set-style” syntax. Both “set” and “delete” commands are supported.

Commands requirements:

- one command per line
- if command ends in a value, it must be inside single quotes
- a single-quote symbol is not allowed inside command or value

The commands list produced by the `show configuration commands` command on a VyOS router should comply with all the requirements, so it is easy to get a proper commands list by copying it from another router.

The configuration specified in the cloud-config document overwrites default configuration values and values configured via Metadata.

Here is an example cloud-config.

```
#cloud-config
vyos_config_commands:
- set system host-name 'vyos-prod-ashburn'
- set system ntp server 1.pool.ntp.org
- set system ntp server 2.pool.ntp.org
- delete interfaces ethernet eth1 address 'dhcp'
- set interfaces ethernet eth1 address '192.0.2.247/24'
- set protocols static route 198.51.100.0/24 next-hop '192.0.2.1'
```

10.4.5 System Defaults/Fallbacks

These are the VyOS defaults and fallbacks.

- SSH is configured on port 22
- `vyos/vyos` credentials if no others specified by data source
- DHCP on first Ethernet interface if no network configuration is provided

All of these can be overridden using the configuration in user-data.

10.4.6 Troubleshooting

If you encounter problems, verify that the cloud-config document contains valid YAML. Online resources such as <https://yamlvalidator.com/> provide a simple tool for validating YAML.

cloud-init logs to `/var/log/cloud-init.log`. This file can be helpful in determining why the configuration varies from what you expect. You can fetch the most important data filtering output for `vyos` keyword:

```
sudo grep vyos /var/log/cloud-init.log
```

Sometimes things break or don't work as expected. This section describes several troubleshooting tools provided by VyOS that can help when something goes wrong.

11.1 Connectivity Tests

11.1.1 Basic Connectivity Tests

Verifying connectivity can be done with the familiar *ping* and *traceroute* commands. The options for each are shown (the options for each command were displayed using the built-in help as described in the *Command Line Interface* section and are omitted from the output here):

ping <destination>

Send ICMP echo requests to destination host. There are multiple options to ping, inkl. VRF support.

```
vyos@vyos:~$ ping 10.1.1.1
Possible completions:
  <Enter>          Execute the current command
  adaptive         Ping options
  allow-broadcast
  audible
  bypass-route
  count
  deadline
  do-not-fragment
  flood
  interface
  interval
  mark
  no-loopback
  numeric
  pattern
```

(continues on next page)

(continued from previous page)

```

quiet
record-route
size
timestamp
tos
ttl
verbose
vrf

```

traceroute <destination>

Trace path to target.

```

vyos@vyos:~$ traceroute
Possible completions:
<hostname>      Track network path to specified node
<x.x.x.x>
<h:h:h:h:h:h:h>
ipv4             Track network path to <hostname|IPv4 address>
ipv6            Track network path to <hostname|IPv6 address>

```

11.1.2 Advanced Connectivity Tests**monitor traceroute <destination>**

However, another helper is available which combines ping and traceroute into a single tool. An example of its output is shown:

```

vyos@vyos:~$ mtr 10.62.212.12

                                My traceroute  [v0.85]
vyos (0.0.0.0)
Keys:  Help    Display mode  Restart statistics   Order of fields  quit
      Packets
      Pings
Host      Loss%  Snt   Last   Avg    Best  Wrst  StDev
1. 10.11.110.4      0.0%   34    0.5    0.5    0.4    0.8    0.1
2. 10.62.255.184    0.0%   34    1.1    1.0    0.9    1.4    0.1
3. 10.62.255.71     0.0%   34    1.4    1.4    1.3    2.0    0.1
4. 10.62.212.12     0.0%   34    1.6    1.6    1.6    1.7    0.0

```

Note: The output consumes the screen and will replace your command prompt.

Several options are available for changing the display output. Press *h* to invoke the built in help system. To quit, just press *q* and you'll be returned to the VyOS command prompt.

11.1.3 IPv6 Topology Discovery

IPv6 uses different techniques to discover its Neighbors/topology.

Router Discovery

force ipv6-rd interface <interface> [address <ipv6-address>]

Discover routers via eth0.

Example:

```
vyos@vyos:~$ force ipv6-rd interface eth0
Soliciting ff02::2 (ff02::2) on eth0...

Hop limit           :           60 (           0x3c)
Stateful address conf. :           No
Stateful other conf.  :           No
Mobile home agent    :           No
Router preference    :           high
Neighbor discovery proxy :           No
Router lifetime      :           1800 (0x00000708) seconds
Reachable time       :           unspecified (0x00000000)

Source link-layer address: 00:98:2B:F8:3F:11
from fe80::298:2bff:fef8:3f11
```

Neighbor Discovery

force ipv6-nd interface <interface> address <ipv6-address>

Example:

```
vyos@vyos:~$ force ipv6-nd interface eth0 address fc00:470:f1cd:101::1

Soliciting fc00:470:f1cd:101::1 (fc00:470:f1cd:101::1) on eth0...
Target link-layer address: 00:98:2B:F8:3F:11 from fc00:470:f1cd:101::1
```

11.2 Interface names

If you find the names of your interfaces have changed, this could be because your MAC addresses have changed.

- For example, you have a VyOS VM with 4 Ethernet interfaces named eth0, eth1, eth2 and eth3. Then, you migrate your VyOS VM to a different host and find your interfaces now are eth4, eth5, eth6 and eth7.

One way to fix this issue **taking control of the MAC addresses** is:

Log into VyOS and run this command to display your interface settings.

```
show interfaces detail
```

Take note of MAC addresses.

Now, in order to update a MAC address in the configuration, run this command specifying the interface name and MAC address you want.

```
set interfaces eth0 hw-id 00:0c:29:da:a4:fe
```

If it is a VM, go into the settings of the host and set the MAC address to the settings found in the config.boot file. You can also set the MAC to static if the host allows so.

- Another example could be when cloning VyOS VMs in GNS3 and you get into the same issue: interface names have changed.

And **a more generic way to fix it** is just deleting every MAC address at the configuration file of the cloned machine. They will be correctly regenerated automatically.

11.3 Monitoring

VyOS features several monitoring tools.

```
vyos@vyos:~$ monitor
Possible completions:
  bandwidth      Monitor interface bandwidth in real time
  bandwidth-test
                  Initiate or wait for bandwidth test
  cluster        Monitor clustering service
  command        Monitor an operational mode command (refreshes every 2 seconds)
  conntrack-sync
                  Monitor conntrack-sync
  content-inspection
                  Monitor Content-Inspection
  dhcp           Monitor Dynamic Host Control Protocol (DHCP)
  dns            Monitor a Domain Name Service (DNS) daemon
  firewall       Monitor Firewall
  https         Monitor the Secure Hypertext Transfer Protocol (HTTPS) service
  lldp          Monitor Link Layer Discovery Protocol (LLDP) daemon
  log           Monitor last lines of messages file
  nat           Monitor network address translation (NAT)
  ndp           Monitor the NDP information received by the router through the device
  openvpn       Monitor OpenVPN
  protocol       Monitor routing protocols
  snmp          Monitor Simple Network Management Protocol (SNMP) daemon
  stop-all      Stop all current background monitoring processes
  traceroute    Monitor the path to a destination in realtime
  traffic       Monitor traffic dumps
  vpn           Monitor VPN
  vrrp          Monitor Virtual Router Redundancy Protocol (VRRP)
  webproxy      Monitor Webproxy service
```

11.3.1 Traffic Dumps

To monitor interface traffic, issue the `monitor traffic interface <name>` command, replacing *<name>* with your chosen interface.

```
vyos@vyos:~$ monitor traffic interface eth0
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
```

(continues on next page)

(continued from previous page)

```
listening on eth0, link-type EN10MB (Ethernet), capture size 262144 bytes
15:54:28.581601 IP 192.168.0.1 > vyos: ICMP echo request, id 1870, seq 3848, length 64
15:54:28.581660 IP vyos > 192.168.0.1: ICMP echo reply, id 1870, seq 3848, length 64
15:54:29.583399 IP 192.168.0.1 > vyos: ICMP echo request, id 1870, seq 3849, length 64
15:54:29.583454 IP vyos > 192.168.0.1: ICMP echo reply, id 1870, seq 3849, length 64
^C
4 packets captured
4 packets received by filter
0 packets dropped by kernel
vyos@vyos:~$
```

To quit monitoring, press *Ctrl-c* and you'll be returned to the VyOS command prompt.

Traffic can be filtered and saved.

```
vyos@vyos:~$ monitor traffic interface eth0
Possible completions:
  <Enter>      Execute the current command
  filter      Monitor traffic matching filter conditions
  save        Save traffic dump from an interface to a file
```

11.3.2 Interface Bandwidth Usage

to take a quick view on the used bandwidth of an interface use the `monitor bandwidth` command

```
vyos@vyos:~$ monitor bandwidth interface eth0
```

show the following:

```

      B                               (RX Bytes/second)
198.00 .|....|.....
165.00 .|....|.....
132.00 ||...|.....
 99.00 ||...|.....
 66.00 |||||...
 33.00 |||||...
      1    5    10   15   20   25   30   35   40   45   50   55   60

      KiB                             (TX Bytes/second)
 3.67 .....|.....
 3.06 .....|.....
 2.45 .....|.....
 1.84 .....|.....
 1.22 .....|.....
 0.61 :::::|.....
      1    5    10   15   20   25   30   35   40   45   50   55   60
```

11.3.3 Interface Performance

To take a look on the network bandwidth between two nodes, the `monitor bandwidth-test` command is used to run `iperf`.

```
vyos@vyos:~$ monitor bandwidth-test
Possible completions:
  accept      Wait for bandwidth test connections (port TCP/5001)
  initiate    Initiate a bandwidth test
```

- The `accept` command opens a listening `iperf` server on TCP Port 5001
- The `initiate` command connects to that server to perform the test.

```
vyos@vyos:~$ monitor bandwidth-test initiate
Possible completions:
  <hostname>   Initiate a bandwidth test to specified host (port TCP/5001)
  <x.x.x.x>
  <h:h:h:h:h:h:h>
```

11.3.4 Monitor command

The `monitor command` command allows you to repeatedly run a command to view a continuously refreshed output. The command is run and output every 2 seconds, allowing you to monitor the output continuously without having to re-run the command. This can be useful to follow routing adjacency formation.

```
vyos@router:~$ monitor command "show interfaces"
```

Will clear the screen and show you the output of `show interfaces` every 2 seconds.

```
Every 2.0s: /opt/vyatta/bin/vyatta-op-cmd-wrapper    Sun Mar 26 02:49:46 2019

Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down
Interface      IP Address      S/L  Description
-----
eth0            192.168.1.1/24   u/u
eth0.5          198.51.100.4/24  u/u  WAN
lo              127.0.0.1/8      u/u
                ::1/128
vti0            172.25.254.2/30  u/u
vti1            172.25.254.9/30  u/u
```

11.4 Terminal/Console

Sometimes you need to clear counters or statistics to troubleshoot better.

To do this use the `clear` command in Operational mode.

to clear the console output

```
vyos@vyos:~$ clear console
```

to clear interface counters

```
# clear all interfaces
vyos@vyos:~$ clear interface ethernet counters
# clear specific interface
vyos@vyos:~$ clear interface ethernet eth0 counters
```

The command follow the same logic as the `set` command in configuration mode.

```
# clear all counters of a interface type
vyos@vyos:~$ clear interface <interface_type> counters
# clear counter of a interface in interface_type
vyos@vyos:~$ clear interface <interface_type> <interace_name> counters
```

to clear counters on firewall rulesets or single rules

```
vyos@vyos:~$ clear firewall name <ipv4 ruleset name> counters
vyos@vyos:~$ clear firewall name <ipv4 ruleset name> rule <rule#> counters

vyos@vyos:~$ clear firewall ipv6-name <ipv6 ruleset name> counters
vyos@vyos:~$ clear firewall ipv6-name <ipv6 ruleset name> rule <rule#> counters
```

11.5 System Information

11.5.1 Boot Steps

VyOS 1.2 uses [Debian Jessie](#) as the base Linux operating system. Jessie was the first version of Debian that uses [systemd](#) as the default init system.

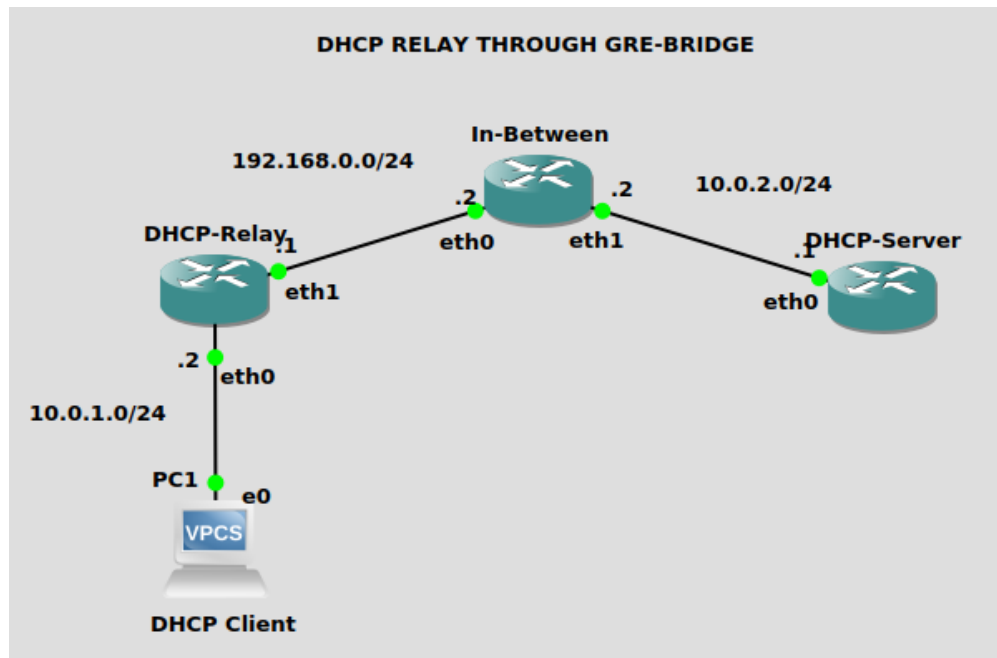

These are the boot steps for VyOS 1.2

1. The BIOS loads Grub (or isolinux for the Live CD)
2. Grub then starts the Linux boot and loads the Linux Kernel `/boot/vmlinuz`
3. Kernel Launches Systemd `/lib/systemd/systemd`
4. Systemd loads the VyOS service file `/lib/systemd/system/vyos-router.service`
5. The service file launches the VyOS router init script `/usr/libexec/vyos/init/vyos-router` - this is part of the [vyatta-cfg](#) Debian package
 1. Starts [FRR](#) - successor to [GNU Zebra](#) and [Quagga](#)
 2. Initialises the boot configuration file - copies over `config.boot.default` if there is no configuration
 3. Runs the configuration migration, if the configuration is for an older version of VyOS
 4. Runs The pre-config script, if there is one `/config/scripts/vyos-preconfig-bootup.script`
 5. If the config file was upgraded, runs any post upgrade scripts `/config/scripts/post-upgrade.d`
 6. Starts `rl-system` and `firewall`
 7. Mounts the `/boot` partition
 8. The boot configuration file is then applied by `/opt/vyatta/sbin/vyatta-boot-config-loader/opt/vyatta/etc/config/config.boot`
 1. The config loader script writes log entries to `/var/log/vyatta-config-loader.log`
 9. Runs `telinit q` to tell the init system to reload `/etc/inittab`
 10. Finally it runs the post-config script `/config/scripts/vyos-postconfig-bootup.script`

This chapter contains various configuration examples:

```

12.2 Zone-Policy example

12.2.1 Native IPv4 and IPv6

We have three networks.

```
WAN - 172.16.10.0/24, 2001:0DB8:0:9999::0/64  
LAN - 192.168.100.0/24, 2001:0DB8:0:AAAA::0/64  
DMZ - 192.168.200.0/24, 2001:0DB8:0:BBBB::0/64
```

This specific example is for a router on a stick, but is very easily adapted for however many NICs you have:

- Internet - 192.168.200.100 - TCP/80
- Internet - 192.168.200.100 - TCP/443
- Internet - 192.168.200.100 - TCP/25
- Internet - 192.168.200.100 - TCP/53
- VyOS acts as DHCP, DNS forwarder, NAT, router and firewall.
- 192.168.200.200/2001:0DB8:0:BBBB::200 is an internal/external DNS, web and mail (SMTP/IMAP) server.
- 192.168.100.10/2001:0DB8:0:AAAA::10 is the administrator's console. It can SSH to VyOS.
- LAN and DMZ hosts have basic outbound access: Web, FTP, SSH.
- LAN can access DMZ resources.
- DMZ cannot access LAN resources.
- Inbound WAN connect to DMZ host.

Logical

Physical

The VyOS interface is assigned the .1/1 address of their respective networks. WAN is on VLAN 10, LAN on VLAN 20, and DMZ on VLAN 30.

It will look something like this:

```
interfaces {
    ethernet eth0 {
        duplex auto
        hw-id 00:53:ed:6e:2a:92
        smp_affinity auto
        speed auto
        vif 10 {
            address 172.16.10.1/24
            address 2001:db8:0:9999::1/64
        }
        vif 20 {
            address 192.168.100.1/24
            address 2001:db8:0:AAAA::1/64
        }
    }
}
```

(continues on next page)

(continued from previous page)

```

    }
    vif 30 {
        address 192.168.200.1/24
        address 2001:db8:0:BBBB::1/64
    }
}
loopback lo {
}
}

```

12.2.2 Zones Basics

Each interface is assigned to a zone. The interface can be physical or virtual such as tunnels (VPN, PPTP, GRE, etc) and are treated exactly the same.

Traffic flows from zone A to zone B. That flow is what I refer to as a zone-pair-direction. eg. A->B and B->A are two zone-pair-destinations.

Rulesets are created per zone-pair-direction.

I name rule sets to indicate which zone-pair-direction they represent. eg. ZoneA-ZoneB or ZoneB-ZoneA. LAN-DMZ, DMZ-LAN.

In VyOS, you have to have unique Ruleset names. In the event of overlap, I add a “-6” to the end of v6 rulesets. eg. LAN-DMZ, LAN-DMZ-6. This allows for each auto-completion and uniqueness.

In this example we have 4 zones. LAN, WAN, DMZ, Local. The local zone is the firewall itself.

If your computer is on the LAN and you need to SSH into your VyOS box, you would need a rule to allow it in the LAN-Local ruleset. If you want to access a webpage from your VyOS box, you need a rule to allow it in the Local-LAN ruleset.

In rules, it is good to keep them named consistently. As the number of rules you have grows, the more consistency you have, the easier your life will be.

