Technical Reference

Technical Reference

Revised Edition (April 1984)

The following paragraph does not apply to the United Kingdom or any country where such provisions are inconsistent with local law: International Business Machines Corporation provides this manual "as is," without warranty of any kind, either expressed or implied, including, but not limited to the particular purpose. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this manual at any time.

This product could include technical inaccuracies or typographical errors. Changes are made periodically to the information herein; these changes will be incorporated in new editions of the publication.

It is possible that this material may contain reference to, or information about, IBM products (machines or programs), programming, or services that are not announced in your country. Such references or information must not be construed to mean that IBM intends to announce such IBM products, programming, or services in your country.

Products are not stocked at the address below. Requests for copies of this product and for technical information about the system should be made to your authorized IBM Personal Computer dealer.

The following paragraph applies only to the United States and Puerto Rico: A Reader's Comment Form is provided at the back of this publication. If the form has been removed, address comments to: IBM Corp., Personal Computer, P.O. Box 1328-C, Boca Raton, Florida 33432. IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligations whatever.

Federal Communications Commission Radio Frequency Interference Statement

Warning: The equipment described herein has been certified to comply with the limits for a Class B computing device, pursuant to Subpart J of Part 15 of the FCC rules. Only peripherals (computer input/output devices, terminals printers, etc.) certified to comply with the Class B limits may be attached to the computer. Operation with non-certified peripherals is likely to result in interference to radio and TV reception. If peripherals not offered by IBM are used with the equipment, it is suggested to use shielded grounded cables with in-line filters if necessary.

CAUTION

The product described herein is equipped with a grounded plug for the user's safety. It is to be used in conjunction with a properly grounded receptacle to avoid electrical shock.

Preface

This publication describes the various units of the IBM Personal Computer; and the interaction of each.

The information in this publication is for reference, and is intended for hardware and program designers, programmers, engineers, and anyone else with a knowledge of electronics and/or programming who needs to understand the design and operation of the IBM Personal Computer.

This publication consists of two parts: a system manual and an options and adapters manual.

The system manual is divided into the following sections:

Section 1, "System Board," discusses the component layout, circuitry, and function of the system board.

Section 2, "Coprocessor," describes the Intel 8087 coprocessor and provides programming and hardware interface information.

Section 3, "Power Supply," provides electrical input/output specifications as well as theory of operation for the IBM Personal Computer power supply.

Section 4, "Keyboard," discusses the hardware make up, function, and layout of the IBM Personal Computer keyboard.

Section 5, "System BIOS," describes the basic input/output system and its use. This section also contains the software interrupt listing, a BIOS memory map, descriptions of vectors with special meanings, and a set of low memory maps. In addition, keyboard encoding and usage is discussed.

Section 6, "Instruction Set," provides a quick reference for the 8088 assembly instruction set.

Section 7, "Characters, Keystrokes, and Colors," supplies the decimal and hexadecimal values for characters and text attributes.

Section 8, "Communications," describes communications hardware and discusses communications interface standards and the sequence of events to establish communications.

A glossary, bibliography, and index are also provided.

The options and adapters manual provides information, logic diagrams, and specifications pertaining to the options and adapters available for the IBM Personal Computer family of products. The manual is modular in format, with each module providing information about a specific option or adapter. Modules having a large amount of text contain individual indexes. The modules are grouped by type of device into the following categories:

- Expansion Unit
- Displays
- Printers
- Storage Devices
- · Memory Expansion
- Adapters
- Miscellaneous
- Cables and Connectors

Full page length hard tabs with the above category descriptions, separate the groups of modules.

The term "Technical Reference manual" in the option and adapter manual, refers to the IBM Personal Computer Technical Reference system manual.

The term "Guide to Operations manual" in the option and adapter manual, refers to the IBM Personal Computer Guide to Operations manual.

Description

The system board fits horizontally in the base of the system unit and is approximately 215.5 mm (8-1/2 in.) x 304.8 mm (12 in.). It is a multilayer, single-land-per-channel design with ground and internal planes provided. Dc power and a signal from the power supply enter the board through two six-pin connectors. Other connectors on the board are for attaching the keyboard, audio cassette and speaker. Five 62-pin card edge-sockets are also mounted on the board. The I/O channel is bussed across these five I/O slots.

Two dual-in-line package (DIP) switches (two eight-switch packs) are mounted on the board and can be read under program control. The DIP switches provide the system software with information about the installed options, how much storage the system board has, what type of display adapter is installed, what operation modes are desired when power is switched on (color or black-and-white, 80 or 40-character lines), and the number of diskette drives attached.

The system board consists of five functional areas: the microprocessor subsystem and its support elements, the read-only memory (ROM) subsystem, the read/write (R/W) memory subsystem, integrated I/O adapters, and the I/O channel. The read/write memory is also referred to as random access memory (RAM). All are described in this section.

Microprocessor

The heart of the system board is the Intel 8088 Microprocessor. This is an 8-bit external-bus version of Intel's 16-bit 8086 Microprocessor, and is software-compatible with the 8086. Thus, the 8088 supports 16-bit operations, including multiply and divide, and supports 20 bits of addressing (1 megabyte of storage). It also operates in maximum mode, so a comicroprocessor can be added as a feature. The microprocessor operates at 4.77-MHz. This frequency, which is derived from a

14.31818-MHz crystal, is divided by 3 for the microprocessor clock, and by 4 to obtain the 3.58-MHz color burst signal required for color televisions.

At the 4.77-MHz clock rate, the 8088 bus cycles are four clocks of 210-ns, or 840-ns. I/O cycles take five 210-ns clocks or $1.05-\mu s$.

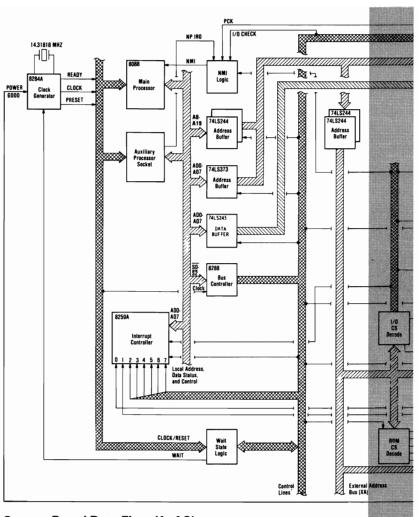

The system board contains circuits for attaching an audio cassette, the keyboard, and the speaker. The cassette adapter allows the attachment of any good quality audio cassette through the earphone output and either the microphone or auxiliary inputs. The system board has a jumper for either input. This interface also provides a cassette motor control for transport starting and stopping under program control. This interface reads and writes the audio cassette at a data rate of between 1,000 and 2,000 baud. The baud rate is variable and depend on data content, because a different bit-cell time is used for 0's and 1's. For diagnostic purposes, the tape interface can loop read to write for testing the system board's circuits. The ROM cassette software blocks cassette data and generates a cyclic redundancy check (CRC) to check this data.

The system board contains the adapter circuits for attaching the serial interface from the keyboard. These circuits generate an interrupt to the microprocessor when a complete scan code is received. The interface can request execution of a diagnostic test in the keyboard.

Both the keyboard and cassette interfaces on the system board are 5-pin DIN connectors that extends through the rear panel of the system unit.

System Memory Map for 64/256K System Board (Part 2 of 2)

System Timers

Three programmable timer/counters are used by the system as follows: Channel 0 is a general-purpose timer providing a constant time base for implementing a time-of-day clock, Channel 1 times and requests refresh cycles from the Direct Memory Access (DMA) channel, and Channel 2 supports the tone generation for the speaker. Each channel has a minimum timing resolution of $1.05-\mu s$.

System Interrupts

Of the eight prioritized levels of interrupt, six are bussed to the system expansion slots for use by feature cards. Two levels are used on the system board.

Level 0, the highest priority, is attached to Channel 0 of the timer/counter and provides a periodic interrupt for the time-of-day clock.

Level 1 is attached to the keyboard adapter circuits and receives an interrupt for each scan code sent by the keyboard. The non-maskable interrupt (NMI) of the 8088 is used to report memory parity errors.

8088 Hardware Interrupt Listing

ROM

The system board supports both Read Only Memory (ROM) and Random Access Memory (RAM). It has space for up to 512K of ROM or Eraseable Programmable ROM (EPROM). Six module sockets are provided, each of which can accept an 8K or 8 byte device. Five sockets are populated with 40K of ROM. This ROM contains the cassette BASIC interpreter, cassette operating system, power-on selftest, Input/Output (I/O) drivers, dot patterns for 128 characters in graphics mode, and a diskette bootstrap loader. The ROM is packaged in 28-pin modules and has an access time of 250-ns and a cycle time of 375-ns.

RAM

The RAM on the system board is as shown in the following chart.

System Board	Minimum	Maximum	Memory	Soldered	Pluggable
	Storage	Storage	Modules	(Bank 0)	(Bank 1-3)
64/256K	64K	256K	64K by 1 Bit	1 Bank of 9	3 Banks of 9

Memory greater than the system board's maximum is obtained by adding memory cards in the expansion slots. All memory is parity-checked and consists of dynamic 64K by 1 bit chips with an access time of 250-ns and a cycle time of 410-ns.