```

Rule 1 - State Established, Related
Rule 2 - State Invalid
Rule 100 - ICMP
Rule 200 - Web
Rule 300 - FTP
Rule 400 - NTP
Rule 500 - SMTP
Rule 600 - DNS
Rule 700 - DHCP
Rule 800 - SSH
Rule 900 - IMAPS

```

The first two rules are to deal with the idiosyncrasies of VyOS and iptables.

Zones and Rulesets both have a default action statement. When using Zone-Policies, the default action is set by the zone-policy statement and is represented by rule 10000.

It is good practice to log both accepted and denied traffic. It can save you significant headaches when trying to troubleshoot a connectivity issue.

To add logging to the default rule, do:

```
set firewall name <ruleSet> enable-default-log
```

By default, iptables does not allow traffic for established sessions to return, so you must explicitly allow this. I do this by adding two rules to every ruleset. 1 allows established and related state packets through and rule 2 drops and logs invalid state packets. We place the established/related rule at the top because the vast majority of traffic on a network is established and the invalid rule to prevent invalid state packets from mistakenly being matched against other rules. Having the most matched rule listed first reduces CPU load in high volume environments. Note: I have filed a bug to have this added as a default action as well.

“It is important to note, that you do not want to add logging to the established state rule as you will be logging both the inbound and outbound packets for each session instead of just the initiation of the session. Your logs will be massive in a very short period of time.”

In VyOS you must have the interfaces created before you can apply it to the zone and the rulesets must be created prior to applying it to a zone-policy.

I create/configure the interfaces first. Build out the rulesets for each zone-pair-direction which includes at least the three state rules. Then I setup the zone-policies.

Zones do not allow for a default action of accept; either drop or reject. It is important to remember this because if you apply an interface to a zone and commit, any active connections will be dropped. Specifically, if you are SSH'd into VyOS and add local or the interface you are connecting through to a zone and do not have rulesets in place to allow SSH and established sessions, you will not be able to connect.

The following are the rules that were created for this example (may not be complete), both in IPv4 and IPv6. If there is no IP specified, then the source/destination address is not explicit.

```
WAN - DMZ:192.168.200.200 - tcp/80
WAN - DMZ:192.168.200.200 - tcp/443
WAN - DMZ:192.168.200.200 - tcp/25
WAN - DMZ:192.168.200.200 - tcp/53
WAN - DMZ:2001:0DB8:0:BBBB::200 - tcp/80
WAN - DMZ:2001:0DB8:0:BBBB::200 - tcp/443
WAN - DMZ:2001:0DB8:0:BBBB::200 - tcp/25
WAN - DMZ:2001:0DB8:0:BBBB::200 - tcp/53

DMZ - Local - tcp/53
DMZ - Local - tcp/123
DMZ - Local - tcp/67,68

LAN - Local - tcp/53
LAN - Local - tcp/123
LAN - Local - tcp/67,68
LAN:192.168.100.10 - Local - tcp/22
LAN:2001:0DB8:0:AAAA::10 - Local - tcp/22

LAN - WAN - tcp/80
LAN - WAN - tcp/443
LAN - WAN - tcp/22
LAN - WAN - tcp/20,21

DMZ - WAN - tcp/80
DMZ - WAN - tcp/443
DMZ - WAN - tcp/22
DMZ - WAN - tcp/20,21
DMZ - WAN - tcp/53
DMZ - WAN - udp/53
```

(continues on next page)

(continued from previous page)

```

Local - WAN - tcp/80
Local - WAN - tcp/443
Local - WAN - tcp/20,21

Local - DMZ - tcp/25
Local - DMZ - tcp/67,68
Local - DMZ - tcp/53
Local - DMZ - udp/53

Local - LAN - tcp/67,68

LAN - DMZ - tcp/80
LAN - DMZ - tcp/443
LAN - DMZ - tcp/993
LAN:2001:0DB8:0:AAAA::10 - DMZ:2001:0DB8:0:BBBB::200 - tcp/22
LAN:192.168.100.10 - DMZ:192.168.200.200 - tcp/22

```

Since we have 4 zones, we need to setup the following rulesets.

```

Lan-wan
Lan-local
Lan-dmz
Wan-lan
Wan-local
Wan-dmz
Local-lan
Local-wan
Local-dmz
Dmz-lan
Dmz-wan
Dmz-local

```

Even if the two zones will never communicate, it is a good idea to create the zone-pair-direction rulesets and set enable-default-log. This will allow you to log attempts to access the networks. Without it, you will never see the connection attempts.

This is an example of the three base rules.

```

name wan-lan {
    default-action drop
    enable-default-log
    rule 1 {
        action accept
        state {
            established enable
            related enable
        }
    }
    rule 2 {
        action drop
        log enable
        state {
            invalid enable
        }
    }
}

```

Here is an example of an IPv6 DMZ-WAN ruleset.

```
ipv6-name dmz-wan-6 {
  default-action drop
  enable-default-log
  rule 1 {
    action accept
    state {
      established enable
      related enable
    }
  }
  rule 2 {
    action drop
    log enable
    state {
      invalid enable
    }
  }
  rule 100 {
    action accept
    log enable
    protocol ipv6-icmp
  }
  rule 200 {
    action accept
    destination {
      port 80,443
    }
    log enable
    protocol tcp
  }
  rule 300 {
    action accept
    destination {
      port 20,21
    }
    log enable
    protocol tcp
  }
  rule 500 {
    action accept
    destination {
      port 25
    }
    log enable
    protocol tcp
    source {
      address 2001:db8:0:BBBB::200
    }
  }
  rule 600 {
    action accept
    destination {
      port 53
    }
    log enable
    protocol tcp_udp
    source {
```

(continues on next page)

(continued from previous page)

```

        address 2001:db8:0:BBBB::200
    }
}
rule 800 {
    action accept
    destination {
        port 22
    }
    log enable
    protocol tcp
}
}

```

Once you have all of your rulesets built, then you need to create your zone-policy.

Start by setting the interface and default action for each zone.

```

set zone-policy zone dmz default-action drop
set zone-policy zone dmz interface eth0.30

```

In this case, we are setting the v6 ruleset that represents traffic sourced from the LAN, destined for the DMZ. Because the zone-policy firewall syntax is a little awkward, I keep it straight by thinking of it backwards.

```

set zone-policy zone dmz from lan firewall ipv6-name lan-dmz-6

```

DMZ-LAN policy is LAN-DMZ. You can get a rhythm to it when you build out a bunch at one time.

In the end, you will end up with something like this config. I took out everything but the Firewall, Interfaces, and zone-policy sections. It is long enough as is.

12.2.3 IPv6 Tunnel

If you are using a IPv6 tunnel from HE.net or someone else, the basis is the same except you have two WAN interfaces. One for v4 and one for v6.

You would have 5 zones instead of just 4 and you would configure your v6 ruleset between your tunnel interface and your LAN/DMZ zones instead of to the WAN.

LAN, WAN, DMZ, local and TUN (tunnel)

v6 pairs would be:

```

lan-tun
lan-local
lan-dmz
tun-lan
tun-local
tun-dmz
local-lan
local-tun
local-dmz
dmz-lan
dmz-tun
dmz-local

```

Notice, none go to WAN since WAN wouldn't have a v6 address on it.

You would have to add a couple of rules on your wan-local ruleset to allow protocol 41 in.

Something like:

```
rule 400 {
    action accept
    destination {
        address 172.16.10.1
    }
    log enable
    protocol 41
    source {
        address ip.of.tunnel.broker
    }
}
```

12.3 BGP IPv6 unnumbered with extended nexthop

General information can be found in the *BGP* chapter.

12.3.1 Configuration

- Router A:

```
set protocols bgp local-as 64496
set protocols bgp address-family ipv4-unicast redistribute connected
set protocols bgp address-family ipv6-unicast redistribute connected
set protocols bgp neighbor eth1 interface v6only
set protocols bgp neighbor eth1 interface v6only peer-group 'fabric'
set protocols bgp neighbor eth2 interface v6only
set protocols bgp neighbor eth2 interface v6only peer-group 'fabric'
set protocols bgp parameters bestpath as-path multipath-relax
set protocols bgp parameters bestpath compare-routerid
set protocols bgp parameters default no-ipv4-unicast
set protocols bgp parameters router-id '192.168.0.1'
set protocols bgp peer-group fabric address-family ipv4-unicast
set protocols bgp peer-group fabric address-family ipv6-unicast
set protocols bgp peer-group fabric capability extended-nexthop
set protocols bgp peer-group fabric remote-as 'external'
```

- Router B:

```
set protocols bgp local-as 64499
set protocols bgp address-family ipv4-unicast redistribute connected
set protocols bgp address-family ipv6-unicast redistribute connected
set protocols bgp neighbor eth1 interface v6only
set protocols bgp neighbor eth1 interface v6only peer-group 'fabric'
set protocols bgp neighbor eth2 interface v6only
set protocols bgp neighbor eth2 interface v6only peer-group 'fabric'
set protocols bgp parameters bestpath as-path multipath-relax
set protocols bgp parameters bestpath compare-routerid
set protocols bgp parameters default no-ipv4-unicast
set protocols bgp parameters router-id '192.168.0.2'
set protocols bgp peer-group fabric address-family ipv4-unicast
set protocols bgp peer-group fabric address-family ipv6-unicast
set protocols bgp peer-group fabric capability extended-nexthop
set protocols bgp peer-group fabric remote-as 'external'
```

12.3.2 Results

• Router A:

```
vyos@vyos:~$ show interfaces
Codes: S - State, L - Link, u - Up, D - Down, A - Admin Down

12.5 Route-Based Site-to-Site VPN to Azure (BGP over IKEv2/IPsec)

This guide shows an example of a route-based IKEv2 site-to-site VPN to Azure using VTI and BGP for dynamic routing updates.

For redundant / active-active configurations see [Route-Based Redundant Site-to-Site VPN to Azure \(BGP over IKEv2/IPsec\)](#)

12.5.1 Prerequisites

- A pair of Azure VNet Gateways deployed in active-passive configuration with BGP enabled.
- A local network gateway deployed in Azure representing the Vyos device, matching the below Vyos settings except for address space, which only requires the Vyos private IP, in this example 10.10.0.5/32
- A connection resource deployed in Azure linking the Azure VNet gateway and the local network gateway representing the Vyos device.

12.5.2 Example

WAN Interface	eth0
On-premises address space	10.10.0.0/16
Azure address space	10.0.0.0/16
Vyos public IP	198.51.100.3
Vyos private IP	10.10.0.5
Azure VNet Gateway public IP	203.0.113.2
Azure VNet Gateway BGP IP	10.0.0.4
Pre-shared key	ch00s3-4-s3cur3-psk
Vyos ASN	64499
Azure ASN	65540

12.5.3 Vyos configuration

- Configure the IKE and ESP settings to match a subset of those supported by Azure:

```
set vpn ipsec esp-group AZURE compression 'disable'
set vpn ipsec esp-group AZURE lifetime '3600'
set vpn ipsec esp-group AZURE mode 'tunnel'
set vpn ipsec esp-group AZURE pfs 'dh-group2'
set vpn ipsec esp-group AZURE proposal 1 encryption 'aes256'
set vpn ipsec esp-group AZURE proposal 1 hash 'sha1'

set vpn ipsec ike-group AZURE dead-peer-detection action 'restart'
set vpn ipsec ike-group AZURE dead-peer-detection interval '15'
set vpn ipsec ike-group AZURE dead-peer-detection timeout '30'
set vpn ipsec ike-group AZURE ikev2-reauth 'yes'
set vpn ipsec ike-group AZURE key-exchange 'ikev2'
set vpn ipsec ike-group AZURE lifetime '28800'
set vpn ipsec ike-group AZURE proposal 1 dh-group '2'
set vpn ipsec ike-group AZURE proposal 1 encryption 'aes256'
set vpn ipsec ike-group AZURE proposal 1 hash 'sha1'
```

- Enable IPsec on eth0

```
set vpn ipsec ipsec-interfaces interface 'eth0'
```

- Configure a VTI with a dummy IP address

```
set interfaces vti vti1 address '10.10.1.5/32'
set interfaces vti vti1 description 'Azure Tunnel'
```

- Clamp the VTI's MSS to 1350 to avoid PMTU blackholes.

```
set firewall options interface vti1 adjust-mss 1350
```

- Configure the VPN tunnel

```
set vpn ipsec site-to-site peer 203.0.113.2 authentication id '198.51.100.3'
set vpn ipsec site-to-site peer 203.0.113.2 authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer 203.0.113.2 authentication pre-shared-secret 'ch00s3-
↪4-s3cur3-psk'
set vpn ipsec site-to-site peer 203.0.113.2 authentication remote-id '203.0.113.2'
set vpn ipsec site-to-site peer 203.0.113.2 connection-type 'respond'
set vpn ipsec site-to-site peer 203.0.113.2 description 'AZURE PRIMARY TUNNEL'
set vpn ipsec site-to-site peer 203.0.113.2 ike-group 'AZURE'
set vpn ipsec site-to-site peer 203.0.113.2 ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer 203.0.113.2 local-address '10.10.0.5'
set vpn ipsec site-to-site peer 203.0.113.2 vti bind 'vti1'
set vpn ipsec site-to-site peer 203.0.113.2 vti esp-group 'AZURE'
```

- **Important:** Add an interface route to reach Azure's BGP listener

```
set protocols static route 10.0.0.4/32 interface vti1
```

- Configure your BGP settings

```
set protocols bgp local-as 64499
set protocols bgp neighbor 10.0.0.4 remote-as '65540'
set protocols bgp neighbor 10.0.0.4 address-family ipv4-unicast soft-reconfiguration
↪'inbound'
set protocols bgp neighbor 10.0.0.4 timers holdtime '30'
set protocols bgp neighbor 10.0.0.4 timers keepalive '10'
```

- **Important:** Disable connected check

```
set protocols bgp neighbor 10.0.0.4 disable-connected-check
```

12.6 Route-Based Redundant Site-to-Site VPN to Azure (BGP over IKEv2/IPsec)

This guide shows an example of a redundant (active-active) route-based IKEv2 site-to-site VPN to Azure using VTI and BGP for dynamic routing updates.

12.6.1 Prerequisites

- A pair of Azure VNet Gateways deployed in active-active configuration with BGP enabled.
- A local network gateway deployed in Azure representing the Vyos device, matching the below Vyos settings except for address space, which only requires the Vyos private IP, in this example 10.10.0.5/32
- A connection resource deployed in Azure linking the Azure VNet gateway and the local network gateway representing the Vyos device.

12.6.2 Example

WAN Interface	eth0
On-premises address space	10.10.0.0/16
Azure address space	10.0.0.0/16
Vyos public IP	198.51.100.3
Vyos private IP	10.10.0.5
Azure VNet Gateway 1 public IP	203.0.113.2
Azure VNet Gateway 2 public IP	203.0.113.3
Azure VNet Gateway BGP IP	10.0.0.4,10.0.0.5
Pre-shared key	ch00s3-4-s3cur3-psk
Vyos ASN	64499
Azure ASN	65540

12.6.3 Vyos configuration

- Configure the IKE and ESP settings to match a subset of those supported by Azure:

```
set vpn ipsec esp-group AZURE compression 'disable'
set vpn ipsec esp-group AZURE lifetime '3600'
set vpn ipsec esp-group AZURE mode 'tunnel'
set vpn ipsec esp-group AZURE pfs 'dh-group2'
set vpn ipsec esp-group AZURE proposal 1 encryption 'aes256'
set vpn ipsec esp-group AZURE proposal 1 hash 'sha1'

set vpn ipsec ike-group AZURE dead-peer-detection action 'restart'
set vpn ipsec ike-group AZURE dead-peer-detection interval '15'
set vpn ipsec ike-group AZURE dead-peer-detection timeout '30'
set vpn ipsec ike-group AZURE ikev2-reauth 'yes'
set vpn ipsec ike-group AZURE key-exchange 'ikev2'
set vpn ipsec ike-group AZURE lifetime '28800'
set vpn ipsec ike-group AZURE proposal 1 dh-group '2'
set vpn ipsec ike-group AZURE proposal 1 encryption 'aes256'
set vpn ipsec ike-group AZURE proposal 1 hash 'sha1'
```

- Enable IPsec on eth0

```
set vpn ipsec ipsec-interfaces interface 'eth0'
```

- Configure two VTIs with a dummy IP address each

```
set interfaces vti vti1 address '10.10.1.5/32'
set interfaces vti vti1 description 'Azure Primary Tunnel'

set interfaces vti vti2 address '10.10.1.6/32'
set interfaces vti vti2 description 'Azure Secondary Tunnel'
```

- Clamp the VTI's MSS to 1350 to avoid PMTU blackholes.

```
set firewall options interface vti1 adjust-mss 1350
set firewall options interface vti2 adjust-mss 1350
```

- Configure the VPN tunnels

```

set vpn ipsec site-to-site peer 203.0.113.2 authentication id '198.51.100.3'
set vpn ipsec site-to-site peer 203.0.113.2 authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer 203.0.113.2 authentication pre-shared-secret 'ch00s3-
↪4-s3cur3-psk'
set vpn ipsec site-to-site peer 203.0.113.2 authentication remote-id '203.0.113.2'
set vpn ipsec site-to-site peer 203.0.113.2 connection-type 'respond'
set vpn ipsec site-to-site peer 203.0.113.2 description 'AZURE PRIMARY TUNNEL'
set vpn ipsec site-to-site peer 203.0.113.2 ike-group 'AZURE'
set vpn ipsec site-to-site peer 203.0.113.2 ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer 203.0.113.2 local-address '10.10.0.5'
set vpn ipsec site-to-site peer 203.0.113.2 vti bind 'vti1'
set vpn ipsec site-to-site peer 203.0.113.2 vti esp-group 'AZURE'

set vpn ipsec site-to-site peer 203.0.113.3 authentication id '198.51.100.3'
set vpn ipsec site-to-site peer 203.0.113.3 authentication mode 'pre-shared-secret'
set vpn ipsec site-to-site peer 203.0.113.3 authentication pre-shared-secret 'ch00s3-
↪4-s3cur3-psk'
set vpn ipsec site-to-site peer 203.0.113.3 authentication remote-id '203.0.113.3'
set vpn ipsec site-to-site peer 203.0.113.3 connection-type 'respond'
set vpn ipsec site-to-site peer 203.0.113.3 description 'AZURE SECONDARY TUNNEL'
set vpn ipsec site-to-site peer 203.0.113.3 ike-group 'AZURE'
set vpn ipsec site-to-site peer 203.0.113.3 ikev2-reauth 'inherit'
set vpn ipsec site-to-site peer 203.0.113.3 local-address '10.10.0.5'
set vpn ipsec site-to-site peer 203.0.113.3 vti bind 'vti2'
set vpn ipsec site-to-site peer 203.0.113.3 vti esp-group 'AZURE'

```

- **Important:** Add an interface route to reach both Azure's BGP listeners

```

set protocols static route 10.0.0.4/32 interface vti1
set protocols static route 10.0.0.5/32 interface vti2

```

- **Configure your BGP settings**

```

set protocols bgp local-as 64499
set protocols bgp neighbor 10.0.0.4 remote-as '65540'
set protocols bgp neighbor 10.0.0.4 address-family ipv4-unicast soft-reconfiguration
↪'inbound'
set protocols bgp neighbor 10.0.0.4 timers holdtime '30'
set protocols bgp neighbor 10.0.0.4 timers keepalive '10'

set protocols bgp neighbor 10.0.0.5 remote-as '65540'
set protocols bgp neighbor 10.0.0.5 address-family ipv4-unicast soft-reconfiguration
↪'inbound'
set protocols bgp neighbor 10.0.0.5 timers holdtime '30'
set protocols bgp neighbor 10.0.0.5 timers keepalive '10'

```

- **Important:** Disable connected check, otherwise the routes learned from Azure will not be imported into the routing table.

```

set protocols bgp neighbor 10.0.0.4 disable-connected-check
set protocols bgp neighbor 10.0.0.5 disable-connected-check

```

12.7 Tunnelbroker.net (IPv6)

This guide walks through the setup of <https://www.tunnelbroker.net/> for an IPv6 Tunnel.

12.7.1 Prerequisites

- A public, routable IPv4 address. This does not necessarily need to be static, but you will need to update the tunnel endpoint when/if your IP address changes, which can be done with a script and a scheduled task.
- Account at <https://www.tunnelbroker.net/>
- Requested a “Regular Tunnel”. You want to choose a location that is closest to your physical location for the best response time.

12.7.2 Setup initial tunnel

Set up initial IPv6 tunnel. Replace the field below from the fields on the tunnel information page.

```
conf
set interfaces tunnel tun0 address Client_IPv6_from_Tunnelbroker # This will be
↪your VyOS install's public IPv6 address
set interfaces tunnel tun0 description 'HE.NET IPv6 Tunnel'
set interfaces tunnel tun0 encapsulation 'sit'
set interfaces tunnel tun0 source-address Client_IPv4_from_Tunnelbroker # This is
↪your public IP
set interfaces tunnel tun0 mtu '1472'
set interfaces tunnel tun0 multicast 'disable'
set interfaces tunnel tun0 remote Server_IPv4_from_Tunnelbroker # This is the IP of
↪the Tunnelbroker server
set protocols static route6 ::/0 interface tun0 # Tell all traffic to go over this
↪tunnel
commit
```

If your WAN connection is over PPPoE, you may need to set the MTU on the above tunnel lower than 1472.

At this point you should be able to ping an IPv6 address, try pinging Google:

```
ping6 -c2 2001:4860:4860::8888

64 bytes from 2001:4860:4860::8888: icmp_seq=1 ttl=57 time=21.7 ms
64 bytes from 2001:4860:4860::8888: icmp_seq=2 ttl=57 time=21.1 ms

--- 2001:4860:4860::8888 ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 1001ms
rtt min/avg/max/mdev = 21.193/21.459/21.726/0.304 ms
```

Assuming the pings are successful, you need to add some DNS servers. Some options:

```
set system name-server 2001:4860:4860::8888 # Google
set system name-server 2001:4860:4860::8844 # Google
set system name-server 2606:4700:4700::1111 # Cloudflare
set system name-server 2606:4700:4700::1001 # Cloudflare
commit
```

You should now be able to ping something by IPv6 DNS name:

```
# ping6 -c2 one.one.one.one
PING one.one.one.one(one.one.one.one) 56 data bytes
64 bytes from one.one.one.one: icmp_seq=1 ttl=58 time=16.8 ms
64 bytes from one.one.one.one: icmp_seq=2 ttl=58 time=17.4 ms
```

(continues on next page)

(continued from previous page)

```
--- one.one.one.one ping statistics ---
2 packets transmitted, 2 received, 0% packet loss, time 1001ms
rtt min/avg/max/mdev = 16.880/17.153/17.426/0.273 ms
```

Assuming everything works, you can proceed to the client configuration

12.7.3 LAN Configuration

At this point, your VyOS install should have full IPv6, but now your LAN devices need access.

With Tunnelbroker.net, you have two options:

- Routed /64. This is the default assignment. In IPv6-land, it's good for a single "LAN", and is somewhat equivalent to a /24. Example: `2001:470:xxxx:xxxx::/64`
- Routed /48. This is something you can request by clicking the "Assign /48" link in the Tunnelbroker.net tunnel config. It allows you to have up to 65k LANs. Example: `2001:470:xxxx::/48`

Unlike IPv4, IPv6 is really not designed to be broken up smaller than /64. So if you ever want to have multiple LANs, VLANs, DMZ, etc, you'll want to ignore the assigned /64, and request the /48 and use that.

12.7.4 Single LAN Setup

Single LAN setup where eth1 is your LAN interface. Use the /64 (all the xxxx should be replaced with the information from your *Routed /64* tunnel):

```
set interfaces ethernet eth1 address '2001:470:xxxx:xxxx::1/64'
set service router-advert interface eth1 name-server '2001:4860:4860::8888'
set service router-advert interface eth1 name-server '2001:4860:4860::8844'
set service router-advert interface eth1 prefix 2001:470:xxxx:xxxx::/64
```

Please note, 'autonomous-flag' and 'on-link-flag' are enabled by default, 'valid-lifetime' and 'preferred-lifetime' are set to default values of 30 days and 4 hours respectively.

This accomplishes a few things:

- Sets your LAN interface's IP address
- Enables router advertisements. This is an IPv6 alternative for DHCP (though DHCPv6 can still be used). With RAs, Your devices will automatically find the information they need for routing and DNS.

12.7.5 Multiple LAN/DMZ Setup

In this, you use the *Routed /48* information. This allows you to assign a different /64 to every interface, LAN, or even device. Or you could break your network into smaller chunks like /56 or /60.

The format of these addresses:

- `2001:470:xxxx::/48`: The whole subnet. xxxx should come from Tunnelbroker.
- `2001:470:xxxx:1::/64`: A subnet suitable for a LAN
- `2001:470:xxxx:2::/64`: Another subnet
- `2001:470:xxxx:ffff::/64`: The last usable /64 subnet.

In the above examples, 1,2,ffff are all chosen by you. You can use 1-ffff (1-65535).

So, when your LAN is eth1, your DMZ is eth2, your cameras are on eth3, etc:

```
set interfaces ethernet eth1 address '2001:470:xxxx:1::1/64'
set service router-advert interface eth1 name-server '2001:4860:4860::8888'
set service router-advert interface eth1 name-server '2001:4860:4860::8844'
set service router-advert interface eth1 prefix 2001:470:xxxx:1::/64

set interfaces ethernet eth2 address '2001:470:xxxx:2::1/64'
set service router-advert interface eth2 name-server '2001:4860:4860::8888'
set service router-advert interface eth2 name-server '2001:4860:4860::8844'
set service router-advert interface eth2 prefix 2001:470:xxxx:2::/64

set interfaces ethernet eth3 address '2001:470:xxxx:3::1/64'
set service router-advert interface eth3 name-server '2001:4860:4860::8888'
set service router-advert interface eth3 name-server '2001:4860:4860::8844'
set service router-advert interface eth3 prefix 2001:470:xxxx:3::/64
```

Please note, ‘autonomous-flag’ and ‘on-link-flag’ are enabled by default, ‘valid-lifetime’ and ‘preferred-lifetime’ are set to default values of 30 days and 4 hours respectively.

12.7.6 Firewall

Finally, don’t forget the *Firewall*. The usage is identical, except for instead of *set firewall name NAME*, you would use *set firewall ipv6-name NAME*.

Similarly, to attach the firewall, you would use *set interfaces ethernet eth0 firewall in ipv6-name* or *set zone-policy zone LOCAL from WAN firewall ipv6-name*.

12.8 High Availability Walkthrough

This document walks you through a complete HA setup of two VyOS machines. This design is based on a VM as the primary router and a physical machine as a backup, using VRRP, BGP, OSPF, and conntrack sharing.

This document aims to walk you through setting everything up, so at a point where you can reboot any machine and not lose more than a few seconds worth of connectivity.

12.8.1 Design

This is based on a real-life production design. One of the complex issues is ensuring you have redundant data INTO your network. We do this with a pair of Cisco Nexus switches and using Virtual PortChannels that are spanned across them. As a bonus, this also allows for complete switch failure without an outage. How you achieve this yourself is left as an exercise to the reader. But our setup is documented here.

Walkthrough suggestion

The `commit` command is implied after every section. If you make an error, `commit` will warn you and you can fix it before getting too far into things. Please ensure you commit early and commit often.

If you are following through this document, it is strongly suggested you complete the entire document, **ONLY** doing the virtual router1 steps, and then come back and walk through it **AGAIN** on the backup hardware router.

This ensures you don't go too fast or miss a step. However, it will make your life easier to configure the fixed IP address and default route now on the hardware router.

Example Network

In this document, we have been allocated 203.0.113.0/24 by our upstream provider, which we are publishing on VLAN100.

They want us to establish a BGP session to their routers on 192.0.2.11 and 192.0.2.12 from our routers 192.0.2.21 and 192.0.2.22. They are AS 65550 and we are AS 65551.

Our routers are going to have a floating IP address of 203.0.113.1, and use .2 and .3 as their fixed IPs.

We are going to use 10.200.201.0/24 for an 'internal' network on VLAN201.

When traffic is originated from the 10.200.201.0/24 network, it will be masqueraded to 203.0.113.1

For connection between sites, we are running a WireGuard link to two REMOTE routers and using OSPF over those links to distribute routes. That remote site is expected to send traffic from anything in 10.201.0.0/16

VLANs

These are the vlans we will be using:

- 50: Upstream, using the 192.0.2.0/24 network allocated by them.
- 100: 'Public' network, using our 203.0.113.0/24 network.
- 201: 'Internal' network, using 10.200.201.0/24

Hardware

- switch1 (Nexus 10gb Switch)
- switch2 (Nexus 10gb Switch)
- compute1 (VMware ESXi 6.5)
- compute2 (VMware ESXi 6.5)
- compute3 (VMware ESXi 6.5)
- router2 (Random 1RU machine with 4 NICs)

Note that router1 is a VM that runs on one of the compute nodes.

Network Cabling

- From Datacenter - This connects into port 1 on both switches, and is tagged as VLAN 50
- Cisco VPC Crossconnect - Ports 39 and 40 bonded between each switch
- Hardware Router - Port 8 of each switch
- compute1 - Port 9 of each switch
- compute2 - Port 10 of each switch
- compute3 - Port 11 of each switch

This is ignoring the extra Out-of-band management networking, which should be on totally different switches, and a different feed into the rack, and is out of scope of this.

Note: Our implementation uses VMware's Distributed Port Groups, which allows VMware to use LACP. This is a part of the ENTERPRISE licence, and is not available on a free licence. If you are implementing this and do not have access to DPGs, you should not use VMware, and use some other virtualization platform instead.

12.8.2 Basic Setup (via console)

Create your router1 VM. So it can withstand a VM Host failing or a network link failing. Using VMware, this is achieved by enabling vSphere DRS, vSphere Availability, and creating a Distributed Port Group that uses LACP.

Many other Hypervisors do this, and I'm hoping that this document will be expanded to document how to do this for others.

Create an 'All VLANs' network group, that passes all trunked traffic through to the VM. Attach this network group to router1 as eth0.

Note: VMware: You must DISABLE SECURITY on this Port group. Make sure that Promiscuous Mode, MAC address changes and Forged transmits are enabled. All of these will be done as part of failover.

Bonding on Hardware Router

Create a LACP bond on the hardware router. We are assuming that eth0 and eth1 are connected to port 8 on both switches, and that those ports are configured as a Port-Channel.

```
set interfaces bonding bond0 description 'Switch Port-Channel'
set interfaces bonding bond0 hash-policy 'layer2'
set interfaces bonding bond0 member interface 'eth0'
set interfaces bonding bond0 member interface 'eth1'
set interfaces bonding bond0 mode '802.3ad'
```

Assign external IP addresses

VLAN 100 and 201 will have floating IP addresses, but VLAN50 does not, as this is talking directly to upstream. Create our IP address on vlan50.

For the hardware router, replace eth0 with bond0. As (almost) every command is identical, this will not be specified unless different things need to be performed on different hosts.

```
set interfaces ethernet eth0 vif 50 address '192.0.2.21/24'
```

In this case, the hardware router has a different IP, so it would be

```
set interfaces ethernet bond0 vif 50 address '192.0.2.22/24'
```

Add (temporary) default route

It is assumed that the routers provided by upstream are capable of acting as a default router, add that as a static route.

```
set protocols static route 0.0.0.0/0 next-hop 192.0.2.11
commit
save
```

Enable SSH

Enable SSH so you can now SSH into the routers, rather than using the console.

```
set service ssh
commit
save
```

At this point, you should be able to SSH into both of them, and will no longer need access to the console (unless you break something!)

12.8.3 VRRP Configuration

We are setting up VRRP so that it does NOT fail back when a machine returns into service, and it prioritizes router1 over router2.

Internal Network

This has a floating IP address of 10.200.201.1/24, using virtual router ID 201. The difference between them is the interface name, hello-source-address, and peer-address.

router1

```
set interfaces ethernet eth0 vif 201 address 10.200.201.2/24
set high-availability vrrp group int hello-source-address '10.200.201.2'
set high-availability vrrp group int interface 'eth0.201'
set high-availability vrrp group int peer-address '10.200.201.3'
set high-availability vrrp group int no-preempt
set high-availability vrrp group int priority '200'
set high-availability vrrp group int virtual-address '10.200.201.1/24'
set high-availability vrrp group int vrid '201'
```

router2

```
set interfaces ethernet bond0 vif 201 address 10.200.201.3/24
set high-availability vrrp group int hello-source-address '10.200.201.3'
set high-availability vrrp group int interface 'bond0.201'
set high-availability vrrp group int peer-address '10.200.201.2'
set high-availability vrrp group int no-preempt
set high-availability vrrp group int priority '100'
set high-availability vrrp group int virtual-address '10.200.201.1/24'
set high-availability vrrp group int vrid '201'
```

Public Network

This has a floating IP address of 203.0.113.1/24, using virtual router ID 113. The virtual router ID is just a random number between 1 and 254, and can be set to whatever you want. Best practices suggest you try to keep them unique enterprise-wide.

router1

```
set interfaces ethernet eth0 vif 100 address 203.0.113.2/24
set high-availability vrrp group public hello-source-address '203.0.113.2'
set high-availability vrrp group public interface 'eth0.100'
set high-availability vrrp group public peer-address '203.0.113.3'
set high-availability vrrp group public no-preempt
set high-availability vrrp group public priority '200'
set high-availability vrrp group public virtual-address '203.0.113.1/24'
set high-availability vrrp group public vrid '113'
```

router2

```
set interfaces ethernet bond0 vif 100 address 203.0.113.3/24
set high-availability vrrp group public hello-source-address '203.0.113.3'
set high-availability vrrp group public interface 'bond0.100'
set high-availability vrrp group public peer-address '203.0.113.2'
set high-availability vrrp group public no-preempt
set high-availability vrrp group public priority '100'
set high-availability vrrp group public virtual-address '203.0.113.1/24'
set high-availability vrrp group public vrid '113'
```

Create VRRP sync-group

The sync group is used to replicate connection tracking. It needs to be assigned to a random VRRP group, and we are creating a sync group called `sync` using the `vrrp group int`.

```
set high-availability vrrp sync-group sync member 'int'
```

Testing

At this point, you should be able to see both IP addresses when you run `show interfaces`, and `show vrrp` should show both interfaces in MASTER state (and SLAVE state on router2).

```
vyos@router1:~$ show vrrp
Name      Interface      VRID  State    Last Transition
-----
int       eth0.201        201   MASTER   100s
public    eth0.100        113   MASTER   200s
vyos@router1:~$
```

You should be able to ping to and from all the IPs you have allocated.