DMA

The microprocessor is supported by a set of high-function support devices providing four channels of 20-bit direct-memory access (DMA), three 16-bit timer/counter channels, and eight prioritized interrupt levels.

Three of the four DMA channels are available on the I/O bus and support high-speed data transfers between I/O devices and memory without microprocessor intervention. The fourth DMA channel is programmed to refresh the system dynamic memory. This is done by programming a channel of the timer/counter device to periodically request a dummy DMA transfer. This action creates a memory-read cycle, which is available to refresh dynamic storage both on the system board and in the system expansion slots. All DMA data transfers, except the refresh channel, take five microprocessor clocks of 210-ns, or $1.05-\mu s$ if the microprocessor ready line is not deactivated. Refresh DMA cycles take four clocks or 840-ns.

The three programmable timer/counter devices are used by the system as follows: Channel 0 is used as a general-purpose timer providing a constant time base for implementing a time-of-day clock; Channel 1 is used to time and request refresh cycles from the DMA channel; and Channel 2 is used to support the tone generation for the speaker. Each channel has a minimum timing resolution of 1.05-us.

Of the eight prioritized levels of interrupt, six are bussed to the system expansion slots for use by feature cards. Two levels are used on the system board. Level 0, the highest priority, is attached to Channel 0 of the timer/counter device and provides a periodic interrupt for the time-of-day clock. Level 1 is attached to the keyboard adapter circuits and receives an interrupt for each scan code sent by the keyboard. The non-maskable interrupt (NMI) of the 8088 is used to report memory parity errors.

I/O Channel

The I/O channel is an extension of the 8088 microprocessor bus. It is, however, demultiplexed, repowered, and enhanced by the addition of interrupts and direct memory access (DMA) functions.

The I/O channel contains an 8-bit bidirectional data bus, 20 address lines, 6 levels of interrupt, control lines for memory and I/O read or write, clock and timing lines, 3 channels of DMA

control lines, memory refresh timing control lines, a channel-check line, and power and ground for the adapters. Four voltage levels are provided for I/O cards: +5 Vdc, -5 Vdc, +12 Vdc, and -12 Vdc. These functions are provided in a 62-pin connector with 100-mil card tab spacing.

A 'ready' line is available on the I/O channel to allow operation with slow I/O or memory devices. If the channel's ready line is not activated by an addressed device, all microprocessor-generated memory read and write cycles take four 210-ns clocks or 840-ns/byte. All microprocessor-generated I/O read and write cycles require five clocks for a cycle time of 1.05- μ s/byte. All DMA transfers require five clocks for a cycle time of 1.05- μ s/byte. Refresh cycles occur once every 72 clocks (approximately 15- μ s) and require four clocks or approximately 1% of the bus bandwidth.

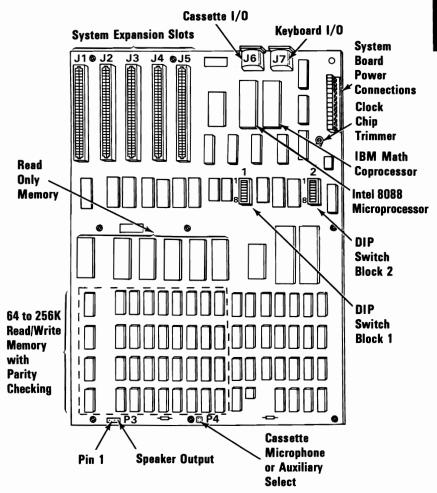

I/O devices are addressed using I/O mapped address space. The channel is designed so that 512 I/O device addresses are available to the I/O channel cards.

A 'channel check' line exists for reporting error conditions to the microprocessor. Activating this line results in a non-maskable interrupt (NMI) to the 8088 microprocessor. Memory expansion options use this line to report parity errors.

The I/O channel is repowered to provide sufficient drive to power all five system unit expansion slots, assuming two low-power Schottky loads per slot. The IBM I/O adapters typically use only one load.

System Board Diagram

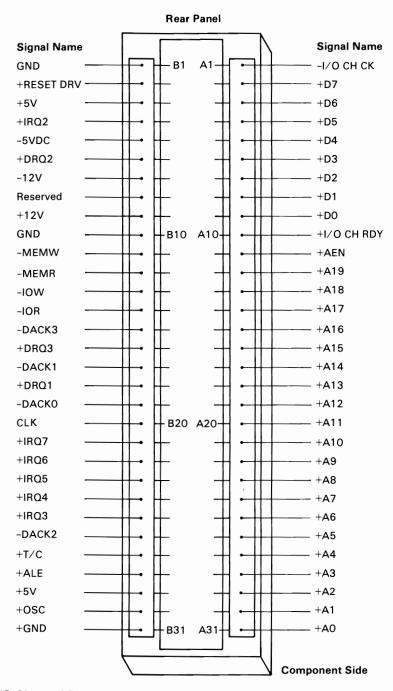

The following shows the system board's component layout.

System Board Component Diagram

I/O Channel Diagram

The following page contains the I/O Channel Diagram. All lines are TTL-compatible.

I/O Channel Diagram

I/O Channel Description

The following is a description of the IBM Personal Computer I/O Channel. All lines are TTL-compatible.

Signal	I/O	Description
A0-A19	Ο	Address bits 0 to 19: These lines are used to address memory and I/O devices within the system. The 20 address lines allow access of up to 1M-byte of memory. A0 is the least significant bit (LSB) and A19 is the most significant bit (MSB). These lines are generated by either the microprocessor or DMA controller. They are active high.
AEN	Ο	Address Enable: This line is used to de-gate the microprocessor and other devices from the I/O channel to allow DMA transfers to take place. When this line is active (high), the DMA controller has control of the address bus, data bus, Read command lines (memory and I/O), and the Write command lines (memory and I/O).
ALE	O	Address Latch Enable: This line is provided by the 8288 Bus Controller and is used on the system board to latch valid addresses from the microprocessor. It is available to the I/O channel as an indicator of a valid microprocessor address (when used with AEN). Microprocessor addresses are latched with the falling edge of ALE.
CLK	O	System clock: It is a divide-by-three of the oscillator and has a period of 210-ns (4.77-MHz) The clock has a 33% duty cycle.

D0-D7

I/O Data Bits 0 to 7: These lines provide data bus bits 0 to 7 for the microprocessor, memory, and I/O devices. D0 is the least significant bit (LSB) and D7 is the most significant bit (MSB). These lines are active high.

-DACK0 to -DACK3 -DMA Acknowledge 0 to 3: These lines are used to acknowledge DMA requests (DRQ1-DRQ3) and refresh system dynamic memory (-DACK0). They are active low.

DRQ1-DRQ3 I DMA Request 1 to 3: These lines are asynchronous channel requests used by peripheral devices to gain DMA service. They are prioritized with DRQ3 being the lowest and DRQ1 being the highest. A request is generated by bringing a DRQ line to an active level (high). A DRQ line must be held high until the corresponding DACK line goes active.

-I/O CH CK I -I/O Channel Check: This line provides the microprocessor with parity (error) information on memory or devices in the I/O channel. When this signal is active low, a parity error is indicated.

I/O CH RDY I J/O Channel Ready: This line, normally high (ready), is pulled low (not ready) by a memory or I/O device to lengthen I/O or memory cycles. It allows slower devices to attach to the I/O channel with a minimum of difficulty. Any slow device using this line should drive it low immediately upon detecting a valid address and a Read or Write command. This line should never be held low longer than 10

clock cycles. Machine cycles (I/O or memory) are extended by an integral number of clock cycles (210-ns).

-IOR

-I/O Read Command: This command line instructs an I/O device to drive its data onto the data bus. It may be driven by the microprocessor or the DMA controller. This signal is active low.

-IOW

O -I/O Write Command: This command line instructs an I/O device to read the data on the data bus. It may be driven by the microprocessor or the DMA controller. This signal is active low.

IRQ2-IRQ7 I

O

Interrupt Request 2 to 7: These lines are used to signal the microprocessor that an I/O device requires attention. They are prioritized with IRQ2 as the highest priority and IRQ7 as the lowest. An Interrupt Request is generated by raising an IRQ line (low to high) and holding it high until it is acknowledged by the microprocessor (interrupt service routine).

-MEMR

O -Memory Read Command: This command line instructs the memory to drive its data onto the data bus. It may be driven by the microprocessor or the DMA controller. This signal is active low.

-MEMW

O

-Memory Write Command: This command line instructs the memory to store the data present on the data bus. It may be driven by the microprocessor or the DMA controller. This signal is active low.

OSC
Oscillator: High-speed clock with a 70-ns period (14.31818-MHz). It has a 50% duty cycle.

RESET DRV
ORESET Drive: This line is used to reset or initialize system logic upon power-up or during a low line-voltage outage. This signal is synchronized to the falling edge of CLK and is active high.

T/C

O Terminal Count: This line provides a pulse when the terminal count for any DMA channel is reached. This signal is active high.

^{*} These are the addresses decoded by the current set of adapter cards. IBM may use any of the unlisted addresses for future use.

Set mask: Write hex 80 to I/O Address hex A0 (enable NMI)

Clear mask: Write hex 00 to I/O Address hex A0 (disable NMI)

I/O Address Map

^{**} At power-on time, the Non Mask Interrupt into the 8088 is masked off. This mask bit can be set and reset through system software as follows:

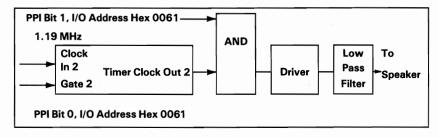

^{***} SDLC Communications and Secondary Binary Synchronous Communications cannot be used together because their hex addresses overlap.

Other Circuits

Speaker Circuit

The sound system has a small, permanent magnet, 57.15 mm (2-1/4 in.) speaker. The speaker can be driven from one or both of two sources:

- An 8255A-5 programmable peripheral interface (PPI) output bit. The address and bit are defined in the "I/O Address Map".
- A timer clock channel, the output of which is programmable within the functions of the 8253-5 timer when using a 1.19-MHz clock input. The timer gate also is controlled by an 8255A-5 PPI output-port bit. Address and bit assignment are in the "I/O Address Map".

Speaker Drive System Block Diagram

```
Channel 2 (Tone generation for speaker)
Gate 2 — Controller by 8255A-5 PPI Bit
(See I/O Map)
Clock In 2 — 1.19318 - MHz OSC
Clock Out 2 — Used to drive speaker
```

Speaker Tone Generation

The speaker connection is a 4-pin Berg connector. See "System Board Component Diagram," earlier in this section, for speaker connection or placement.

Pin	Function
1	Data
2	Key
3	Ground
4	+ 5 Volts

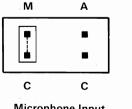

Speaker Connector

The speaker drive circuit is capable of about 1/2 watt of power. The control circuits allow the speaker to be driven three ways: (1) a direct program control register bit may be toggled to generate a pulse train; (2) the output from Channel 2 of the timer/counter device may be programmed to generate a waveform to the speaker; (3) the clock input to the timer/counter device can be modulated with a program-controlled I/O register bit. All three methods may be performed simultaneously.

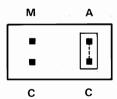

Cassette Interface

The cassette interface is controlled through software. An output from the 8253 timer controls the data to the cassette recorder through pin 5 of the cassette DIN connector at the rear of the system board. The cassette input data is read by an input port bit of the 8255A-5 PPI. This data is received through pin 4 of the cassette connector. Software algorithms are used to generate and read cassette data. The cassette drive motor is controlled through pins 1 and 3 of the cassette connector. The drive motor on/off switching is controlled by an 8255A-5 PPI output-port bit (hex 61, bit 3). The 8255A-5 address and bit assignments are defined in "I/O Address Map" earlier in this section.

A 2 by 2 Berg pin and a jumper are used on the cassette 'data out' line. The jumper allows use of the 'data out' line as a 0.075-Vdc microphone input when placed across the M and C of the Berg Pins. A 0.68-Vdc auxiliary input to the cassette recorder is available when the jumper is placed across the A and C of the Berg Pins. The "System Board Component Diagram" shows the location of the cassette Berg pins.

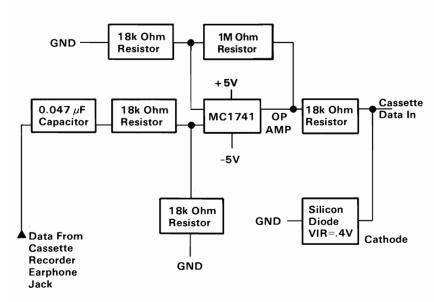

Microphone Input (0.075 Vdc)

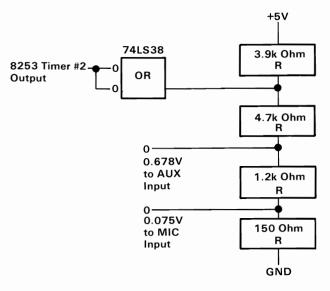

Auxiliary Input (0.68 Vdc)

Cassette Circuit Block Diagrams

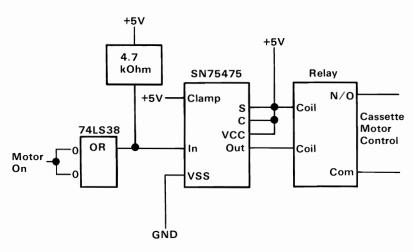

Circuit block diagrams for the cassette-interface read hardware, write hardware, and motor control are illustrated below.

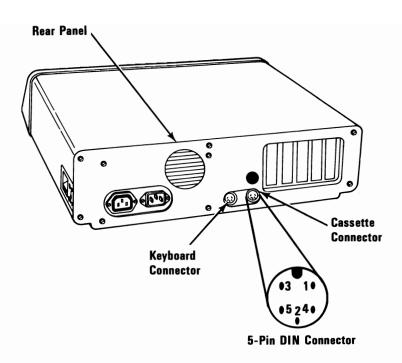

Cassette-Interface Read Hardware Block Diagram

Cassette Interface Write Hardware Block Diagram

Cassette Motor Control Block Diagram

Pin	Signal	Electrical Characteristics		
1	Motor Control	Common from Relay		
2	Ground			
3	Motor Control	Relay N.O. (6 Vdc at 1A)		
4	Data In	500nA at ± 13V - at 1,000 - 2,000 Baud		
5	Data Out (Microphone or Auxiliary)	250 μA at 0.68 Vdc or ** 0.075 Vdc		

^{*}All voltages and currents are maximum ratings and should not be exceeded.

Interchange of these voltages on the cassette recorder could lead to damage of recorder inputs.

Cassette Interface Connector Specifications

^{**}Data out can be chosen using a jumper located on the system board. (Auxiliary →0.68 Vdc or Microphone →0.075 Vdc).

8255A I/O Bit Map

The 8255A I/O Bit Map shows the inputs and outputs for the Command/Mode register on the system board. Also shown are the switch settings for the memory, display, and number of diskette drives. The following page contains the I/O bit map.

8255A I/O Bit Map

1-32 System Board

System-Board Switch Settings

All system board switch settings for total system memory, number of diskette drives, and type of display adapter are described under "Switch Settings" in the IBM Personal Computer *Guide to Operations*. The diagram showing the system board switch locations follows.

Specifications

The following voltages are available on the system-board I/O channel:

```
+ 5 Vdc ± 5% on 2 connector pins

- 5 Vdc ±10% on 1 connector pin

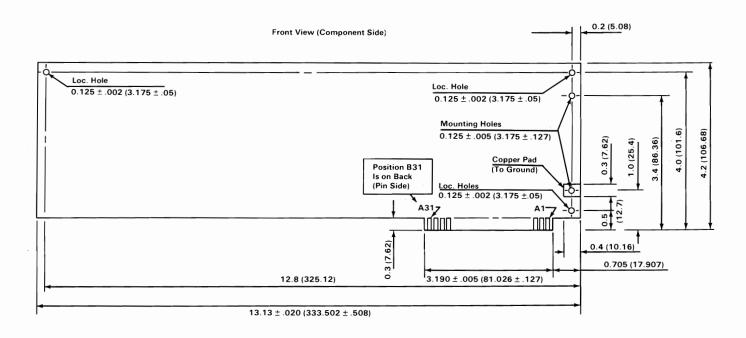

+12 Vdc ± 5% on 1 connector pin

-12 Vdc ±10% on 1 connector pin

GND (Ground) on 3 connector pins
```

Card Specifications

The specifications for option cards follow.