12.8.4 NAT and conntrack-sync

Masquerade Traffic originating from 10.200.201.0/24 that is heading out the public interface.

Note: We explicitly exclude the primary upstream network so that BGP or OSPF traffic doesn't accidentally get NAT'ed.

```
set nat source rule 10 destination address '!192.0.2.0/24'
set nat source rule 10 outbound-interface 'eth0.50'
set nat source rule 10 source address '10.200.201.0/24'
set nat source rule 10 translation address '203.0.113.1'
```

Configure conntrack-sync and disable helpers

Most conntrack modules cause more problems than they're worth, especially in a complex network. Turn them off by default, and if you need to turn them on later, you can do so.

```
set system conntrack modules ftp disable
set system conntrack modules gre disable
set system conntrack modules nfs disable
set system conntrack modules pptp disable
set system conntrack modules sip disable
set system conntrack modules tftp disable
```

Now enable replication between nodes. Replace eth0.201 with bond0.201 on the hardware router.

```
set service conntrack-sync accept-protocol 'tcp,udp,icmp'
set service conntrack-sync event-listen-queue-size '8'
set service conntrack-sync failover-mechanism vrrp sync-group 'sync'
set service conntrack-sync interface eth0.201
set service conntrack-sync mcast-group '224.0.0.50'
set service conntrack-sync sync-queue-size '8'
```

Testing

The simplest way to test is to look at the connection tracking stats on the standby hardware router with the command `show conntrack-sync statistics`. The numbers should be very close to the numbers on the primary router.

When you have both routers up, you should be able to establish a connection from a NAT'ed machine out to the internet, reboot the active machine, and that connection should be preserved, and will not drop out.

12.8.5 OSPF Over WireGuard

Wireguard doesn't have the concept of an up or down link, due to its design. This complicates AND simplifies using it for network transport, as for reliable state detection you need to use SOMETHING to detect when the link is down.

If you use a routing protocol itself, you solve two problems at once. This is only a basic example, and is provided as a starting point.

Configure Wireguard

There is plenty of instructions and documentation on setting up Wireguard. The only important thing you need to remember is to only use one WireGuard interface per OSPF connection.

We use small /30's from 10.254.60/24 for the point-to-point links.

router1

Replace the 203.0.113.3 with whatever the other router's IP address is.

```

set interfaces wireguard wg01 address '10.254.60.1/30'
set interfaces wireguard wg01 description 'router1-to-offsite1'
set interfaces wireguard wg01 peer OFFSITE1 allowed-ips '0.0.0.0/0'
set interfaces wireguard wg01 peer OFFSITE1 endpoint '203.0.113.3:50001'
set interfaces wireguard wg01 peer OFFSITE1 persistent-keepalive '15'
set interfaces wireguard wg01 peer OFFSITE1 pubkey 'GEFMOWzAyau42/
↪HwdwfXnrfHdIISQF8YHj35rOgSZ0o='
set interfaces wireguard wg01 port '50001'
set protocols ospf interface wg01 authentication md5 key-id 1 md5-key
↪'i360KoCwUGZvPq7e'
set protocols ospf interface wg01 cost '11'
set protocols ospf interface wg01 dead-interval '5'
set protocols ospf interface wg01 hello-interval '1'
set protocols ospf interface wg01 network 'point-to-point'
set protocols ospf interface wg01 priority '1'
set protocols ospf interface wg01 retransmit-interval '5'
set protocols ospf interface wg01 transmit-delay '1'

```

offsite1

This is connecting back to the STATIC IP of router1, not the floating.

```

set interfaces wireguard wg01 address '10.254.60.2/30'
set interfaces wireguard wg01 description 'offsite1-to-router1'
set interfaces wireguard wg01 peer ROUTER1 allowed-ips '0.0.0.0/0'
set interfaces wireguard wg01 peer ROUTER1 endpoint '192.0.2.21:50001'
set interfaces wireguard wg01 peer ROUTER1 persistent-keepalive '15'
set interfaces wireguard wg01 peer ROUTER1 pubkey 'CKwMV3ZaLntMule2Kd3G7UyVBR7zE8/
↪qoZgLB82EE2Q='
set interfaces wireguard wg01 port '50001'
set protocols ospf interface wg01 authentication md5 key-id 1 md5-key
↪'i360KoCwUGZvPq7e'
set protocols ospf interface wg01 cost '11'
set protocols ospf interface wg01 dead-interval '5'
set protocols ospf interface wg01 hello-interval '1'
set protocols ospf interface wg01 network 'point-to-point'
set protocols ospf interface wg01 priority '1'
set protocols ospf interface wg01 retransmit-interval '5'
set protocols ospf interface wg01 transmit-delay '1'

```

Test WireGuard

Make sure you can ping 10.254.60.1 and .2 from both routers.

Create Export Filter

We only want to export the networks we know. Always do a whitelist on your route filters, both importing and exporting. A good rule of thumb is **‘If you are not the default router for a network, don’t advertise it’**. This means we explicitly do not want to advertise the 192.0.2.0/24 network (but do want to advertise 10.200.201.0 and 203.0.113.0, which we ARE the default route for). This filter is applied to `redistribute connected`. If we WERE to advertise it, the remote machines would see 192.0.2.21 available via their default route, establish the connection, and then OSPF would say ‘192.0.2.0/24 is available via this tunnel’, at which point the tunnel would break, OSPF would drop the routes, and then 192.0.2.0/24 would be reachable via default again. This is called ‘flapping’.

```

set policy access-list 150 description 'Outbound OSPF Redistribution'
set policy access-list 150 rule 10 action 'permit'
set policy access-list 150 rule 10 destination any
set policy access-list 150 rule 10 source inverse-mask '0.0.0.255'
set policy access-list 150 rule 10 source network '10.200.201.0'
set policy access-list 150 rule 20 action 'permit'
set policy access-list 150 rule 20 destination any
set policy access-list 150 rule 20 source inverse-mask '0.0.0.255'
set policy access-list 150 rule 20 source network '203.0.113.0'
set policy access-list 150 rule 100 action 'deny'
set policy access-list 150 rule 100 destination any
set policy access-list 150 rule 100 source any

```

Create Import Filter

We only want to import networks we know. Our OSPF peer should only be advertising networks in the 10.201.0.0/16 range. Note that this is an INVERSE MATCH. You deny in access-list 100 to accept the route.

```

set policy access-list 100 description 'Inbound OSPF Routes from Peers'
set policy access-list 100 rule 10 action 'deny'
set policy access-list 100 rule 10 destination any
set policy access-list 100 rule 10 source inverse-mask '0.0.255.255'
set policy access-list 100 rule 10 source network '10.201.0.0'
set policy access-list 100 rule 100 action 'permit'
set policy access-list 100 rule 100 destination any
set policy access-list 100 rule 100 source any
set policy route-map PUBOSPF rule 100 action 'deny'
set policy route-map PUBOSPF rule 100 match ip address access-list '100'
set policy route-map PUBOSPF rule 500 action 'permit'

```

Enable OSPF

Every router **must** have a unique router-id. The ‘reference-bandwidth’ is used because when OSPF was originally designed, the idea of a link faster than 1gbit was unheard of, and it does not scale correctly.

```

set protocols ospf area 0.0.0.0 authentication 'md5'
set protocols ospf area 0.0.0.0 network '10.254.60.0/24'
set protocols ospf auto-cost reference-bandwidth '10000'
set protocols ospf log-adjacency-changes
set protocols ospf parameters abr-type 'cisco'
set protocols ospf parameters router-id '10.254.60.2'
set protocols ospf route-map PUBOSPF

```

Test OSPF

When you have enabled OSPF on both routers, you should be able to see each other with the command `show ip ospf neighbour`. The state must be ‘Full’ or ‘2-Way’. If it is not, then there is a network connectivity issue between the hosts. This is often caused by NAT or MTU issues. You should not see any new routes (unless this is the second pass) in the output of `show ip route`

12.8.6 Advertise connected routes

As a reminder, only advertise routes that you are the default router for. This is why we are NOT announcing the 192.0.2.0/24 network, because if that was announced into OSPF, the other routers would try to connect to that network over a tunnel that connects to that network!

```
set protocols ospf access-list 150 export 'connected'
set protocols ospf redistribute connected
```

You should now be able to see the advertised network on the other host.

Duplicate configuration

At this point, you now need to create the X link between all four routers. Use a different /30 for each link.

Priorities

Set the cost on the secondary links to be 200. This means that they will not be used unless the primary links are down.

```
set protocols ospf interface wg01 cost '10'
set protocols ospf interface wg01 cost '200'
```

This will be visible in 'show ip route'.

12.8.7 BGP

BGP is an extremely complex network protocol. An example is provided here.

Note: Router id's must be unique.

router1

The redistribute ospf command is there purely as an example of how this can be expanded. In this walk-through, it will be filtered by BGPOUT rule 10000, as it is not 203.0.113.0/24.

```
set policy prefix-list BGPOUT description 'BGP Export List'
set policy prefix-list BGPOUT rule 10 action 'deny'
set policy prefix-list BGPOUT rule 10 description 'Do not advertise short masks'
set policy prefix-list BGPOUT rule 10 ge '25'
set policy prefix-list BGPOUT rule 10 prefix '0.0.0.0/0'
set policy prefix-list BGPOUT rule 100 action 'permit'
set policy prefix-list BGPOUT rule 100 description 'Our network'
set policy prefix-list BGPOUT rule 100 prefix '203.0.113.0/24'
set policy prefix-list BGPOUT rule 10000 action 'deny'
set policy prefix-list BGPOUT rule 10000 prefix '0.0.0.0/0'

set policy route-map BGPOUT description 'BGP Export Filter'
set policy route-map BGPOUT rule 10 action 'permit'
set policy route-map BGPOUT rule 10 match ip address prefix-list 'BGPOUT'
set policy route-map BGPOUT rule 10000 action 'deny'
set policy route-map BGPPREPENDOUT description 'BGP Export Filter'
set policy route-map BGPPREPENDOUT rule 10 action 'permit'
set policy route-map BGPPREPENDOUT rule 10 set as-path-prepend '65551 65551 65551'
```

(continues on next page)

(continued from previous page)

```
set policy route-map BGPPREPENDOUT rule 10 match ip address prefix-list 'BGPOUT'
set policy route-map BGPPREPENDOUT rule 10000 action 'deny'

set protocols bgp local-as 65551
set protocols bgp address-family ipv4-unicast network 192.0.2.0/24
set protocols bgp address-family ipv4-unicast redistribute connected metric '50'
set protocols bgp address-family ipv4-unicast redistribute ospf metric '50'
set protocols bgp neighbor 192.0.2.11 address-family ipv4-unicast route-map export
↪ 'BGPOUT'
set protocols bgp neighbor 192.0.2.11 address-family ipv4-unicast soft-
↪ reconfiguration inbound
set protocols bgp neighbor 192.0.2.11 remote-as '65550'
set protocols bgp neighbor 192.0.2.11 update-source '192.0.2.21'
set protocols bgp parameters router-id '192.0.2.21'
```

router2

This is identical, but you use the BGPPREPENDOUT route-map to advertise the route with a longer path.

12.9 WAN Load Balancer examples

12.9.1 Example 1: Distributing load evenly

The setup used in this example is shown in the following diagram:

Overview

- All traffic coming in through eth2 is balanced between eth0 and eth1 on the router.
- Pings will be sent to four targets for health testing (33.44.55.66, 44.55.66.77, 55.66.77.88 and 66.77.88.99).
- All outgoing packets are assigned the source address of the assigned interface (SNAT).
- eth0 is set to be removed from the load balancer's interface pool after 5 ping failures, eth1 will be removed after 4 ping failures.

Create static routes to ping targets

Create static routes through the two ISPs towards the ping targets and commit the changes:

```
set protocols static route 33.44.55.66/32 next-hop 11.22.33.1
set protocols static route 44.55.66.77/32 next-hop 11.22.33.1
set protocols static route 55.66.77.88/32 next-hop 22.33.44.1
set protocols static route 66.77.88.99/32 next-hop 22.33.44.1
```

Configure the load balancer

Configure the WAN load balancer with the parameters described above:

```
set load-balancing wan interface-health eth0 failure-count 5
set load-balancing wan interface-health eth0 nexthop 11.22.33.1
set load-balancing wan interface-health eth0 test 10 type ping
set load-balancing wan interface-health eth0 test 10 target 33.44.55.66
set load-balancing wan interface-health eth0 test 20 type ping
set load-balancing wan interface-health eth0 test 20 target 44.55.66.77
set load-balancing wan interface-health eth1 failure-count 4
set load-balancing wan interface-health eth1 nexthop 22.33.44.1
set load-balancing wan interface-health eth1 test 10 type ping
set load-balancing wan interface-health eth1 test 10 target 55.66.77.88
set load-balancing wan interface-health eth1 test 20 type ping
set load-balancing wan interface-health eth1 test 20 target 66.77.88.99
set load-balancing wan rule 10 inbound-interface eth2
set load-balancing wan rule 10 interface eth0
set load-balancing wan rule 10 interface eth1
```

12.9.2 Example 2: Failover based on interface weights

This example uses the failover mode.

Overview

In this example, eth0 is the primary interface and eth1 is the secondary interface. To provide simple failover functionality. If eth0 fails, eth1 takes over.

Create interface weight based configuration

The configuration steps are the same as in the previous example, except rule 10. So we keep the configuration, remove rule 10 and add a new rule for the failover mode:

```
delete load-balancing wan rule 10
set load-balancing wan rule 10 failover
set load-balancing wan rule 10 inbound-interface eth2
set load-balancing wan rule 10 interface eth0 weight 10
set load-balancing wan rule 10 interface eth1 weight 1
```

12.9.3 Example 3: Failover based on rule order

The previous example used the failover command to send traffic through eth1 if eth0 fails. In this example, failover functionality is provided by rule order.

Overview

Two rules will be created, the first rule directs traffic coming in from eth2 to eth0 and the second rule directs the traffic to eth1. If eth0 fails the first rule is bypassed and the second rule matches, directing traffic to eth1.

Create rule order based configuration

We keep the configuration from the previous example, delete rule 10 and create the two new rules as described:

```
delete load-balancing wan rule 10
set load-balancing wan rule 10 inbound-interface eth2
set load-balancing wan rule 10 interface eth0
set load-balancing wan rule 20 inbound-interface eth2
set load-balancing wan rule 20 interface eth1
```

12.9.4 Example 4: Failover based on rule order - priority traffic

A rule order for prioritizing traffic is useful in scenarios where the secondary link has a lower speed and should only carry high priority traffic. It is assumed for this example that eth1 is connected to a slower connection than eth0 and should prioritize VoIP traffic.

Overview

A rule order for prioritizing traffic is useful in scenarios where the secondary link has a lower speed and should only carry high priority traffic. It is assumed for this example that eth1 is connected to a slower connection than eth0 and should prioritize VoIP traffic.

Create rule order based configuration with low speed secondary link

We keep the configuration from the previous example, delete rule 20 and create a new rule as described:

```
delete load-balancing wan rule 20
set load-balancing wan rule 20 inbound-interface eth2
set load-balancing wan rule 20 interface eth1
set load-balancing wan rule 20 destination port sip
set load-balancing wan rule 20 protocol tcp
set protocols static route 0.0.0.0/0 next-hop 11.22.33.1
```

12.9.5 Example 5: Exclude traffic from load balancing

In this example two LAN interfaces exist in different subnets instead of one like in the previous examples:

Adding a rule for the second interface

Based on the previous example, another rule for traffic from the second interface eth3 can be added to the load balancer. However, traffic meant to flow between the LAN subnets will be sent to eth0 and eth1 as well. To prevent this, another rule is required. This rule excludes traffic between the local subnets from the load balancer. It also excludes locally-sources packets (required for web caching with load balancing). eth+ is used as an alias that refers to all ethernet interfaces:

```
set load-balancing wan rule 5 exclude
set load-balancing wan rule 5 inbound-interface eth+
set load-balancing wan rule 5 destination address 10.0.0.0/8
```

12.10 PPPoE IPv6 Basic Setup for Home Network

This document is to describe a basic setup using PPPoE with DHCPv6-PD + SLAAC to construct a typical home network. The user can follow the steps described here to quickly setup a working network and use this as a starting point to further configure or fine-tune other settings.