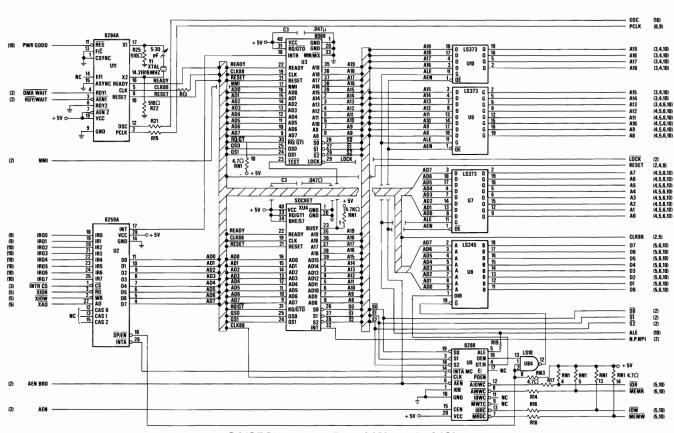

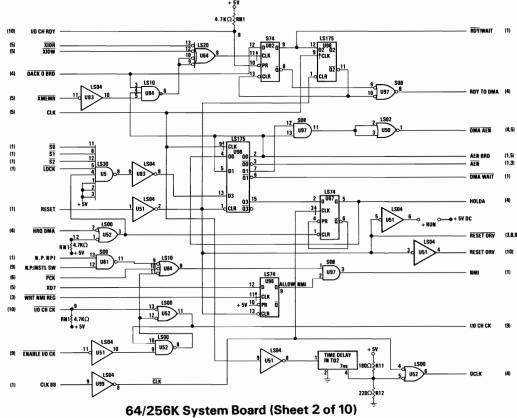

Notes:

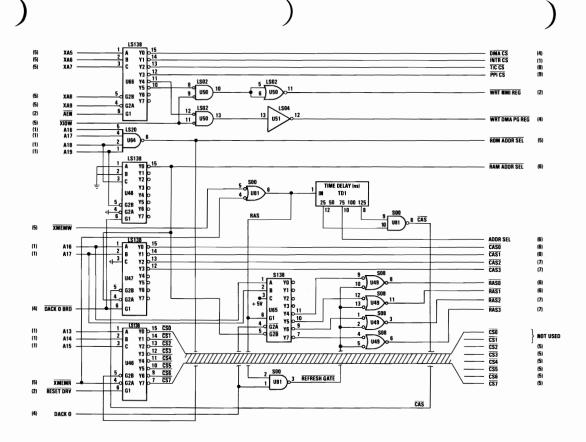

- All Card Dimensions
 are ± .010 (.254) Tolerance
 (With Exceptions Indicated
 on Drawing or in Notes).
- 2. Max. Card Length is 13.15 (334.01) Smaller Length is Permissible.
- 3. Loc. and Mounting Holes are Non-Plated Thru. (Loc. 3X, Mtg. 2X).
- 31 Gold Tabs Each Side, 0.100 ± .0005 (2.54 ± .0127) Center to Center, 0.06 ± .0005 (1.524 ± .0127) Width.
- 5. Numbers in Parentheses are in Millimeters. All Others are in Inches.

Logic Diagrams

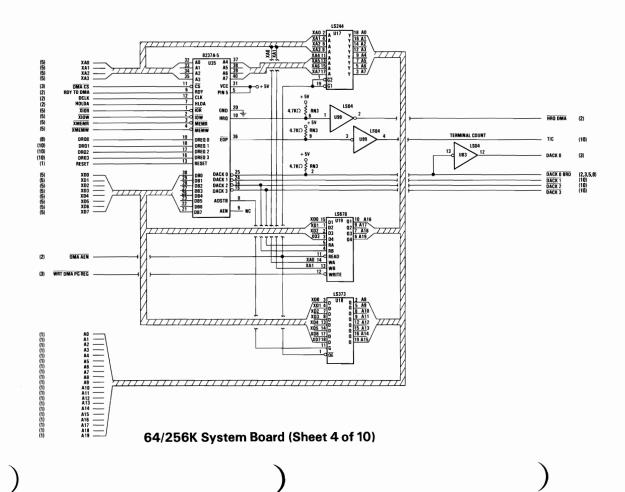

The following pages contain the logic diagrams for the system board.

SECTION 2. COPROCESSOR

Contents

Description	• • • • • • • •	• • • • •	 	2-3
Programming	g Interface		 	2-3

Hardware Interface 2--

Description

The Math Coprocessor (8087) enables the IBM Personal Computer to perform high-speed arithmetic, logarithmic functions, and trigonometric operations with extreme accuracy.

The 8087 coprocessor works in parallel with the microprocessor. The parallel operation decreases operating time by allowing the coprocessor to do mathematical calculations while the microprocessor continues to do other functions.

The first five bits of every instruction's operation code for the coprocessor are identical (binary 11011). When the microprocessor and the coprocessor see this operation code, the microprocessor calculates the address of any variables in memory, while the coprocessor checks the instruction. The coprocessor takes the memory address from the microprocessor if necessary. To gain access to locations in memory, the coprocessor takes the local bus from the microprocessor when the microprocessor finishes its current instruction. When the coprocessor is finished with the memory transfer, it returns the local bus to the microprocessor.

The IBM Math Coprocessor works with seven numeric data types divided into the three classes listed below.

- Binary integers (3 types)
- Decimal integers (1 type)
- Real numbers (3 types)

Programming Interface

The coprocessor extends the data types, registers, and instructions to the microprocessor.

The coprocessor has eight 80-bit registers, which provide the equivalent capacity of the 40 16-bit registers found in the microprocessor. This register space allows constants and temporary results to be held in registers during calculations, thus reducing memory access and improving speed as well as bus availability. The register space can be used as a stack or as a fixed register set. When used as a stack, only the top two stack elements are operated on. The figure below shows representations of large and small numbers in each data type.

Data Type	Bits	Significant Digits (Decimal)	Approximate Range (decimal)
Word Integer	16	4	-32,768≤X≤+32,767
Short Integer	32	9	$-2x10^9 \le X \le +2x10^9$
Long Integer	64	18	$-9x10^{18} \le X \le +9x10^{18}$
Packed Decimal	80	18	$-9999 \le X \le +9999$ (18 digits)
Short Real*	32	6-7	$8.43 \times 10^{-37} \le X \le 3.37 \times 10^{38}$
Long Real*	64	15-16	$4.19 \times 10^{-307} \le X \le 1.67 \times 10^{308}$
Temporary Real	80	19	$3.4 \times 10^{-4932} \le X \le 1.2 \times 10^{4932}$

^{*}The short and long real data types correspond to the single and double precision data types.

Data Types

Hardware Interface

The coprocessor uses the same clock generator and system bus interface components as the microprocessor. The coprocessor is wired directly into the microprocessor. The microprocessor's queue status lines (QS0 and QS1) enable the coprocessor to obtain and decode instructions simultaneously with the microprocessor. The coprocessor's 'busy' signal informs the microprocessor that it is executing; the microprocessor's WAIT instruction forces the microprocessor to wait until the coprocessor is finished executing (WAIT FOR NOT BUSY).

When an incorrect instruction is sent to the coprocessor (for example, divide by 0 or load a full register), the coprocessor can

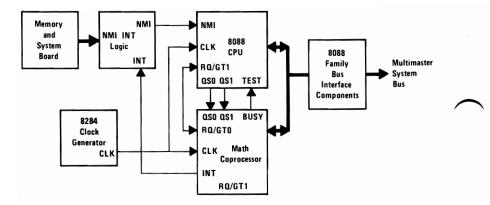

signal the microprocessor with an interrupt. There are three conditions that will disable the coprocessor interrupt to the microprocessor:

- 1. Exception and interrupt-enable bits of the control word are set to 1's.
- 2. System-board switch-block 1, switch 2, set in the On position.
- 3. Non-maskable interrupt (NMI) register (REG) is set to zero.

At power-on time, the NMI REG is cleared to disable the NMI. Any program using the coprocessor's interrupt capability must ensure that conditions 2 and 3 are never met during the operation of the software or an "Endless WAIT" will occur. An "Endless WAIT" will have the microprocessor waiting for the 'not busy' signal from the coprocessor while the coprocessor is waiting for the microprocessor to interrupt.

Because a memory parity error may also cause an interrupt to the microprocessor NMI line, the program should check the coprocessor status for an exception condition. If a coprocessor exception condition is not found, control should be passed to the normal NMI handler. If an 8087 exception condition is found, the program may clear the exception by executing the FNSAVE or the FNCLEX instruction, and the exception can be identified and acted upon.

The NMI REG and the coprocessor's interrupt are tied to the NMI line through the NMI interrupt logic. Minor modifications to programs designed for use with a coprocessor must be made before the programs will be compatible with the IBM Personal Computer Math Coprocessor.

Coprocessor Interconnection

Detailed information for the internal functions of the Intel 8087 Coprocessor can be found in the books listed in the Bibliography.

SECTION 3. POWER SUPPLY

Description

The system power supply is located at the right rear of the system unit. It is an integral part of the system-unit chassis. Its housing provides support for the rear panel, and its fan furnishes cooling for the whole system.

It supplies the power and reset signal necessary for the operation of the system board, installed options, and the keyboard. It also provides a switched ac socket for the IBM Monochrome Display and two separate connectors for power to the 5-1/4 inch diskette drives.

The two different power supplies available are designed for continuous operation at 63.5 Watts. They have a fused 120 Vac or 220/240 Vac input and provide four regulated dc output voltages: 7 A at +5 Vdc, 2 A at +12 Vdc, 0.3 A at -5 Vdc, and 0.25 A at -12 Vdc. These outputs are overvoltage, overcurrent, open-circuit, and short-circuit protected. If a dc overload or overvoltage condition occurs, all dc outputs are shut down as long as the condition exists.

The +12 Vdc and -12 Vdc power the EIA drivers and receivers on the asynchronous communications adapter. The +12 Vdc also power's the system's dynamic memory and the two internal 5-1/4 inch diskette drive motors. It is assumed that only one drive is active at a time. The +5 Vdc powers the logic on the system board and diskette drives and allows about 4 A of +5 Vdc for the adapters in the system-unit expansion slots. The -5 Vdc is for dynamic memory bias voltage; it tracks the +5 Vdc and +12 Vdc very quickly at power-on and has a longer decay on power-off than the +5 Vdc and +12 Vdc outputs. All four power supply dc voltages are bussed across each of the five system-unit expansion slots.