To achieve this, your ISP is required to support DHCPv6-PD. If you're not sure, please contact your ISP for more information.

12.10.1 Network Topology

12.10.2 Configurations

PPPoE Setup

```

set interfaces pppoe pppoe0 authentication password <YOUR PASSWORD>
set interfaces pppoe pppoe0 authentication user <YOUR USERNAME>
set interfaces pppoe pppoe0 service-name <YOUR SERVICENAME>
set interfaces pppoe pppoe0 source-interface 'eth0'
  
```

- Fill password and user with the credential provided by your ISP.
- service-name can be an arbitrary string.

DHCPv6-PD Setup

During address configuration, in addition to assigning an address to the WAN interface, ISP also provides a prefix to allow the router to configure addresses of LAN interface and other nodes connecting to LAN, which is called prefix delegation (PD).

```

set interfaces pppoe pppoe0 ipv6 address autoconf
set interfaces pppoe pppoe0 dhcpv6-options pd 0 interface eth1 address '100'
  
```

- Here we use the prefix to configure the address of eth1 (LAN) to form <prefix>::64, where 64 is hexadecimal of address 100.
- For home network users, most of time ISP only provides /64 prefix, hence there is no need to set SLA ID and prefix length. See [PPPoE](#) for more information.

Router Advertisement

We need to enable router advertisement for LAN network so that PC can receive the prefix and use SLAAC to configure the address automatically.

```
set service router-advert interface eth1 link-mtu '1492'
set service router-advert interface eth1 name-server <NAME SERVER>
set service router-advert interface eth1 prefix '::/64 valid-lifetime '172800'
```

- Set MTU in advertisement to 1492 because of PPPoE header overhead.
- Set DNS server address in the advertisement so that clients can obtain it by using RDNSS option. Most operating systems (Windows, Linux, Mac) should already support it.
- Here we set the prefix to `::/64` to indicate advertising any /64 prefix the LAN interface is assigned.
- Since some ISPs disconnects continuous connection for every 2~3 days, we set `valid-lifetime` to 2 days to allow PC for phasing out old address.

Basic Firewall

To have basic protection while keeping IPv6 network functional, we need to:

- Allow all established and related traffic for router and LAN
- Allow all icmpv6 packets for router and LAN
- Allow DHCPv6 packets for router

```
set firewall ipv6-name WAN_IN default-action 'drop'
set firewall ipv6-name WAN_IN rule 10 action 'accept'
set firewall ipv6-name WAN_IN rule 10 state established 'enable'
set firewall ipv6-name WAN_IN rule 10 state related 'enable'
set firewall ipv6-name WAN_IN rule 20 action 'accept'
set firewall ipv6-name WAN_IN rule 20 protocol 'icmpv6'
set firewall ipv6-name WAN_LOCAL default-action 'drop'
set firewall ipv6-name WAN_LOCAL rule 10 action 'accept'
set firewall ipv6-name WAN_LOCAL rule 10 state established 'enable'
set firewall ipv6-name WAN_LOCAL rule 10 state related 'enable'
set firewall ipv6-name WAN_LOCAL rule 20 action 'accept'
set firewall ipv6-name WAN_LOCAL rule 20 protocol 'icmpv6'
set firewall ipv6-name WAN_LOCAL rule 30 action 'accept'
set firewall ipv6-name WAN_LOCAL rule 30 destination port '546'
set firewall ipv6-name WAN_LOCAL rule 30 protocol 'udp'
set firewall ipv6-name WAN_LOCAL rule 30 source port '547'
set interfaces pppoe pppoe0 firewall in ipv6-name 'WAN_IN'
set interfaces pppoe pppoe0 firewall local ipv6-name 'WAN_LOCAL'
```

Note to allow the router to receive DHCPv6 response from ISP. We need to allow packets with source port 547 (server) and destination port 546 (client).

13.1 Build VyOS

13.1.1 Prerequisites

There are different ways you can build VyOS.

Building using a *Docker* container, although not the only way, is the easiest way as all dependencies are managed for you. However, you can also set up your own build machine and run a *Native Build*.

Note: Starting with VyOS 1.2 the release model of VyOS has changed. VyOS is now **free as in speech, but not as in beer**. This means that while VyOS is still an open source project, the release ISOs are no longer free and can only be obtained via subscription, or by contributing to the community.

The source code remains public and an ISO can be built using the process outlined in this chapter.

This will guide you through the process of building a VyOS ISO using *Docker*. This process has been tested on clean installs of Debian Jessie, Stretch, and Buster.

Docker

Installing *Docker* and prerequisites:

```
$ sudo apt-get update
$ sudo apt-get install -y apt-transport-https ca-certificates curl gnupg2 software-
→properties-common
$ curl -fsSL https://download.docker.com/linux/debian/gpg | sudo apt-key add -
$ sudo add-apt-repository "deb [arch=amd64] https://download.docker.com/linux/debian
→$(lsb_release -cs) stable"
$ sudo apt-get update
$ sudo apt-get install -y docker-ce
```

To be able to use [Docker](#) without `sudo`, the current non-root user must be added to the `docker` group by calling:
`sudo usermod -aG docker yourusername.`

Hint: Doing so grants privileges equivalent to the `root` user! It is recommended to remove the non-root user from the `docker` group after building the VyOS ISO. See also [Docker as non-root](#).

Note: The build process needs to be built on a local file system, building on SMB or NFS shares will result in the container failing to build properly! VirtualBox Drive Share is also not an option as block device operations are not implemented and the drive is always mounted as “nodev”

Build Container

The container can be built by hand or by fetching the pre-built one from DockerHub. Using the pre-built containers from the [VyOS DockerHub organisation](#) will ensure that the container is always up-to-date. A rebuild is triggered once the container changes (please note this will take 2-3 hours after pushing to the vyos-build repository).

Dockerhub

To manually download the container from DockerHub, run:

```
$ docker pull vyos/vyos-build:crux      # For VyOS 1.2
$ docker pull vyos/vyos-build:current  # For rolling release
```

Build from source

The container can also be built directly from source:

```
# For VyOS 1.2 (crux)
$ git clone -b crux --single-branch https://github.com/vyos/vyos-build
# For VyOS 1.3 (equuleus, current)
$ git clone -b current --single-branch https://github.com/vyos/vyos-build

$ cd vyos-build
$ docker build -t vyos/vyos-build:crux docker # For VyOS 1.2
$ docker build -t vyos/vyos-build:current docker      # For rolling release
```

Note: Since VyOS has switched to Debian (10) Buster in its `current` branch, you will require individual container for *current* and *crux* builds.

Tips and Tricks

You can create yourself some handy Bash aliases to always launch the latest - per release train (*current* or *crux*) - container. Add the following to your `.bash_aliases` file:

```
alias vybld='docker pull vyos/vyos-build:current && docker run --rm -it \
-v "$(pwd)":/vyos \
-v "$HOME/.gitconfig":/etc/gitconfig \
-v "$HOME/.bash_aliases":/home/vyos_bld/.bash_aliases \
-v "$HOME/.bashrc":/home/vyos_bld/.bashrc \
-w /vyos --privileged --sysctl net.ipv6.conf.lo.disable_ipv6=0 \
-e GOSU_UID=$(id -u) -e GOSU_GID=$(id -g) \
vyos/vyos-build:current bash'

alias vybld_crux='docker pull vyos/vyos-build:crux && docker run --rm -it \
-v "$(pwd)":/vyos \
-v "$HOME/.gitconfig":/etc/gitconfig \
-v "$HOME/.bash_aliases":/home/vyos_bld/.bash_aliases \
-v "$HOME/.bashrc":/home/vyos_bld/.bashrc \
-w /vyos --privileged --sysctl net.ipv6.conf.lo.disable_ipv6=0 \
-e GOSU_UID=$(id -u) -e GOSU_GID=$(id -g) \
vyos/vyos-build:crux bash'
```

Now you are prepared with two new aliases `vybld` and `vybld_crux` to spawn your development containers in your current working directory.

Native Build

To build VyOS natively you require a properly configured build host with the following Debian versions installed:

- Debian Jessie for VyOS 1.2 (crux)
- Debian Buster for VyOS 1.3 (equuleus, current) - aka the rolling release

To start, clone the repository to your local machine:

```
# For VyOS 1.2 (crux)
$ git clone -b crux --single-branch https://github.com/vyos/vyos-build

# For VyOS 1.3 (equuleus, current)
$ git clone -b current --single-branch https://github.com/vyos/vyos-build
```

For the packages required, you can refer to the `docker/Dockerfile` file in the [repository](#). The `./configure` script will also warn you if any dependencies are missing.

Once you have the required dependencies installed, you may proceed with the steps described in [Build ISO](#).

13.1.2 Build ISO

Now as you are aware of the prerequisites we can continue and build our own ISO from source. For this we have to fetch the latest source code from GitHub. Please note as this will differ for both *current* and *crux*.

```
# For VyOS 1.2 (crux)
$ git clone -b crux --single-branch https://github.com/vyos/vyos-build

# For VyOS 1.3 (equuleus, current)
$ git clone -b current --single-branch https://github.com/vyos/vyos-build
```

Now a fresh build of the VyOS ISO can begin. Change directory to the `vyos-build` directory and run:

```
$ cd vyos-build
# For VyOS 1.2 (crux)
$ docker run --rm -it --privileged -v $(pwd):/vyos -w /vyos vyos/vyos-build:crux bash

# For VyOS 1.3 (equuleus, current)
$ docker run --rm -it --privileged -v $(pwd):/vyos -w /vyos vyos/vyos-build:current_
↪bash
```

```
# For MacOS (crux, equuleus, sagitta)
$ git clone https://github.com/vyos/vyos-utils-misc
$ cd build-tools/macos-build

# For VyOS 1.2 (crux)
$ os=jessie64 branch=crux make build

# For VyOS 1.3 (equuleus)
$ os=buster64 branch=equuleus make build

# For VyOS 1.4 (sagitta)
$ os=buster64 branch=sagitta make build
```

Start the build:

```
vyos_bld@d4220bb519a0:/vyos# ./configure --architecture amd64 --build-by "j.
↪randomhacker@vyos.io"
vyos_bld@d4220bb519a0:/vyos# sudo make iso
```

When the build is successful, the resulting iso can be found inside the build directory as `live-image-[architecture].hybrid.iso`.

Good luck!

Hint: Building VyOS on Windows WSL2 with Docker integrated into WSL2 will work like a charm. No problems are known so far!

Customize

This ISO can be customized with the following list of configure options. The full and current list can be generated with `./configure --help`:

```
$ ./configure --help
usage: configure [-h] [--architecture ARCHITECTURE] [--build-by BUILD_BY]
               [--debian-mirror DEBIAN_MIRROR]
               [--debian-security-mirror DEBIAN_SECURITY_MIRROR]
               [--pbuilder-debian-mirror PBUILDER_DEBIAN_MIRROR]
               [--vyos-mirror VYOS_MIRROR] [--build-type BUILD_TYPE]
               [--version VERSION] [--build-comment BUILD_COMMENT] [--debug]
               [--custom-apt-entry CUSTOM_APT_ENTRY]
               [--custom-apt-key CUSTOM_APT_KEY]
               [--custom-package CUSTOM_PACKAGE]

optional arguments:
  -h, --help                show this help message and exit
  --architecture ARCHITECTURE
```

(continues on next page)

(continued from previous page)

```

                                Image target architecture (amd64 or i386 or armhf)
--build-by BUILD_BY           Builder identifier (e.g. jrandomhacker@example.net)
--debian-mirror DEBIAN_MIRROR
                                Debian repository mirror for ISO build
--debian-security-mirror DEBIAN_SECURITY_MIRROR
                                Debian security updates mirror
--pbuilder-debian-mirror PBUILDER_DEBIAN_MIRROR
                                Debian repository mirror for pbuilder env bootstrap
--vyos-mirror VYOS_MIRROR
                                VyOS package mirror
--build-type BUILD_TYPE
                                Build type, release or development
--version VERSION             Version number (release builds only)
--build-comment BUILD_COMMENT

                                Custom package to install from repositories

```

ISO Build Issues

There are (rare) situations where building an ISO image is not possible at all due to a broken package feed in the background. APT is not very good at reporting the root cause of the issue. Your ISO build will likely fail with a more or less similar looking error message:

```

The following packages have unmet dependencies:
  vyos-lx : Depends: accel-ppp but it is not installable
E: Unable to correct problems, you have held broken packages.
P: Begin unmounting filesystems...
P: Saving caches...
Reading package lists...
Building dependency tree...
Reading state information...
Del frr-pythontools 7.5-20210215-00-g8a5d3b7cd-0 [38.9 kB]
Del accel-ppp 1.12.0-95-g59f8e1b [475 kB]
Del frr 7.5-20210215-00-g8a5d3b7cd-0 [2671 kB]
Del frr-snmp 7.5-20210215-00-g8a5d3b7cd-0 [55.1 kB]
Del frr-rpki-rtrlib 7.5-20210215-00-g8a5d3b7cd-0 [37.3 kB]
make: *** [Makefile:30: iso] Error 1
(10:13) vyos_bld ece068908a5b:/vyos [current] #

```

To debug the build process and gain additional information of what could be the root cause you need to *chroot* into the build directory. This is explained in the following step by step procedure:

```
vyos_bld ece068908a5b:/vyos [current] # sudo chroot build/chroot /bin/bash
```

We now need to mount some required, volatile filesystems

```

(live)root@ece068908a5b:/# mount -t proc none /proc
(live)root@ece068908a5b:/# mount -t sysfs none /sys
(live)root@ece068908a5b:/# mount -t devtmpfs none /dev

```

We now are free to run any command we would like to use for debugging, e.g. re-installing the failed package after updating the repository.

```
(live)root@ece068908a5b:/# apt-get update; apt-get install vyos-lx
Get:1 file:/root/packages ./ InRelease
Ign:1 file:/root/packages ./ InRelease
Get:2 file:/root/packages ./ Release [1235 B]

↳ couldn't be accessed by user '_apt'. - pkgAcquire::Run (13: Permission denied)
Reading package lists... Done
Building dependency tree
Reading state information... Done
Some packages could not be installed. This may mean that you have
requested an impossible situation or if you are using the unstable
distribution that some required packages have not yet been created
or been moved out of Incoming.
The following information may help to resolve the situation:

The following packages have unmet dependencies:
 vyos-lx : Depends: accel-ppp but it is not installable
E: Unable to correct problems, you have held broken packages.
```

Now it's time to fix the package mirror and rerun the last step until the package installation succeeds again!

Linux Kernel

The Linux kernel used by VyOS is heavily tied to the ISO build process. The file `data/defaults.json` hosts a JSON definition of the kernel version used `kernel_version` and the `kernel_flavor` of the kernel which represents the kernel's `LOCAL_VERSION`. Both together form the kernel version variable in the system:

```
vyos@vyos:~$ uname -r
4.19.146-amd64-vyos
```

Other packages (e.g. `vyos-lx`) add dependencies to the ISO build procedure on e.g. the `wireguard-modules` package which itself adds a dependency on the kernel version used due to the module it ships. This may change (for WireGuard) in future kernel releases but as long as we have out-of-tree modules.

- WireGuard
- Accel-PPP
- Intel NIC drivers
- Inter QAT

Each of those modules holds a dependency on the kernel version and if you are lucky enough to receive an ISO build error which sounds like:

```
I: Create initramfs if it does not exist.
Extra argument '4.19.146-amd64-vyos'
Usage: update-initramfs {-c|-d|-u} [-k version] [-v] [-b directory]
Options:
  -k version      Specify kernel version or 'all'
  -c              Create a new initramfs
  -u              Update an existing initramfs
  -d              Remove an existing initramfs
  -b directory    Set alternate boot directory
  -v              Be verbose
See update-initramfs(8) for further details.
E: config/hooks/live/17-gen_initramfs.chroot failed (exit non-zero). You should check ↵
↵for errors.
```

The most obvious reasons could be:

- vyos-build repo is outdated, please `git pull` to update to the latest release kernel version from us.
- You have your own custom kernel *.deb packages in the *packages* folder but neglected to create all required out-of tree modules like Accel-PPP, WireGuard, Intel QAT, Intel NIC

Building The Kernel

The kernel build is quite easy, most of the required steps can be found in the `vyos-build/packages/linux-kernel/Jenkinsfile` but we will walk you through it.

Clone the kernel source to `vyos-build/packages/linux-kernel/`:

```
$ cd vyos-build/packages/linux-kernel/
$ git clone https://git.kernel.org/pub/scm/linux/kernel/git/stable/linux.git
```

Check out the required kernel version - see `vyos-build/data/defaults.json` file (example uses kernel 4.19.146):

```
$ cd vyos-build/packages/linux-kernel/linux
$ git checkout v4.19.146
Checking out files: 100% (61536/61536), done.
Note: checking out 'v4.19.146'.
```

You are in 'detached HEAD' state. You can look around, make experimental changes and commit them, and you can discard any commits you make in this state without impacting any branches by performing another checkout.