Input Requirements

The following are the input requirements for the system unit power supply.

	Voltage (Vac)		Frequency (Hz)	Current (Amps)
Nominal	Minimum	Maximum	+/- 3Hz	Maximum
120	104	127	60	2.5 at 104 Vac
220/240	180	259	50	1.0 at 180 Vac

Outputs

Vdc Output

The following are the dc outputs for the system unit power supply.

Voltage (Vdc)	Current (Amps)		Regulation (Tolerance)
Nominal	Minimum	Maximum	+%	- %
+5.0 -5.0 +12.0 -12.0	2.3 0.0 0.4 0.0	7.0 0.3 2.0 0.25	5 10 5 10	4 8 4 9

Vac Output

The power supply provides a filtered, fused, ac output that is switched on and off with the main power switch. The maximum current available at this output is 0.75 A. The receptacle provided at the rear of the power supply for this ac output is a nonstandard connector designed to be used only for the IBM Monochrome Display.

Overvoltage/Overcurrent Protection

The system power supply employs the protection features which are described below.

Primary (Input)

The following table describes the primary (input voltage) protection for the system-unit power supply.

Voltage (Nominal Vac)	Type Protection	Rating (Amps)
120	Fuse	2
220/240	Fuse	1

Secondary (Output)

On overvoltage, the power supply is designed to shut down all outputs when either the +5 Vdc or the +12 Vdc output exceeds 200% of its maximum rated voltage. On overcurrent, the supply will turn off if any output exceeds 130% of its nominal value.

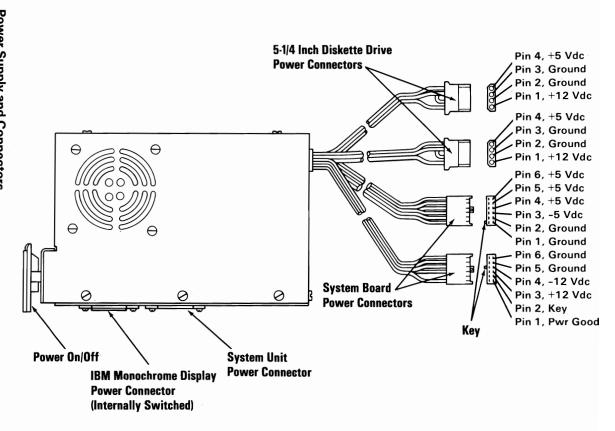

Power Good Signal

When the power supply is turned on after it has been off for a minimum of 5 seconds, it generates a 'power good' signal that indicates there is adequate power for processing. When the four output voltages are above the minimum sense levels, as described below, the signal sequences to a TTL-compatible up level (2.4 Vdc to 5.5 Vdc), is capable of sourcing $60 \mu A$. When any of the four output voltages is below its minimum sense level or above its maximum sense level, the 'power good' signal will be TTL-compatible down level (0.0 Vdc to 0.4 Vdc) capable of supplying $500 \mu A$. The 'power good' signal has a turn-on delay of 100-ms after the output voltages have reached their respective minimum sense levels

Output Voltage	Under-Voltage Nominal Sense Level	Over-Voltage Nominal Sense Level
+ 5 Vdc	+ 4.0 Vdc	+ 5.9 Vdc
– 5 Vdc	- 4.0 Vdc	- 5.9 Vdc
+ 12 Vdc	+ 9.6 Vdc	+ 14.2 Vdc
– 12 Vdc	- 9.6 Vdc	- 14.2 Vdc

Power Supply Connectors and Pin Assignments

The power connector on the system board is a 12-pin male connector that plugs into the power-supply connectors. The pin configuration and locations follow.

SECTION 4. KEYBOARD

Contents

Description 4	- 3
Block Diagram 4	-4
Keyboard Diagrams 4	-5
Connector Specifications 4-	12
Keyboard Logic Diagram 4-	13

Description

The IBM Personal Computer keyboard has a permanently attached cable that connects to a DIN connector at the rear of the system unit. This shielded 5-wire cable has power (+5 Vdc), ground, two bidirectional signal lines, and one wire used as a 'reset' line. The cable is approximately 182.88 cm (6 ft) long and is coiled, like that of a telephone handset.

The keyboard uses a capacitive technology with a microprocessor (Intel 8048) performing the keyboard scan function. The keyboard has two tilt positions for operator comfort (5- or 15-degree tilt orientation).

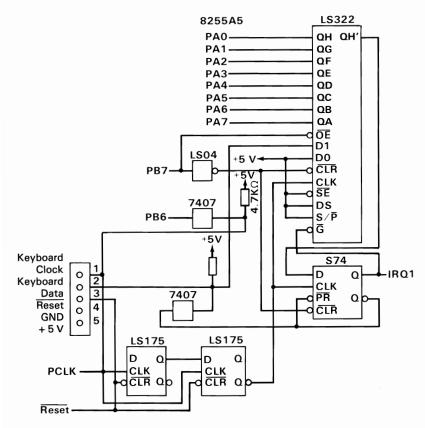

The keyboard has 83 keys arranged in three major groupings. The central portion of the keyboard is a standard typewriter keyboard layout. On the left side are 10 function keys. These keys are defined by the software. On the right is a 15-key keypad. These keys are also defined by the software, but have legends for the functions of numeric entry, cursor control, calculator pad, and screen edit.

The keyboard interface is defined so that system software has maximum flexibility in defining certain keyboard operations. This is accomplished by having the keyboard return scan codes rather than American Standard Code for Information Interchange (ASCII) codes. In addition, all keys are typematic (if held down, they will repeat) and generate both a make and a break scan code. For example, key 1 produces scan code hex 01 on make and code hex 81 on break. Break codes are formed by adding hex 80 to make codes. The keyboard I/O driver can define keyboard keys as shift keys or typematic, as required by the application.

The microprocessor (Intel 8048) in the keyboard performs several functions, including a power-on self test when requested by the system unit. This test checks the microprocessor (Intel 8048) ROM, tests memory, and checks for stuck keys. Additional functions are keyboard scanning, buffering of up to 16 key scan codes, maintaining bidirectional serial communications with the system unit, and executing the handshake protocol required by each scan-code transfer.

Several keyboard arrangements are available. These are illustrated on the following pages. For information about the keyboard routines required to implement non-U.S. keyboards, refer to the *Guide to Operations* and *DOS* manuals.

System BIOS Usage

The basic input/output system (BIOS) resides in ROM on the system board and provides device level control for the major I/O devices in the system. Additional ROM modules may be located on option adapters to provide device level control for that option adapter. BIOS routines enable the assembler language programmer to perform block (disk and diskette) or character-level I/O operations without concern for device address and operating characteristics. System services, such as time-of-day and memory size determination, are provided by the BIOS.

The goal is to provide an operational interface to the system and relieve the programmer of the concern about the characteristics of hardware devices. The BIOS interface insulates the user from the hardware, thus allowing new devices to be added to the system, yet retaining the BIOS level interface to the device. In this manner, user programs become transparent to hardware modifications and enhancements.

The IBM Personal Computer MACRO Assembler manual and the IBM Personal Computer Disk Operating System (DOS) manual provide useful programming information related to this section. A complete listing of the BIOS is given in this section.

Access to the BIOS is through the 8088 software interrupts. Each BIOS entry point is available through its own interrupt.

The software interrupts, hex 10 through hex 1A, each access a different BIOS routine. For example, to determine the amount of memory available in the system,

INT 12H

invokes the BIOS routine for determining memory size and returns the value to the caller.

Parameter Passing

All parameters passed to and from the BIOS routines go through the 8088 registers. The prologue of each BIOS function indicates the registers used on the call and the return. For the memory size example, no parameters are passed. The memory size, in 1K-byte increments, is returned in the AX register.

If a BIOS function has several possible operations, the AH register is used at input to indicate the desired operation. For example, to set the time of day, the following code is required:

MOV AH,1 ;function is to set time of day.

MOV CX,HIGH COUNT ;establish the current time.

MOV DX,LOW_COUNT

INT 1AH ;set the time.

To read the time of day:

MOV AH,0 ; function is to read time of day.

INT 1AH ;read the timer.

Generally, the BIOS routines save all registers except for AX and the flags. Other registers are modified on return only if they are returning a value to the caller. The exact register usage is in the prologue of each BIOS function.

Address (Hex)	Interrupt Number	Name	BIOS Entry

8088 Software Interrupt Listing

Vectors with Special Meanings

Interrupt Hex 1B - Keyboard Break Address

This vector points to the code to be used when the Ctrl and Break keys are pressed on the keyboard. The vector is invoked while responding to the keyboard interrupt, and control should be returned through an IRET instruction. The power-on routines initialize this vector to an IRET instruction, so that nothing will occur when the Ctrl and Break keys are pressed unless the application program sets a different value.

Control may be retained by this routine, with the following problems. The Break may have occurred during interrupt processing, so that one or more End of Interrupt commands must be sent to the 8259 Controller. Also, all I/O devices should be reset in case an operation was underway at that time.

Interrupt Hex 1C - Timer Tick

This vector points to the code to be executed on every system-clock tick. This vector is invoked while responding to the timer interrupt, and control should be returned through an IRET instruction. The power-on routines initialize this vector to point to an IRET instruction, so that nothing will occur unless the application modifies the pointer. It is the responsibility of the application to save and restore all registers that will be modified.

Interrupt Hex 1D - Video Parameters

This vector points to a data region containing the parameters required for the initialization of the 6845 on the video card. Note that there are four separate tables, and all four must be reproduced if all modes of operation are to be supported. The power-on routines initialize this vector to point to the parameters contained in the ROM video routines.

Interrupt Hex 1E - Diskette Parameters

This vector points to a data region containing the parameters required for the diskette drive. The power-on routines initialize the vector to point to the parameters contained in the ROM diskette routine. These default parameters represent the specified values for any IBM drives attached to the system. Changing this parameter block may be necessary to reflect the specifications of the other drives attached.

Interrupt Hex 1F - Graphics Character Extensions

When operating in the graphics modes of the IBM Color/Graphics Monitor Adapter (320 by 200 or 640 by 200), the read/write character interface forms the character from the ASCII code point, using a set of dot patterns. The dot patterns for the first 128 code points are contained in ROM. To access the second 128 code points, this vector must be established to point at a table of up to 1K bytes, where each code point is represented by eight bytes of graphic information. At power-on, this vector is initialized to 000:0, and it is the responsibility of the user to change this vector if additional code points are required.

Interrupt Hex 40 - Reserved

When an IBM Fixed Disk Adapter is installed, the BIOS routines use interrupt hex 30 to revector the diskette pointer.

Interrupt Hex 41 - Fixed Disk Parameters

This vector points to a data region containing the parameters required for the fixed disk drive. The power-on routines initialize the vector to point to the parameters contained in the ROM disk routine. These default parameters represent the specified values for any IBM fixed disk drives attached to the system. Changing this parameter block may be necessary to reflect the specifications of the other fixed disk drives attached.

Other Read/Write Memory Usage

The IBM BIOS routines use 256 bytes of memory from absolute hex 400 to hex 4FF. Locations hex 400 to 407 contain the base addresses of any RS-232C cards attached to the system. Locations hex 408 to 40F contain the base addresses of the Printer Adapter.

Memory locations hex 300 to 3FF are used as a stack area during the power-on initialization, and bootstrap when control is passed to it from power-on. If the user desires the stack in a different area, the area must be set by the application.

Address (Hex)	Interrupt (Hex)	Function

BIOS Programming Hints

The BIOS code is invoked through software interrupts. The programmer should not "hard code" BIOS addresses into application programs. The internal workings and absolute addresses within BIOS are subject to change without notice.

If an error is reported by the disk or diskette code, you should reset the drive adapter and retry the operation. A specified number of retries should be required on diskette reads to ensure the problem is not due to motor start-up.

When altering I/O-port bit values, the programmer should change only those bits that are necessary to the current task. Upon completion, the programmer should restore the original environment. Failure to adhere to this practice may be incompatible with present and future applications.

Adapter Cards with System-Accessible ROM Modules

The ROM BIOS provides a facility to integrate adapter cards with on-board ROM code into the system. During the POST, interrupt vectors are established for the BIOS calls. After the default vectors are in place, a scan for additional ROM modules takes place. At this point, a ROM routine on the adapter card may gain control. The routine may establish or intercept interrupt vectors to hook themselves into the system.

The absolute addresses hex C8000 through hex F4000 are scanned in 2K blocks in search of a valid adapter card ROM. A valid ROM is defined as follows:

Byte 0: Hex 55 Byte 1: Hex AA

Byte 2: A length indicator representing the number of

512-byte blocks in the ROM (length/512). A checksum is also done to test the integrity of the ROM module. Each byte in the defined ROM is summed modulo hex 100. This sum must be 0 for the

module to be deemed valid.

When the POST identifies a valid ROM, it does a far call to byte 3 of the ROM (which should be executable code). The adapter card may now perform its power-on initialization tasks. The feature ROM should return control to the BIOS routines by executing a far return.

Keyboard Encoding and Usage

Encoding

The keyboard routine provided by IBM in the ROM BIOS is responsible for converting the keyboard scan codes into what will be termed "Extended ASCII."

Extended ASCII encompasses one-byte character codes with possible values of 0 to 255, an extended code for certain extended keyboard functions, and functions handled within the keyboard routine or through interrupts.

Character Codes

The following character codes are passed through the BIOS keyboard routine to the system or application program. A '-1' means the combination is suppressed in the keyboard routine. The codes are returned in AL.

Key Number	Base Case	Upper Case	Ctrl	Alt
1	Esc	Esc	Esc	- 1
2	1	!	– 1	Note 1
3	2	@	Nul (000) Note 1	Note 1

70	– 1	– 1	Break (Note 2)	- 1
Scroll Lock				

Notes: 1. Refer to "Extended Codes" in this section.

2. Refer to "Special Handling" in this section.

Character Codes (Part 3 of 3)

Keys 71 through 83 have meaning only in base case, in Num Lock (or shifted) states, or in Ctrl state. Note that the Shift key temporarily reverses the current Num Lock state.

Key Number	Num Lock	Base Case	Alt	Ctrl
71	7	Home (Note 1)	- 1	Clear Screen
72	8	(Note 1)	- 1	– 1
73	9	Page Up (Note 1)	- 1	Top of Text and Home
74	-		- 1	– 1
75	4	(Note 1)	– 1	Reverse Word (Note 1)
76	5	- 1	- 1	– 1
77	6	——→(Note 1)	– 1	Advance Word (Note 1)
78	+	+	– 1	– 1
79	1	End (Note 1)	– 1	Erase to EOL (Note 1)
80	2	(Note 1)	- 1	– 1
81	3	Page Down (Note 1)	- 1	Erase to EOS (Note 1)
82	0	Ins	- 1	– 1
83		Del (Notes 1,2)	Note 2	Note 2

Notes: 1. Refer to "Extended Codes" in this section.

2. Refer to "Special Handling" in this section.

Extended Codes

Extended Functions

For certain functions that cannot be represented in the standard ASCII code, an extended code is used. A character code of 000 (Nul) is returned in AL. This indicates that the system or application program should examine a second code that will indicate the actual function. Usually, but not always, this second code is the scan code of the primary key that was pressed. This code is returned in AH.

Second Code	Function
3	Nul Character
15	←
16-25	Alt Q, W, E, R, T, Y, U, I, O, P
30-38	Alt A, S, D, F, G, H, J, K, L
44-50	Alt Z, X, C, V, B, N, M
59-68	F1 to F10 Function Keys Base Case
71	Home
72	†
73	Page Up and Home Cursor
75	<u></u>
77	
79	End
80	↓
81	Page Down and Home Cursor
82	Ins (Insert)
83	Del (Delete)
84-93	F11 to F20 (Uppercase F1 to F10)
94-103	F21 to F30 (Ctrl F1 to F10)
104-113	F31 to F40 (Alt F1 to F10)
114	Ctrl PrtSc (Start/Stop Echo to Printer)
115	Ctrl
116	Ctrl—►(Advance Word)
117	Ctrl End [Erase to End of Line (EOL)]
118	Ctrl PgDn [Erase to End of Screen (EOS)]
119	Ctrl Home (Clear Screen and Home)
120-131	Alt 1, 2, 3, 4, 5, 6, 7, 8, 9, 0, -, = (Keys 2-13)
132	Ctrl PgUp (Top 25 Lines of Text and Home Cursor)

Keyboard Extended Functions

Shift States

Most shift states are handled within the keyboard routine, transparent to the system or application program. In any case, the current set of active shift states is available by calling an entry point in the ROM keyboard routine. The key numbers are shown on the keyboard diagram in Section 4. The following keys result in altered shift states:

Shift

This key temporarily shifts keys 2–13, 15–27, 30–41, 43–53, 55, 59–68 to uppercase (base case if in Caps Lock state). Also, the Shift key temporarily reverses the Num Lock or non-Num-Lock state of keys 71–73, 75, 77, and 79–83.

Ctrl

This key temporarily shifts keys 3, 7, 12, 14, 16–28, 30–38, 43–50, 55, 59–71, 73, 75, 77, 79, and 81 to the Ctrl state. Also, the Ctrl key is used with the Alt and Del keys to cause the system reset function, with the Scroll Lock key to cause the break function, and with the Num Lock key to cause the pause function. The system reset, break, and pause functions are described in "Special Handling" on the following pages.

Alt

This key temporarily shifts keys 2-13, 16-25, 30-38, 44-50, and 59-68 to the Alt state. Also, the Alt key is used with the Ctrl and Del keys to cause the "system reset" function described in "Special Handling" on the following pages.