If you want to create a new branch to retain commits you create, you may do so (now or later) by using `-b` with the checkout command again. Example:

```
git checkout -b <new-branch-name>
```

```
HEAD is now at 015e94d0e37b Linux 4.19.146
```

Now we can use the helper script `build-kernel.sh` which does all the necessary voodoo by applying required patches from the `vyos-build/packages/linux-kernel/patches` folder, copying our kernel configuration `x86_64_vyos_defconfig` to the right location, and finally building the Debian packages.

Note: Building the kernel will take some time depending on the speed and quantity of your CPU/cores and disk

speed. Expect 20 minutes (or even longer) on lower end hardware.

```

dpkg-source --after-build .
dpkg-buildpackage: info: binary-only upload (no source included)

```

In the end you will be presented with the kernel binary packages which you can then use in your custom ISO build process, by placing all the *.deb files in the vyos-build/packages folder where they will be used automatically when building VyOS as documented above.

Firmware

If you upgrade your kernel or include new drivers you may need new firmware. Build a new vyos-linux-firmware package with the included helper scripts.

```

$ cd vyos-build/packages/linux-kernel
$ git clone https://git.kernel.org/pub/scm/linux/kernel/git/firmware/linux-firmware.
↳git
$ ./build-linux-firmware.sh

```

(continues on next page)

(continued from previous page)

```
$ cp vyos-linux-firmware_*.deb ../
```

This tries to automatically detect which blobs are needed based on which drivers were built. If it fails to find the correct files you can add them manually to `vyos-build/packages/linux-kernel/build-linux-firmware.sh`:

```
ADD_FW_FILES="iwlwifi* ath11k/QCA6390/*/*.bin"
```

Building Out-Of-Tree Modules

Building the kernel is one part, but now you also need to build the required out-of-tree modules so everything is lined up and the ABIs match. To do so, you can again take a look at `vyos-build/packages/linux-kernel/Jenkinsfile` to see all of the required modules and their selected versions. We will show you how to build all the current required modules.

WireGuard

First, clone the source code and check out the appropriate version by running:

```
$ cd vyos-build/packages/linux-kernel
$ git clone https://salsa.debian.org/debian/wireguard-linux-compat.git
$ cd wireguard-linux-compat
$ git checkout debian/1.0.20200712-1_bpo10+1
```

We again make use of a helper script and some patches to make the build work. Just run the following command:

```
$ cd vyos-build/packages/linux-kernel
$ ./build-wireguard-modules.sh
I: Apply WireGuard patch: /vyos/packages/linux-kernel/patches/wireguard-linux-compat/
↪0001-Debian-build-wireguard-modules-package.patch
patching file debian/control
patching file debian/rules
I: Build Debian WireGuard package
dpkg-buildpackage: info: source package wireguard-linux-compat

dpkg-buildpackage: info: source distribution buster-backports
dpkg-buildpackage: info: source changed by Unit 193 <unit193@debian.org>
dpkg-buildpackage: info: host architecture amd64
dpkg-source --before-build .
dpkg-source: info: using patch list from debian/patches/series
dpkg-source: info: applying 0001-Makefile-do-not-use-git-to-get-version-number.patch
dpkg-source: info: applying 0002-Avoid-trying-to-compile-on-debian-5.5-kernels-Closes.
↪patch
...

dpkg-genchanges: info: binary-only upload (no source code included)
dpkg-genchanges: info: debian/rules clean
dh clean
dh_clean
dpkg-source --after-build .
dpkg-source: info: unapplying 0002-Avoid-trying-to-compile-on-debian-5.5-kernels-
↪Closes.patch
```

(continues on next page)

(continued from previous page)

```
dpkg-source: info: unapplying 0001-Makefile-do-not-use-git-to-get-version-number.patch
dpkg-buildpackage: info: binary-only upload (no source included)
```

After compiling the packages you will find yourself the newly generated **.deb* binaries in `vyos-build/packages/linux-kernel` from which you can copy them to the `vyos-build/packages` folder for inclusion during the ISO build.

Accel-PPP

First, clone the source code and check out the appropriate version by running:

```
$ cd vyos-build/packages/linux-kernel
$ git clone https://github.com/accel-ppp/accel-ppp.git
```

We again make use of a helper script and some patches to make the build work. Just run the following command:

```
$ ./build-accel-ppp.sh
I: Build Accel-PPP Debian package
CMake Deprecation Warning at CMakeLists.txt:3 (cmake_policy):
  The OLD behavior for policy CMP0003 will be removed from a future version
  of CMake.

  The cmake-policies(7) manual explains that the OLD behaviors of all
  policies are deprecated and that a policy should be set to OLD only under
  specific short-term circumstances. Projects should be ported to the NEW
  behavior and not rely on setting a policy to OLD.

-- The C compiler identification is GNU 8.3.0

↳ deb generated.
```

After compiling the packages you will find yourself the newly generated **.deb* binaries in `vyos-build/packages/linux-kernel` from which you can copy them to the `vyos-build/packages` folder for inclusion during the ISO build.

Intel NIC

The Intel NIC drivers do not come from a Git repository, instead we just fetch the tarballs from our mirror and compile them.

Simply use our wrapper script to build all of the driver modules.

```
./build-intel-drivers.sh
% Total      % Received % Xferd  Average Speed   Time    Time       Time  Current
                        Dload  Upload    Total     Spent    Left     Speed
```

(continues on next page)

(continued from previous page)

```

I: Cleanup qat source

```

After compiling the packages you will find yourself the newly generated **.deb* binaries in `vyos-build/packages/linux-kernel` from which you can copy them to the `vyos-build/packages` folder for inclusion during the ISO build.

Packages

If you are brave enough to build yourself an ISO image containing any modified package from our GitHub organisation - this is the place to be.

Any “modified” package may refer to an altered version of e.g. `vyos-lx` package that you would like to test before filing a pull request on GitHub.

Building an ISO with any customized package is in no way different then building a regular (customized or not) ISO image. Simply place your modified `*.deb` package inside the `packages` folder within `vyos-build`. The build process will then pickup your custom package and integrate it into your ISO.

Troubleshooting

Debian APT is not very verbose when it comes to errors. If your ISO build breaks for whatever reason and you suspect it's a problem with APT dependencies or installation you can add this small patch which increases the APT verbosity during ISO build.

```
diff --git i/scripts/live-build-config w/scripts/live-build-config

Virtualization Platforms

QEMU

Run following command after building the ISO image.

```
$ make qemu
```

VMware

Run following command after building the QEMU image.

```
$ make vmware
```

13.1.3 Packages

VyOS itself comes with a bunch of packages that are specific to our system and thus cannot be found in any Debian mirror. Those packages can be found at the [VyOS GitHub project](#) in their source format can easily be compiled into a custom Debian (*.deb) package.

The easiest way to compile your package is with the above mentioned *Docker* container, it includes all required dependencies for all VyOS related packages.

Assume we want to build the vyos-lx package on our own and modify it to our needs. We first need to clone the repository from GitHub.

```
$ git clone https://github.com/vyos/vyos-lx
```

Build

Launch Docker container and build package

```
# For VyOS 1.3 (equuleus, current)
$ docker run --rm -it --privileged -v $(pwd):/vyos -w /vyos vyos/vyos-build:current_
↳ bash

# Change to source directory
$ cd vyos-lx

# Build DEB
$ dpkg-buildpackage -uc -us -tc -b
```

After a minute or two you will find the generated DEB packages next to the vyos-lx source directory:

```
# ls -al ../vyos-lx*.deb
-rw-r--r-- 1 vyos_bld vyos_bld 567420 Aug  3 12:01 ../vyos-lx_1.3dev0-1847-gb6dcb0a8_
↳ all.deb
-rw-r--r-- 1 vyos_bld vyos_bld  3808 Aug  3 12:01 ../vyos-lx-vmware_1.3dev0-1847-
↳ gb6dcb0a8_amd64.deb
```

Install

To take your newly created package on a test drive you can simply SCP it to a running VyOS instance and install the new *.deb package over the current running one.

Just install using the following commands:

```
vyos@vyos:~$ dpkg --install /tmp/vyos-lx_1.3dev0-1847-gb6dcb0a8_all.deb
(Reading database ... 58209 files and directories currently installed.)
Preparing to unpack .../vyos-lx_1.3dev0-1847-gb6dcb0a8_all.deb ...
Unpacking vyos-lx (1.3dev0-1847-gb6dcb0a8) over (1.3dev0-1847-gb6dcb0a8) ...
Setting up vyos-lx (1.3dev0-1847-gb6dcb0a8) ...
Processing triggers for rsyslog (8.1901.0-1) ...
```

You can also place the generated *.deb into your ISO build environment to include it in a custom iso, see [Linux Kernel](#) for more information.

Warning: Any packages in the packages directory will be added to the iso during build, replacing the upstream ones. Make sure you delete them (both the source directories and built deb packages) if you want to build an iso from purely upstream packages.

13.2 Development

All VyOS source code is hosted on GitHub under the VyOS organization which can be found here: <https://github.com/vyos>

Our code is split into several modules. VyOS is composed of multiple individual packages, some of them are forks of upstream packages and are periodically synced with upstream, so keeping the whole source under a single repository would be very inconvenient and slow. There is now an ongoing effort to consolidate all VyOS-specific framework/config packages into vyos-lx package, but the basic structure is going to stay the same, just with fewer and fewer packages while the base code is rewritten from Perl/BASH into Python using and XML based interface definition for the CLI.

The repository that contains all the ISO build scripts is: <https://github.com/vyos/vyos-build>

The README.md file will guide you to use the this top level repository.

13.2.1 Submit a Patch

Patches are always more than welcome. To have a clean and easy to maintain repository we have some guidelines when working with Git. A clean repository eases the automatic generation of a changelog file.

A good approach for writing commit messages is actually to have a look at the file(s) history by invoking `git log path/to/file.txt`.

Prepare patch/commit

In a big system, such as VyOS, that is comprised of multiple components, it's impossible to keep track of all the changes and bugs/feature requests in one's head. We use a bugtracker known as [Phabricator](#) for it ("issue tracker" would be a better term, but this one stuck).

The information is used in three ways:

- Keep track of the progress (what we've already done in this branch and what we still need to do).
- Prepare release notes for upcoming releases
- Help future maintainers of VyOS (it could be you!) to find out why certain things have been changed in the codebase or why certain features have been added

To make this approach work, every change must be associated with a task number (prefixed with **T**) and a component. If there is no bug report/feature request for the changes you are going to make, you have to create a [Phabricator](#) task first. Once there is an entry in [Phabricator](#), you should reference its id in your commit message, as shown below:

- `ddclient: T1030: auto create runtime directories`
- `Jenkins: add current Git commit ID to build description`

If there is no [Phabricator](#) reference in the commits of your pull request, we have to ask you to amend the commit message. Otherwise we will have to reject it.

Writing good commit messages

The format should be and is inspired by: <https://git-scm.com/book/ch5-2.html> It is also worth reading <https://chris.beams.io/posts/git-commit/>

- A single, short, summary of the commit (recommended 50 characters or less, not exceeding 80 characters) containing a prefix of the changed component and the corresponding [Phabricator](#) reference e.g. `snmp: T1111:` or `ethernet: T2222:` - multiple components could be concatenated as in `snmp: ethernet: T3333`
- In some contexts, the first line is treated as the subject of an email and the rest of the text as the body. The blank line separating the summary from the body is critical (unless you omit the body entirely); tools like `rebase` can get confused if you run the two together.
- Followed by a message which describes all the details like:
 - What/why/how something has been changed, makes everyone's life easier when working with `git bisect`
 - All text of the commit message should be wrapped at 72 characters if possible which makes reading commit logs easier with `git log` on a standard terminal (which happens to be 80x25)
 - If applicable a reference to a previous commit should be made linking those commits nicely when browsing the history: After commit `abcd12ef` ("snmp: this is a headline") a Python `import` statement is missing, throwing the following exception: `ABCDEF`
- Always use the `-x` option to the `git cherry-pick` command when back or forward porting an individual commit. This automatically appends the line: `(cherry picked from commit <ID>)` to the original authors commit message making it easier when bisecting problems.
- Every change set must be consistent (self containing)! Do not fix multiple bugs in a single commit. If you already worked on multiple fixes in the same file use `git add -patch` to only add the parts related to the one issue into your upcoming commit.

Limits:

- We only accept bugfixes in packages other than <https://github.com/vyos/vyos-1x> as no new functionality should use the old style templates (`node.def` and Perl/BASH code. Use the new style XML/Python interface instead.

Please submit your patches using the well-known GitHub pull-request against our repositories found in the VyOS GitHub organisation at <https://github.com/vyos>

Determine source package

Suppose you want to make a change in the `webproxy` script but yet you do not know which of the many VyOS packages ship this file. You can determine the VyOS package name in question by using Debian's `dpkg -S` command of your running VyOS installation.

```
vyos@vyos:~$ dpkg -S /opt/vyatta/sbin/vyatta-update-webproxy.pl
vyatta-webproxy: /opt/vyatta/sbin/vyatta-update-webproxy.pl
```

This means the file in question (`/opt/vyatta/sbin/vyatta-update-webproxy.pl`) is located in the `vyatta-webproxy` package which can be found here: <https://github.com/vyos/vyatta-webproxy>

Fork Repository and submit Patch

Forking the repository and submitting a GitHub pull-request is the preferred way of submitting your changes to VyOS. You can fork any VyOS repository to your very own GitHub account by just appending `/fork` to any repository's

URL on GitHub. To e.g. fork the `vyos-1x` repository, open the following URL in your favourite browser: <https://github.com/vyos/vyos-1x/fork>

You then can proceed with cloning your fork or add a new remote to your local repository:

- Clone: `git clone https://github.com/<user>/vyos-1x.git`
- Fork: `git remote add myfork https://github.com/<user>/vyos-1x.git`

In order to record you as the author of the fix please identify yourself to Git by setting up your name and email. This can be done local for this one and only repository `git config` or globally using `git config --global`.

```
git config --global user.name "J. Random Hacker"
git config --global user.email "jrhacker@example.net"
```

Make your changes and save them. Do the following for all changes files to record them in your created Git commit:

- Add file to Git index using `git add myfile`, or for a whole directory: `git add somedir/*`
- Commit the changes by calling `git commit`. Please use a meaningful commit headline (read above) and don't forget to reference the [Phabricator ID](#).
- Submit the patch `git push` and create the GitHub pull-request.

Attach patch to Phabricator task

Follow the above steps on how to “Fork repository to submit a Patch”. Instead of uploading “pushing” your changes to GitHub you can export the patches/ commits and send it to maintainers@vyos.net or attach it directly to the bug (preferred over email)

- Export last commit to patch file: `git format-patch` or export the last two commits into its appropriate patch files: `git format-patch -2`

13.2.2 Coding Guidelines

Like any other project we have some small guidelines about our source code, too. The rules we have are not there to punish you - the rules are in place to help us all. By having a consistent coding style it becomes very easy for new and also longtime contributors to navigate through the sources and all the implied logic of any one source file..

Python 3 **shall** be used. How long can we keep Python 2 alive anyway? No considerations for Python 2 compatibility **should** be taken at any time.

Formatting

- Python: Tabs **shall not** be used. Every indentation level should be 4 spaces
- XML: Tabs **shall not** be used. Every indentation level should be 2 spaces

Note: There are extensions to e.g. VIM (xmllint) which will help you to get your indention levels correct. Add to following to your `.vimrc` file: `au FileType xml setlocal equalprg=xmllint\ --format\ --recover\ -\ 2>/dev/null` now you can call the linter using `gg=G` in command mode.

Text generation

Template processor **should** be used for generating config files. Built-in string formatting **may** be used for simple line-oriented formats where every line is self-contained, such as iptables rules. Template processor **must** be used for structured, multi-line formats such as those used by ISC DHCPd.

The default template processor for VyOS code is Jinja2.

Summary

When modifying the source code, remember these rules of the legacy elimination campaign:

- No new features in Perl
- No old style command definitions
- No code incompatible with Python3

13.2.3 Python

The switch to the Python programming language for new code is not merely a change of the language, but a chance to rethink and improve the programming approach.

Let's face it: VyOS is full of spaghetti code where logic for reading the VyOS config, generating daemon configs, and restarting processes is all mixed up.

Python (or any other language, for that matter) does not provide automatic protection from bad design, so we need to also devise design guidelines and follow them to keep the system extensible and maintainable.

But we are here to assist you and want to guide you through how you can become a good VyOS contributor. The rules we have are not there to punish you - the rules are in place to help us all. What does it mean? By having a consistent coding style it becomes very easy for new contributors and also longtime contributors to navigate through the sources and all the implied logic of the spaghetti code.

Please use the following template as good starting point when developing new modules or even rewrite a whole bunch of code in the new style XML/Python interface.

Configuration Script Structure and Behaviour

Your configuration script or operation mode script which is also written in Python3 should have a line break on 80 characters. This seems to be a bit odd nowadays but as some people also work remotely or program using vi(m) this is a fair good standard which I hope we can rely on.

In addition this also helps when browsing the GitHub codebase on a mobile device if you happen to be a crazy scientist.

```
#!/usr/bin/env python3

import sys

from vyos.config import Config
from vyos import ConfigError

def get_config():
    if config:
        conf = config
    else:
        conf = Config()

    # Base path to CLI nodes
    base = ['...', '...']
    # Convert the VyOS config to an abstract internal representation
    config_data = conf.get_config_dict(base, key_mangling=('-', '_'), get_first_
↪key=True)
    return config_data

def verify(config):
    # Verify that configuration is valid
    if invalid:
        raise ConfigError("Descriptive message")
    return True

def generate(config):
    # Generate daemon configs
    pass

def apply(config):
    # Apply the generated configs to the live system
    pass

try:
    c = get_config()
    verify(c)
    generate(c)
    apply(c)
except ConfigError as e:
    print(e)
    sys.exit(1)

```

The `get_config()` function must convert the VyOS config to an abstract, internal representation. No other function is allowed to call the `vyos.config.Config` object method directly. The rationale for it is that when config reads are mixed with other logic, it's very hard to change the config syntax since you need to weed out every occurrence of the old syntax. If syntax-specific code is confined to a single function, the rest of the code can be left untouched as long as the internal representation remains compatible.

Another advantage is testability of the code. Mocking the entire config subsystem is hard, while constructing an internal representation by hand is way simpler.

The `verify()` function takes your internal representation of the config and checks if it's valid, otherwise it must raise `ConfigError` with an error message that describes the problem and possibly suggests how to fix it. It must

not make any changes to the system. The rationale for it is again testability and, in the future when the config backend is ready and every script is rewritten in this fashion, ability to execute commit dry run (“commit test” like in JunOS) and abort commit before making any changes to the system if an error is found in any component.

The `generate()` function generates config files for system components.

The `apply()` function applies the generated configuration to the live system. It should use non-disruptive reload whenever possible. It may execute disruptive operations such as daemon process restart if a particular component does not support non-disruptive reload, or when the expected service degradation is minimal (for example, in case of auxiliary services such as LLDPd). In case of high impact services such as VPN daemon and routing protocols, when non-disruptive reload is supported for some but not all types of configuration changes, scripts authors should make effort to determine if a configuration change can be done in a non-disruptive way and only resort to disruptive restart if it cannot be avoided.

Unless absolutely necessary, configuration scripts should not modify the active configuration of system components directly. Whenever at all possible, scripts should generate a configuration file or files that can be applied with a single command such as reloading a service through `systemd init`. Inserting statements one by one is particularly discouraged, for example, when configuring netfilter rules, saving them to a file and loading it with `iptables-restore` should always be preferred to executing `iptables` directly.

The `apply()` and `generate()` functions may raise `ConfigError` if, for example, the daemon failed to start with the updated config. It shouldn’t be a substitute for proper config checking in the `verify()` function. All reasonable effort should be made to verify that generated configuration is valid and will be accepted by the daemon, including, when necessary, cross-checks with other VyOS configuration subtrees.

Exceptions, including `VyOSError` (which is raised by `vyos.config.Config` on improper config operations, such as trying to use `list_nodes()` on a non-tag node) should not be silenced or caught and re-raised as config error. Sure this will not look pretty on user’s screen, but it will make way better bug reports, and help users (and most VyOS users are IT professionals) do their own debugging as well.

For easy orientation we suggest you take a look on the `ntp.py` or `interfaces-bonding.py` (for tag nodes) implementation. Both files can be found in the `vyos-lx` repository.

13.2.4 XML (used for CLI definitions)

The bash (or better vbash) completion in VyOS is defined in *templates*. Templates are text files (called `node.def`) stored in a directory tree. The directory names define the command names, and template files define the command behaviour. Before VyOS 1.2 (crux) this files were created by hand. After a complex redesign [process](#) the new style template are automatically generated from a XML input file.

XML interface definitions for VyOS come with a RelaxNG schema and are located in the `vyos-lx` module. This schema is a slightly modified schema from [VyConf](#) alias VyOS 2.0 So VyOS 1.2.x interface definitions will be reusable in Nextgen VyOS Versions with very minimal changes.

The great thing about schemas is not only that people can know the complete grammar for certain, but also that it can be automatically verified. The `scripts/build-command-templates` script that converts the XML definitions to old style templates also verifies them against the schema, so a bad definition will cause the package build to fail. I do agree that the format is verbose, but there is no other format now that would allow this. Besides, a specialized XML editor can alleviate the issue with verbosity.

Example:

```
<?xml version="1.0"?>
<!-- Cron configuration -->
<interfaceDefinition>
  <node name="system">
    <children>
```

(continues on next page)

(continued from previous page)

```

<node name="task-scheduler">
  <properties>
    <help>Task scheduler settings</help>
  </properties>
  <children>
    <tagNode name="task" owner="{vyos_conf_scripts_dir}/task_scheduler.py">
      <properties>
        <help>Scheduled task</help>
        <valueHelp>
          <format>&lt;string&gt;</format>
          <description>Task name</description>
        </valueHelp>
        <priority>999</priority>
      </properties>
      <children>
        <leafNode name="crontab-spec">
          <properties>
            <help>UNIX crontab time specification string</help>
          </properties>
        </leafNode>
        <leafNode name="interval">
          <properties>
            <help>Execution interval</help>
            <valueHelp>
              <format>&lt;minutes&gt;</format>
              <description>Execution interval in minutes</description>
            </valueHelp>
            <valueHelp>
              <format>&lt;minutes&gt;m</format>
              <description>Execution interval in minutes</description>
            </valueHelp>
            <valueHelp>
              <format>&lt;hours&gt;h</format>
              <description>Execution interval in hours</description>
            </valueHelp>
            <valueHelp>
              <format>&lt;days&gt;d</format>
              <description>Execution interval in days</description>
            </valueHelp>
            <constraint>
              <regex>[1-9] ([0-9]*) ([mhd] {0,1}) </regex>
            </constraint>
          </properties>
        </leafNode>
        <node name="executable">
          <properties>
            <help>Executable path and arguments</help>
          </properties>
          <children>
            <leafNode name="path">
              <properties>
                <help>Path to executable</help>
              </properties>
            </leafNode>
            <leafNode name="arguments">
              <properties>
                <help>Arguments passed to the executable</help>
              </properties>
            </leafNode>
          </children>
        </node>
      </children>
    </tagNode>
  </children>
</node>

```

(continues on next page)

(continued from previous page)

```

        </properties>
      </leafNode>
    </children>
  </node>
</children>
</tagNode>
</children>
</node>
</children>
</node>
</interfaceDefinition>

```

Command definitions are purely declarative, and cannot contain any logic. All logic for generating config files for target applications, restarting services and so on is implemented in configuration scripts instead.

GNU Preprocessor

XML interface definition files use the *xml.in* file extension which was implemented in [T1843](#). XML interface definitions tend to have a lot of duplicated code in areas such as:

- VIF (incl. VIF-S/VIF-C)
- Address
- Description
- Enabled/Disabled

Instead of supplying all those XML nodes multiple times there are now include files with predefined features. Brief overview:

- [IPv4, IPv6 and DHCP\(v6\)](#) address assignment
- [IPv4, IPv6](#) address assignment
- [VLAN \(VIF\)](#) definition
- [MAC address](#) assignment

All interface definition XML input files (.in suffix) will be sent to the GCC preprocess and the output is stored in the *build/interface-definitions* folder. The previously mentioned *scripts/build-command-templates* script operates on the *build/interface-definitions* folder to generate all required CLI nodes.

```

$ make interface_definitions
install -d -m 0755 build/interface-definitions
install -d -m 0755 build/op-mode-definitions
Generating build/interface-definitions/intel_qat.xml from interface-definitions/intel_
↳ qat.xml.in
Generating build/interface-definitions/interfaces-bonding.xml from interface-
↳ definitions/interfaces-bonding.xml.in
Generating build/interface-definitions/cron.xml from interface-definitions/cron.xml.in
Generating build/interface-definitions/pppoe-server.xml from interface-definitions/
↳ pppoe-server.xml.in
Generating build/interface-definitions/mdns-repeater.xml from interface-definitions/
↳ mdns-repeater.xml.in
Generating build/interface-definitions/tftp-server.xml from interface-definitions/
↳ tftp-server.xml.in
[...]
```

Guidelines

Use of numbers

Use of numbers in command names **should** be avoided unless a number is a part of a protocol name or similar. Thus, protocols `ospfv3` is perfectly fine, but something like `server-1` is questionable at best.

Help String

To ensure uniform look and feel, and improve readability, we should follow a set of guidelines consistently.

Capitalization and punctuation

The first word of every help string **must** be capitalized. There **must not** be a period at the end of help strings.

Rationale: this seems to be the unwritten standard in network device CLIs, and a good aesthetic compromise.

Examples:

- Good: “Frobnication algorithm”
- Bad: “frobnication algorithm”
- Bad: “Frobnication algorithm.”
- Horrible: “frobnication algorithm.”

Use of abbreviations and acronyms

Abbreviations and acronyms **must** be capitalized.

Examples:

- Good: “TCP connection timeout”
- Bad: “tcp connection timeout”
- Horrible: “Tcp connection timeout”

Acronyms also **must** be capitalized to visually distinguish them from normal words:

Examples:

- Good: RADIUS (as in remote authentication for dial-in user services)
- Bad: radius (unless it’s about the distance between a center of a circle and any of its points)

Some abbreviations are traditionally written in mixed case. Generally, if it contains words “over” or “version”, the letter **should** be lowercase. If there’s an accepted spelling (especially if defined by an RFC or another standard), it **must** be followed.

Examples:

- Good: PPPoE, IPsec
- Bad: PPPOE, IPSEC
- Bad: pppoe, ipsec

Use of verbs

Verbs **should** be avoided. If a verb can be omitted, omit it.

Examples:

- Good: “TCP connection timeout”
- Bad: “Set TCP connection timeout”

If a verb is essential, keep it. For example, in the help text of `set system ipv6 disable-forwarding`, “Disable IPv6 forwarding on all interfaces” is a perfectly justified wording.

Prefer infinitives

Verbs, when they are necessary, **should** be in their infinitive form.

Examples:

- Good: “Disable IPv6 forwarding”
- Bad: “Disables IPv6 forwarding”

Migrating old CLI

Old concept/syntax	New syntax	Notes
mynode/node.def	<node name="mynode"> </node>	Leaf nodes (nodes with values) use <leafNode> tag instead
mynode/node.tag , tag:	<tagNode name="mynode"> </node>	
help: My node	<properties> <help>My node</help>	
val_help: <format>; some string	<properties> <value- Help> <format> format </format> <description> some string </descrip- tion>	Do not add angle brackets around the format, they will be inserted automatically
syntax:expression: pattern	<properties> <constraint> <regex> ...	<constraintErrorMessage> will be displayed on failure
syntax:expression: \$VAR(@) in "foo", "bar", "baz"	None	Use regex
syntax:expression: exec ...	<properties> <constraint> <validator> <name ="foo" argument="bar">	"\${vyos_libexecdir}/validators/foo bar \$VAR(@)" will be executed, <constraintErrorMessage> will be displayed on failure
syntax:expression: (arith- metic expression)	None	External arithmetic validator may be added if there's demand, complex validation is better left to commit-time scripts
priority: 999	<properties> <prior- ity>999</priority>	Please leave a comment explaining why the priority was chosen (e.g. "after interfaces are configured")
multi:	<properties> <multi/>	Only applicable to leaf nodes
allowed: echo foo bar	<properties> <comple- tionHelp> <list> foo bar </list>	
allowed: cli-shell-api listNodes vpn ipsec esp-group	<properties> <comple- tionHelp> <path> vpn ipsec esp-group </path> ...	
allowed: /path/to/script	<properties> <com- pletionHelp> <script> </script> /path/to/script </script> ...	
default:	None	Move default values to scripts
commit:expression:	None	All commit time checks should be in the verify() function of the script
begin:/create:/delete:	None	All logic should be in the scripts

13.2.5 Continuous Integration

VyOS makes use of [Jenkins](https://ci.vyos.net) as our Continuous Integration (CI) service. Our CI server is publicly accessible here: <https://ci.vyos.net>. You can get a brief overview of all required components shipped in a VyOS ISO.

To build our modules we utilize a CI/CD Pipeline script. Each and every VyOS component comes with its own `Jenkinsfile` which is (more or less) a copy. The Pipeline utilizes the Docker container from the [Build ISO](#) section

- but instead of building it from source on every run, we rather always fetch a fresh copy (if needed) from [Dockerhub](#). Each module is build on demand if a new commit on the branch in question is found. After a successful run the resulting Debian Package(s) will be deployed to our Debian repository which is used during build time. It is located here: <http://dev.packages.vyos.net/repositories/>.

13.3 Documentation

VyOS documentation is written in reStructuredText and generated to Read the Docs pages with Sphinx, as per the Python tradition, as well as PDF files for offline use through LaTeX.

We welcome all sorts of contributions to the documentation. Not just new additions but also corrections to existing documentation.

13.3.1 Guidelines

There are a few things to keep in mind when contributing to the documentation, for the sake of consistency and readability.

Take a look at the [Documentation](#) page for an intricate explanation of the documentation process.

The following is a quick summary of the rules:

- Use American English at all times. It's always a good idea to run your text through a grammar and spell checker, such as [Grammarly](#).
- Don't forget to update `index.rst` when adding a new node.
- Try not to exceed 80 characters per line, but don't break URLs over this.
- Properly quote commands, filenames and brief code snippets with double backticks.
- Use literal blocks for longer snippets.
- Leave a newline before and after a header.
- Indent with two spaces.
- When in doubt, follow the style of existing documentation.

And finally, remember that the reStructuredText files aren't exclusively for generating HTML and PDF. They should be human-readable and easily perused from a console.

13.3.2 Building

The source is kept in the Git repository <https://github.com/vyos/vyos-documentation>

You can follow the instructions in the README to build and test your changes.

You can either install Sphinx (and TeX Live for PDF output) and build the documentation locally, or use the [Dockerfile](#) to build it in a container.

13.4 Issues/Feature requests

13.4.1 Bug Report/Issue

Issues or bugs are found in any software project. VyOS is not an exception.

All issues should be reported to the developers. This lets the developers know what is not working properly. Without this sort of feedback every developer will believe that everything is working correctly.

I have found a bug, what should I do?

When you believe you have found a bug, it is always a good idea to verify the issue prior to opening a bug request.

- Consult the [documentation](#) to ensure that you have configured your system correctly
- Get community support via [Slack](#) or our [Forum](#)

Ensure the problem is reproducible

When you are able to verify that it is actually a bug, spend some time to document how to reproduce the issue. This documentation can be invaluable.

When you wish to have a developer fix a bug that you found, helping them reproduce the issue is beneficial to everyone. Be sure to include information about the hardware you are using, commands that you were running, any other activities that you may have been doing at the time. This additional information can be very useful.

- What were you attempting to achieve?
- What was the configuration prior to the change?
- What commands did you use? Use e.g. `run show configuration commands`

Include output

The output you get when you find a bug can provide lots of information. If you get an error message on the screen, copy it exactly. Having the exact message can provide detail that the developers can use. Like wise if you have any log messages that also are from the time of the issue, include those. They may also contain information that is helpful for the development team.

Report a Bug

In order to open up a bug-report/feature request you need to create yourself an account on VyOS [Phabricator](#). On the left side of the specific project (VyOS 1.2 or VyOS 1.3) you will find quick-links for opening a bug-report/feature request.

- Provide as much information as you can
- Which version of VyOS are you using? `run show version`
- How can we reproduce this Bug?

13.4.2 Feature Request

You have an idea of how to make VyOS better or you are in need of a specific feature which all users of VyOS would benefit from? To send a feature request please search [Phabricator](#) if there is already a request pending. You can enhance it or if you don't find one, create a new one by use the quick link in the left side under the specific project.

13.5 Upstream packages

Many base system packages are pulled straight from Debian's main and contrib repositories, but there are exceptions.

This chapter lists those exceptions and gives you a brief overview what we have done on those packages. If you only want to build yourself a fresh ISO you can completely skip this chapter. It may become interesting once you have a VyOS deep dive.

13.5.1 vyos-netplug

Due to issues in the upstream version that sometimes set interfaces down, a modified version is used.

The source is located at <https://github.com/vyos/vyos-netplug>

In the future, we may switch to using systemd infrastructure instead. Building it doesn't require a special procedure.

13.5.2 keepalived

Keepalived normally isn't updated to newer feature releases between Debian versions, so we are building it from source.

Debian does keep their package in git, but it's upstream tarball imported into git without its original commit history. To be able to merge new tags in, we keep a fork of the upstream repository with packaging files imported from Debian at <https://github.com/vyos/keepalived-upstream>

13.5.3 strongswan

Our StrongSWAN build differs from the upstream:

- strongswan-nm package build is disabled since we don't use NetworkManager
- Patches for DMVPN are merged in

The source is at <https://github.com/vyos/vyos-strongswan>

DMVPN patches are added by this commit: <https://github.com/vyos/vyos-strongswan/commit/1cf12b0f2f921bfc51affa3b81226>

Our op mode scripts use the python-vici module, which is not included in Debian's build, and isn't quite easy to integrate in that build. For this reason we debianize that module by hand now, using this procedure:

0. Install <https://pypi.org/project/stdeb/>
1. `cd vyos-strongswan`
2. `./configure --enable-python-eggs`
3. `cd src/libcharon/plugins/vici/python`
4. `make`

5. `python3 setup.py --command-packages=stdeb.command bdist_deb`

The package ends up in `deb_dist` dir.

13.5.4 mdns-repeater

This package doesn't exist in Debian. A debianized fork is kept at <https://github.com/vyos/mdns-repeater>

No special build procedure is required.

13.5.5 udp-broadcast-relay

This package doesn't exist in Debian. A debianized fork is kept at <https://github.com/vyos/udp-broadcast-relay>

No special build procedure is required.

13.5.6 hvinfo

A fork with packaging changes for VyOS is kept at <https://github.com/vyos/hvinfo>

The original repo is at <https://github.com/dmbaturin/hvinfo>

It's an Ada program and requires GNAT and gprbuild for building, dependencies are properly specified so just follow `debuild`'s suggestions.

There are two flags available to aid in debugging configuration scripts. Since configuration loading issues will manifest during boot, the flags are passed as kernel boot parameters.

14.1 ISO image build

When having trouble compiling your own ISO image or debugging Jenkins issues you can follow the steps at *ISO Build Issues*.

14.2 System Startup

The system startup can be debugged (like loading in the configuration file from `/config/config.boot`). This can be achieved by extending the Kernel command-line in the bootloader.

14.2.1 Kernel

- `vyos-debug` - Adding the parameter to the linux boot line will produce timing results for the execution of scripts during commit. If one is seeing an unexpected delay during manual or boot commit, this may be useful in identifying bottlenecks. The internal flag is `VYOS_DEBUG`, and is found in `vyatta-cfg`. Output is directed to `/var/log/vyatta/cfg-stdout.log`.
- `vyos-config-debug` - During development, coding errors can lead to a commit failure on boot, possibly resulting in a failed initialization of the CLI. In this circumstance, the kernel boot parameter `vyos-config-debug` will ensure access to the system as user `vyos`, and will log a Python stack trace to the file `/tmp/boot-config-trace`. File `boot-config-trace` will generate only if config loaded with a failure status.

14.3 Live System

A number of flags can be set up to change the behaviour of VyOS at runtime. These flags can be toggled using either environment variables or creating files.

For each feature, a file called `vyos.feature.debug` can be created to toggle the feature on. If a parameter is required it can be placed inside the file as its first line.

The file can be placed in `/tmp` for one time debugging (as the file will be removed on reboot) or placed in `/config` to stay permanently.

For example, `/tmp/vyos.ifconfig.debug` can be created to enable interface debugging.

It is also possible to set up the debugging using environment variables. In that case, the name will be (in uppercase) `VYOS_FEATURE_DEBUG`.

For example running, `export VYOS_IFCONFIG_DEBUG=""` on your `vbash`, will have the same effect as `touch /tmp/vyos.ifconfig.debug`.

- `ifconfig` - Once set, all commands used, and their responses received from the OS, will be presented on the screen for inspection.
- `command` - Once set, all commands used, and their responses received from the OS, will be presented on the screen for inspection.
- `developer` - Should a command fail, instead of printing a message to the user explaining how to report issues, the python interpreter will start a PBD post-mortem session to allow the developer to debug the issue. As the debugger will wait from input from the developer, it has the capacity to prevent a router to boot and therefore should only be permanently set up on production if you are ready to see the OS fail to boot.
- `log` - In some rare cases, it may be useful to see what the OS is doing, including during boot. This option sends all commands used by VyOS to a file. The default file is `/tmp/full-log` but it can be changed.

Note: In order to retrieve the debug output on the command-line you need to disable `vyos-configd` in addition. This can be run either one-time by calling `sudo systemctl stop vyos-configd` or make this reboot-safe by calling `sudo systemctl disable vyos-configd`.

14.3.1 FRR

Recent versions use the `vyos.frr` framework. The Python class is located inside our `vyos-1x:python/vyos/frr.py`. It comes with an embedded debugging/ (print style) debugger as `vyos.ifconfig` does.

To enable debugging just run: `$ touch /tmp/vyos.frr.debug`

14.3.2 Debugging Python Code with PDB

Sometimes it might be useful to debug Python code interactively on the live system rather than a IDE. This can be achieved using `pdb`.

Let us assume you want to debug a Python script that is called by an op-mode command. After you found the script by looking up the op-mode-definitions you can edit the script in the live system using e.g. `vi: vi /usr/libexec/vyos/op_mode/show_xyz.py`

Insert the following statement right before the section where you want to investigate a problem (e.g. a statement you see in a backtrace): `import pdb; pdb.set_trace()` Optionally you can surrounded this statement by an `if` which only triggers under the condition you are interested in.

Once you run `show xyz` and your condition is triggered you should be dropped into the python debugger:

```
> /usr/libexec/vyos/op_mode/show_nat_translations.py(109)process()
-> rule_type = rule.get('type', '')
(Pdb)
```

You can type `help` to get an overview of the available commands, and `help` command to get more information on each command.

Useful commands are:

- examine variables using `pp(var)`
- continue execution using `cont`
- get a backtrace using `bt`

14.3.3 Config Migration Scripts

When writing a new configuration migrator it may happen that you see an error when you try to invoke it manually on a development system. This error will look like:

```
vyos@vyos:~$ /opt/vyatta/etc/config-migrate/migrate/ssh/0-to-1 /tmp/config.boot
Traceback (most recent call last):
  File "/opt/vyatta/etc/config-migrate/migrate/ssh/0-to-1", line 31, in <module>
    config = ConfigTree(config_file)
  File "/usr/lib/python3/dist-packages/vyos/configtree.py", line 134, in __init__
    raise ValueError("Failed to parse config: {0}".format(msg))
ValueError: Failed to parse config: Syntax error on line 240, character 1: Invalid_
↪syntax.
```

The reason is that the configuration migration backend is rewritten and uses a new form of “magic string” which is applied on demand when real config migration is run on boot. When running individual migrators for testing, you need to convert the “magic string” on your own by:

```
vyos@vyos:~$ /usr/libexec/vyos/run-config-migration.py --virtual --set-vintage vyos /
↪tmp/config.boot
```

14.3.4 Configuration Error on System Boot

Being brave and running the latest rolling releases will sometimes trigger bugs due to corner cases we missed in our design. Those bugs should be filed via [Phabricator](#) but you can help us to narrow down the issue. Login to your VyOS system and change into configuration mode by typing `configure`. Now re-load your boot configuration by simply typing `load` followed by `return`.

You should now see a Python backtrace which will help us to handle the issue, please attach it to the [Phabricator](#) task.

14.3.5 Boot Timing

During the migration and extensive rewrite of functionality from Perl into Python a significant increase in the overall system boot time was noticed. The system boot time can be analysed and a graph can be generated in the end which shows in detail who called whom during the system startup phase.

This is done by utilizing the `systemd-bootchart` package which is now installed by default on the VyOS 1.3 (equuleus) branch. The configuration is also versioned so we get comparable results. `systemd-bootchart` is configured using this file: `bootchart.conf`

To enable boot time graphing change the Kernel commandline and add the following string: `init=/usr/lib/systemd/systemd-bootchart`

This can also be done permanently by changing `/boot/grub/grub.cfg`.

14.4 Priorities

VyOS CLI is all about priorities. Every CLI node has a corresponding `node.def` file and possibly an attached script that is executed when the node is present. Nodes can have a priority, and on system bootup - or any other `commit` to the config all scripts are executed from lowest to highest priority. This is good as this gives a deterministic behavior.

To debug issues in priorities or to see what's going on in the background you can use the `/opt/vyatta/sbin/priority.pl` script which lists to you the execution order of the scripts.

CHAPTER 15

Documentation

We encourage every VyOS user to help us improve our documentation as we have a deficit like most software projects. This not only helps you when reading but also everyone else.

If you are willing to contribute to our documentation this is the definite guide how to do so.

Note: In contrast to submitting code patches, there is no requirement that you open up a [Phabricator](#) task prior to submitting a Pull-Request to the documentation.

15.1 Forking Workflow

The Forking Workflow is fundamentally different from other popular Git workflows. Instead of using a single server-side repository to act as the “central” codebase, it gives every developer their own server-side repository. This means that each contributor has not one, but two Git repositories: a private local one and a public server-side one.

The main advantage of the Forking Workflow is that contributions can be integrated without the need for everybody to push to a single central repository. Developers push to their own server-side repositories, and only the project maintainer can push to the official repository. This allows the maintainer to accept commits from any developer without giving them write access to the official codebase.

Note: Updates to our documentation should be delivered by a GitHub pull-request. This requires you already have a GitHub account.

- Fork this project on GitHub <https://github.com/vyos/vyos-documentation/fork>
- Clone fork to local machine, then change to that directory `$ cd vyos-documentation`
- Install the requirements `$ pip install -r requirements.txt` (or something similar)
- Create a new branch for your work, use a descriptive name of your work: `$ git checkout -b <branch-name>`

- Make all your changes - please keep our commit rules in mind (*Prepare patch/commit*). This mainly applies to proper commit messages describing your change (how and why). Please check out the documentation of [Sphinx-doc](#) or [reStructuredText](#) if you are not familiar with it. This is used for writing our docs. Additional directives how to write in RST can be obtained from [reStructuredTextDirectives](#).
- Check your changes by locally building the documentation `$ make html`. Sphinx will build the html files in the `docs/_build` folder. We provide you with a Docker container for an easy-to-use user experience. Check the [README.md](#) file of this repository.
- View modified files by calling `$ git status`. You will get an overview of all files modified by you. You can add individual files to the Git Index in the next step.
- Add modified files to Git index `$ git add path/to/filename` or add all unstaged files `$ git add ..`. All files added to the Git index will be part of you following Git commit.
- Commit your changes with the message, `$ git commit -m "<commit message>"` or use `$ git commit -v` to have your configured editor launched. You can type in a commit message. Again please make yourself comfortable without rules (*Prepare patch/commit*).
- Push commits to your GitHub project: `$ git push -u origin <branch-name>`
- Submit pull-request. In GitHub visit the main repository and you should see a banner suggesting to make a pull request. Fill out the form and describe what you do.
- Once pull requests have been approved, you may want to locally update your forked repository too. First you'll have to add a second remote called *upstream* which points to our main repository. `$ git remote add upstream https://github.com/vyos/vyos-documentation.git`

Check your configured remote repositories:

```
$ git remote -v
origin    https://github.com/<username>/vyos-documentation.git (fetch)
origin    https://github.com/<username>/vyos-documentation.git (push)
upstream  https://github.com/vyos/vyos-documentation.git (fetch)
upstream  https://github.com/vyos/vyos-documentation.git (push)
```

Your remote repo on Github is called *origin*, while the original repo you have forked is called *upstream*. Now you can locally update your forked repo.

```
$ git fetch upstream
$ git checkout master
$ git merge upstream/master
```

- If you also want to update your fork on GitHub, use the following: `$ git push origin master`

15.2 Style Guide

15.2.1 Formating and Sphinxmarkup

TOC Level

We use the following syntax for Headlines.

```
#####
Title
#####
```

(continues on next page)

(continued from previous page)

```
*****
Chapters
*****

Sections
=====

Subsections
-----

Subsubsections
^^^^^^^^^^^^^^^^

Paragraphs
" " " " " " " " " "
```

Cross-References

A plugin will be used to generate a reference label for each headline. To reference a page or a section in the documentation use the `:ref:` command.

For example, you want to reference the headline **VLAN** in the **ethernet.rst** page. The plugin generates the label based on the headline and the file path.

```
:ref:`configuration/interfaces/ethernet:vlan
```

to use an alternative hyperlink use it this way:

```
:ref:`Check out VLAN<configuration/interfaces/ethernet:vlan>
```

handle build errors

The plugin will warn on build if a headline has a duplicate name in the same document. To prevent this warning, you have to put a custom link on top of the headline.

```
Section A
=====

Lorem ipsum dolor sit amet, consetetur sadipscing elitr

Example
-----

Lorem ipsum dolor sit amet, consetetur sadipscing elitr

Section B
=====

Lorem ipsum dolor sit amet, consetetur sadipscing elitr

.. _section B example:

Example
-----
```

(continues on next page)

(continued from previous page)

Lorem ipsum dolor sit amet, consetetur sadipscing elitr

Address space

Note the following RFCs ([RFC 5737](#), [RFC 3849](#), [RFC 5389](#) and [RFC 7042](#)), which describe the reserved public IP addresses and autonomous system numbers for the documentation:

- 192.0.2.0/24
- 198.51.100.0/24
- 203.0.113.0/24
- 2001:db8::/32
- 16bit ASN: 64496 – 64511
- 32bit ASN: 65536 – 65551
- Unicast MAC Addresses: 00-53-00 to 00-53-FF
- Multicast MAC-Addresses: 90-10-00 to 90-10-FF

Please do not use other public address space.

Line length

Limit all lines to a maximum of 80 characters.

Except in `.. code-block::` because it uses the html tag `<pre>` and renders the same line format from the source rst file.

Autolinter

Each GitHub pull request is automatically linted to check the address space and line length.

Sometimes it is necessary to provide real IP addresses like in the *Configuration Blueprints*. For this, please use the sphinx comment syntax `.. stop_vyoslint` to stop the linter and `.. start_vyoslint` to start.

Custom Sphinx-doc Markup

Custom commands have been developed for writing the documentation. Please make yourself comfortable with those commands as this eases the way we render the documentation.

cfgcmd

When documenting CLI commands, use the `.. cfgcmd::` directive for all configuration mode commands. An explanation of the described command should be added below this statement. Replace all variable contents with `<value>` or something similar.

With those custom commands, it will be possible to render them in a more descriptive way in the resulting HTML/PDF manual.

```
.. cfgcmd:: protocols static arp <ipaddress> hwaddr <macaddress>
```

This will configure a static ARP entry, always resolving `192.0.2.100` to `00:53:27:de:23:aa`.

For an inline configuration level command, use `:cfgcmd:`

```
:cfgcmd:`set interface ethernet eth0`
```

opcmd

When documenting operational level commands, use the `.. opcmd::` directive. An explanation of the described command should be added below this statement.

With those custom commands, it is possible to render them in a more descriptive way in the resulting HTML/PDF manual.

```
.. opcmd:: show protocols static arp
```

Display all known ARP table entries spanning across all interfaces

For an inline operational level command, use `:opcmd:`

```
:opcmd:`add system image`
```

cmdinclude

To minimize redundancy, there is a special include directive. It includes a txt file and replace the `{{ var0 }}` - `{{ var9 }}` with the correct value.

```
.. cmdinclude:: /_include/interface-address.txt
:var0: ethernet
:var1: eth1
```

the content of interface-address.txt looks like this

```
.. cfgcmd:: set interfaces {{ var0 }} <interface> address <address | dhcp |
dhcpv6>
```

Configure interface ``<interface>`` with one or more interface addresses.

* ****address**** can be specified multiple times as IPv4 and/or IPv6 address, e.g. 192.0.2.1/24 and/or 2001:db8::1/64
 * ****dhcp**** interface address is received by DHCP from a DHCP server on this segment.
 * ****dhcpv6**** interface address is received by DHCPv6 from a DHCPv6 server on this segment.

Example:

```
.. code-block:: none
```

```
set interfaces {{ var0 }} {{ var1 }} address 192.0.2.1/24
```

(continues on next page)

(continued from previous page)

```
set interfaces {{ var0 }} {{ var1 }} address 192.0.2.2/24
set interfaces {{ var0 }} {{ var1 }} address 2001:db8::ffff/64
set interfaces {{ var0 }} {{ var1 }} address 2001:db8:100::ffff/64
```

vytask

When referencing to VyOS Phabricator Tasks, there is a custom Sphinx Markup command called `vytask` that automatically renders to a proper Phabricator URL. This is heavily used in the [Changelog](#) section.

```
* :vytask:`T1605` Fixed regression in L2TP/IPsec server
* :vytask:`T1613` Netflow/sFlow captures IPv6 traffic correctly
```

15.2.2 Page content

The documentation has 3 different types of pages. The same kind of pages must have the same structure to achieve a recognition factor.

All RST files must follow the same TOC Level syntax and have to start with

Configuration mode pages

The configuration mode folder and the articles cover the specific level of the commands. The exact level depends on the command. This should provide stability for URLs used in the forum or blogpost.

For example:

- `set zone-policy` is written in `zone-policy/index.rst`
- `set interfaces ethernet` is written in `interfaces/ethernet.rst`

The article starts with a short introduction about the command or the technology. Please include some helpful links or background information.

An optional section follows. Some commands have requirements like compatible hardware (e.g. Wifi) or some commands you have to set before. For example, it is recommended to set a route-map before configuring BGP.

In the configuration part of the page, all possible configuration options should be documented. Use `.. cfgcmd::` described above.

Related operation command must be documented in the next part of the article. Use `: :opcmd..` for these commands.

If there some troubleshooting guides related to the commands. Explain it in the next optional part.

Operation mode pages

Operation mode commands that do not fit in a related configuration mode command must be documented in this part of the documentation.

General concepts for troubleshooting and detailed process descriptions belong here.

Anything else

Anything else that is not a configuration or an operation command has no predefined structure.

CHAPTER 16

Coverage

Overview over all commands, which are documented in the `.. cfgcmd::` or `.. opcmd::` Directives.

The build process take all xml definition files from `vyos-lx` and extract each leaf command or executable command. After this the commands are compare and shown in the following two tables. The script compare only the fixed part of a command. All variables or values will be erase and then compare:

for example there are these two commands:

- documentation: `interfaces ethernet <interface> address <address | dhcp | dhcpv6>`
- xml: `interface ethernet <ethernet> address <address>`

Now the script erase all in between `<` and `>` and simply compare the strings.

There are 2 kind of problems:

Not documented yet

- A XML command are not found in `.. cfgcmd::` or `.. opcmd::` Commands
- The command should be documented

Nothing found in XML Definitions

- `.. cfgcmd::` or `.. opcmd::` Command are not found in a XML command
- Maybe the command where changed in the XML Definition, or the feature is not anymore in VyOS
- Some commands are not yet translated to XML