The Alt key has another use. This key allows the user to enter any ASCII character code from 0 to 255 into the system from the keyboard. The user holds down the Alt key and types the decimal value of the characters desired using the numeric keypad (keys 71–73, 75–77, and 79–82). The Alt key is then released. If more than three digits are typed, a modulo-256 result is created. These

three digits are interpreted as a character code and are transmitted through the keyboard routine to the system or application program. Alt is handled within the keyboard routine.

Caps Lock

This key shifts keys 16–25, 30–38, and 44–50 to uppercase. Pressing the Caps Lock key a second time reverses the action. Caps Lock is handled within the keyboard routine.

Scroll Lock

This key is interpreted by appropriate application programs as indicating that use of the cursor-control keys should cause windowing over the text rather than cursor movement. Pressing the Scroll Lock key a second time reverses the action. The keyboard routine simply records the current shift state of the Scroll Lock key. It is the responsibility of the system or application program to perform the function.

Shift Key Priorities and Combinations

If combinations of the Alt, Ctrl, and Shift keys are pressed and only one is valid, the precedence is as follows: the Alt key is first, the Ctrl key is second, and the Shift key is third. The only valid combination is Alt and Ctrl, which is used in the system reset function.

Special Handling

System Reset

The combination of the Alt, Ctrl, and Del keys will result in the keyboard routine initiating the equivalent of a system reset. System reset is handled within the keyboard routine.

Break

The combination of the Ctrl and Break keys will result in the keyboard routine signaling interrupt hex 1A. Also the extended characters (AL = hex 00, AH = hex 00) will be returned.

Pause

The combination of the Ctrl and Num Lock keys will cause the keyboard interrupt routine to loop, waiting for any key except the Num Lock key to be pressed. This provides a system- or application-transparent method of temporarily suspending list, print, and so on, and then resuming the operation. The "unpause" key is thrown away. Pause is handled within the keyboard routine.

Print Screen

The combination of the Shift and PrtSc (key 55) keys will result in an interrupt invoking the print screen routine. This routine works in the alphanumeric or graphics mode, with unrecognizable characters printing as blanks.

Extended Functions

The keyboard routine does its own buffering. The keyboard buffer is large enough that few typists will ever fill it. However, if a key is pressed when the buffer is full, the key will be ignored and the "bell" will sound.

Also, the keyboard routine suppresses the typematic action of the following keys: Ctrl, Shift, Alt, Num Lock, Scroll Lock, Caps Lock, and Ins.

Keyboard Usage

This section is intended to outline a set of guidelines of key usage when performing commonly used functions.

Function	Key(s)	Comment
Home Cursor	Home	Editors; word processors
Return to outermost menu	Home	Menu driven applications
Move cursor up	1	Full screen editor, word processor
Page up, scroll backward 25 lines and home	PgUp	Editors; word processors
Move cursor left	← Key 75	Text, command entry
Move cursor right	→	Text, command entry
Scroll to end of text Place cursor at end of line	End	Editors; word processors
Move cursor down	+	Full screen editor, word processor
Page down, scroll forward 25 lines and home	Pg Dn	Editors; word processors
Start/Stop insert text at cursor, shift text right in buffer	Ins	Text, command entry
Delete character at cursor	Del	Text, command entry
Destructive backspace	← Key 14	Text, command entry
Tab forward	→	Text entry
Tab reverse	+	Text entry
Clear screen and home	Ctrl Home	Command entry
Scroll up	1	In scroll lock mode
Scroll down	+	In scroll lock mode
Scroll left	+	In scroll lock mode
Scroll right	→	In scroll lock mode
Delete from cursor to EOL	Ctrl End	Text, command entry
Exit/Escape	Esc	Editor, 1 level of menu, and so on
Start/Stop Echo screen to printer	Ctrl Prt Sc (Key 55)	Any time
Delete from cursor to EOS	Ctrl PgDn	Text, command entry
Advance word	Ctrl ->	Text entry
Reverse word	Ctrl ←	Text entry
Window Right	Ctrl ->	When text is too wide to fit screen
Window Left	Ctrl ←	When text is too wide to fit screen
Enter insert mode	Ins	Line editor

Keyboard - Commonly Used Functions (Part 1 of 2)

5-22 System BIOS

Function	Key(s)	Comment
Exit insert mode	Ins	Line editor
Cancel current line	Esc	Command entry, text entry
Suspend system (pause)	Ctrl Num Lock	Stop list, stop program, and so on Resumes on any key
Break interrupt	Ctrl Break	Interrupt current process
System reset	Alt Ctrl Del	Reboot
Top of document and home cursor	Ctrl PgUp	Editors, word processors
Standard function keys	F1-F10	Primary function keys
Secondary function keys	Shift F1-F10 Ctrl F1-F10 Alt F1-F10	Extra function keys if 10 are not sufficient
Extra function keys	Alt Keys 2-13 (1-9,0,-,=)	Used when templates are put along top of keyboard
Extra function keys	Alt A-Z	Used when function starts with same letter as one of the alpha keys

Keyboard - Commonly Used Functions (Part 2 of 2)

Function	Key
Carriage return	—
Line feed	Ctrl ←
Bell	Ctrl G
Home	Home
Cursor up	l i t
Cursor down	♦'
Cursor left	←
Cursor right	→
Advance one word	Ctrl -
Reverse one word	Ctrl ←
Insert	Ins
Delete	Del
Clear screen	Ctrl Home
Freeze output	Ctrl Num Lock
Tab advance	→
Stop execution (break)	Ctrl Break
Delete current line	Esc
Delete to end of line	Ctrl End
Position cursor to end of line	End

BASIC Screen Editor Special Functions

Function	Key
Suspend	Ctrl Num Lock
Echo to printer	Ctrl PrtSc
	(Key 55 any case)
Stop echo to printer	Ctrl PrtSc
	(Key 55 any case)
Exit current function (break)	Ctrl
·	Break
Backspace	← Key 14
Line feed	Ctrl←
Cancel line	Esc
Copy character	F1 or →
Copy until match	F2
Copy remaining	F3
Skip character	Del
Skip until match	F4
Enter insert mode	Ins
Exit insert mode	Ins
Make new line the template	F5
String separator in REPLACE	F6
End of file in keyboard input	F6

DOS Special Functions

5-24 System BIOS

BIOS Cassette Logic

Software Algorithms - Interrupt Hex 15

The cassette routine is called by the request type in AH. The address of the bytes to be read from or written to the tape is specified ES:BX and the number of bytes to be read or written is specified by CX. The number of bytes read is returned in DX. The read block and write block automatically turn the cassette motor on at the start and off at the end. The request types in AH and the cassette status descriptions follow:

Request Type	Function
AH = 0	Turn Cassette Motor On
AH = 1	Turn Cassette Motor Off
AH = 2	Read Tape Block
	Read CX bytes into memory starting at Address ES:BX
	Return actual number of bytes read in DX
	Return Cassette Status in AH
AH = 3	Write Tape Block
	Write CX bytes onto cassette starting at Address DS:BX
	Return Cassette Status in AH

Cassette Status	Description	
AH = 00	No Errors	
AH = 01	Cyclic Redundancy Check (CRC) Error in Read Block	
AH = 02	No Data Transitions	
AH = 04	No Leader	
AH = 80	Invalid Command	
Notes: The carry flag will be set on any error.		

Cassette Write

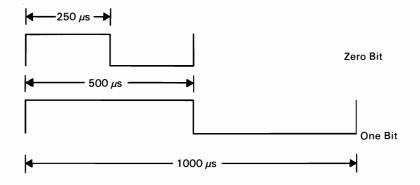

The write-block routine writes a tape block onto the cassette tape. The tape block is described in "Data Record Architecture" later in this section.

The write-block routine turns on the cassette drive motor and a synchronization bit(0) and then writes the leader(256 bytes of all 1's) to the tape. Next, the routine writes the number of data

blocks specified by CX. After each data block of 256 bytes, a 2-byte cyclic redundancy check (CRC) is written. The data bytes are taken from the memory location pointed at by ES.

The write-byte routine disassembles and writes the byte a bit at a time to the cassette. The method used is to set Timer 2 to the period of the desired data bit. The timer is set to a period of 1.0-ms for a 1 bit and 0.5-ms for a 0 bit.

The timer is set to mode 3, which means the timer outputs a square wave with a period given by its count register. The timer's period is changed on the fly for each data bit written to the cassette. If the number of data bytes to be written is not an integral multiple of 256, then, after the last desired data byte from memory has been written, the data block is extended to 256 bytes of writing multiples of the last data byte. The last block is closed with two CRC bytes as usual. After the last data block, a trailer consisting of four bytes of all 1 bits is written. Finally, the cassette motor is turned off, if there are no errors reported by the routine.

Cassette Read

The read-block routine turns on the cassette drive motor and then delays for about 0.5 second to allow the motor to come up to speed.

The read-block routine then searches for the leader and must detect all 1 bits for approximately 1/4 of the leader length before it can look for the sync (0) bit. After the sync bit is detected, the

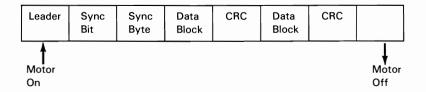

sync byte (ASCII character hex 16) is read. If the sync byte is read correctly, the data portion can be read. If a correct sync byte is not found, the routine goes back and searches for the leader again. The data is read a bit at a time and assembled into bytes. After each byte is assembled, it is written into memory at location ES:BX and BX is incremented by 1.

After each multiple of 256 data bytes is read, the CRC is read and compared to the CRC generated. If a CRC error is detected, the routine exits with the carry flag set to indicate an error and the status of AH set to hex 01. DX contains the number of bytes written to memory.

The time of day interrupt(IRQ0) is disabled during the cassette-read operation.

Data Record Architecture

The write-block routine uses the following format to record a tape block onto a cassette tape.

Component	Description
Leader	256 Bytes (of All 1's)
Sync Bit	One O Bit
Sync Byte	ASCII Character Hex 16
Data Blocks	256 Bytes in Length
CRC	2 Bytes for each Data Block

Data Record Components

Error Recovery

Error recovery is handled through software. A CRC is used to detect errors. The polynomial used is $G(X) = X^{16} + X^{12} + X^5 + 1$, which is the polynomial used by the synchronous data link control interface. Essentially, as bits are written to or read from the cassette tape, they are passed through the CRC register in software. After a block of data is written, the complemented value of the calculated CRC register is written on the tape. On reading the cassette data, the CRC bytes are read and compared to the generated CRC value. If the read CRC does not equal the generated CRC, the processor's carry flag is set and the status of AH is set to hex 01, which indicates a CRC error has occurred. The routine is exited on a CRC error.

l	FLAGSH	FLAGSL	Status Flags	
ĺ	C	s	Code Segment]
	D	S	Data Segment	Segment
	S	S	Stack Segment	Register File
	E	S	Extra Segment	

Instructions which reference the flag register file as a 16-bit object use the symbol FLAGS to represent the file:

x = Don't Care

Operand Summary

"reg field Bit Assignments:

16-Bit	[w = 1]	8-Bit [v	w = 0]	Segr	nent
000	AX	000	AL	00	ES
001	CX	001	CL	01	CS
010	DX	010	DL	10	SS
011	BX	011	BL	11	DS
100	SP	100	ΑH		
101	BP	101	СН		
110	SI	110	DH		
111	DI	111	BH		

Second Instruction Byte Summary

mod	xxx	r/m
-----	-----	-----

mod	Displacement
00	DISP = 0*, disp-low and disp-high are absent
01	DISP = disp-low sign-extended to 16-bits, disp-high is absent
10	DISP = disp-high: disp-low
11	r/m is treated as a "reg" field

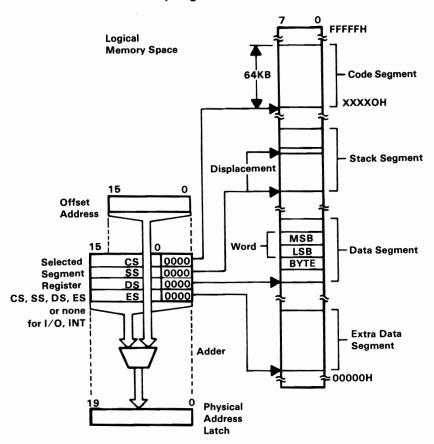

MF = Memory format	r/m	Operand Address
00 - 32-bit Real	000	(BX) + (SI) + DISP
01 — 32-bit Integer	001	(BX) + (DI) + DISP
10 — 64-bit Real	010	(BP) + (SI) + DISP
11 — 64-bit Integer	011	(BP) + (DI) + DISP
	100	(SI) + DISP
	101	(DI) + DISP
	110	(BP) + DISP*
	111	(BX) + DISP

DISP follows 2nd byte of instruction (before data if required).

6-4 Instruction Set

^{*}except if mod = 00 and r/m = 110 then EA = disp-high: disp-low.

Memory Segmentation Model

Segment Override Prefix

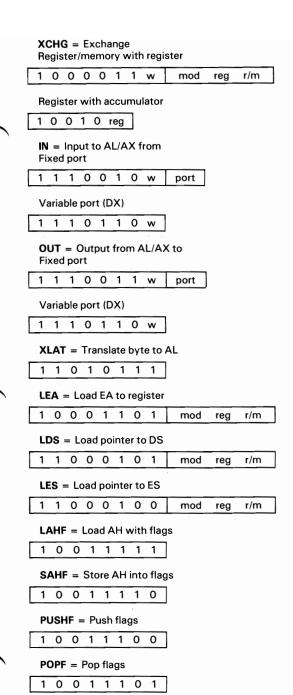

0 0 1 reg 1 1 0

Use of Segment Override

Operand Register	Default	With Override Prefix
IP (Code Address)	cs	Never
SP (Stack Address)	SS	Never

8088 Conditional Transfer Operations

Instruction	Condition	Interpretation
JE or JZ	ZF = 1	"equal" or "zero"
JL or JNGE	$(SF \times OF) = 1$	"less" or "not greater or equal"
JLE or JNG	((SF xor OF) or	''less or equal'' or ''not greater''
	ZF) = 1	*
JB or JNAE or JC	CF = 1	"below" or "not above or equal"
JBE or JNA	(CF or ZF) = 1	"below or equal" or "not above"
JP or JPE	PF = 1	"parity" or "parity even"
JO	OF = 1	"overflow"
JS	SF = 1	''sign''
JNE or JNZ	ZF = 0	"not equal" or "not zero"
JNL or JGE	$(SF \times OF) = 0$	"not less" or "greater or equal"
JNLE or JG	((SF xor OF) or	"not less or equal" or "greater"
	ZF) = 0	·
JNB or JAE or JNC	CF = 0	"not below" or "above or equal"
JNBE or JA	(CF or ZF) = 0	"not less or equal" or "above"
JNP or JPO	PF = 0	"not parity" or "parity odd"
JNO	OF = 0	"not overflow"
JNS	SF = 0	"not sign"

^{*&#}x27;'Above'' and ''below'' refer to the relation between two unsigned values, while ''greater'' and ''less'' refer to the relation between two signed values.

INT = Interrupt Type specified

١						_			
	1	1	Λ	Λ	1	1	^	1	type
ı			U	U			U		type

Type 3

INTO = Interrupt on overflow

IRET = Interrupt return

Processor Control

CLC = Clear carry

STC = Set carry

1 1 1 1 1 0 0 0

1 1 1 1 1 0 0 1

CMC = Complement carry

NOP = No operation

1 1 1 1 0 1 0 1

1 0 0 1 0 0 0 0

CLD = Clear direction

STD = Set direction

1 1 1 1 1 0 0

1 1 1 1 1 1 0 1

CLI = Clear interrupt

STI = Set interrupt

1 1 1 1 1 0 1 0

1 1 1 1 1 0 1 1

HLT = Halt

WAIT = Wait

1 1 1 1 0 1 0 0

1 0 0 1 1 0 1 1

LOCK = Bus lock prefix

ESC = Escape (to external device)

1 1 1 1 0 0 0 0

1 1 0 1 1 x x x mod x x x r/m

Footnotes:

if d = 1 then "to"; if d = 0 then "from"

if w = 1 then word instruction; if w = 0 then byte instruction

if s:w = 01 then 16 bits of immediate data from the operand

if s:w = 11 then an immediate data byte is signed extended to form the 16-bit operand

if v = 0 then "count" = 1; if v = 1 then "count" in (CL)

x = don't care

z is used for some string primitives to compare with ZF FLAG

AL = 8-bit accumulator

AX = 16-bit accumulator

CX = Count register

DS = Data segment

DX = Variable port register

ES = Extra segment

Above/below refers to unsigned value

Greater = more positive;

Less = less positive (more negative) signed values

8087 Extensions to the 8088 Instruction Set

- NOTE 1 Asterisk (*) can easily be keyed using two methods:

 1) hit the Prt Sc key or 2) in shift mode hit the

 * key.
- NOTE 2 Period (.) can easily be keyed using two methods:

 1) hit the key or 2) in shift or Num Lock
 mode hit the believe.
- NOTE 3 Numeric characters (0—9) can easily be keyed using two methods: 1) hit the numeric keys on the top row of the typewriter portion of the keyboard or 2) in shift or Num Lock mode hit the numeric keys in the 10—key pad portion of the keyboard.
- NOTE 4 Upper case alphabetic characters (A—Z) can easily be keyed in two modes: 1) in shift mode the appropriate alphabetic key or 2) in Caps Lock mode hit the appropriate alphabetic key.
- NOTE 5 Lower case alphabetic characters (a—z) can easily be keyed in two modes: 1) in "normal" mode hit the appropriate key or 2) in Caps Lock combined with shift mode hit the appropriate alphabetic key.
- NOTE 6 The 3 digits after the Alt key must be typed from the numeric key pad (keys 71—73, 75—77, 79—82). Character codes 000 through 255 can be entered in this fashion. (With Caps Lock activated, Character codes 97 through 122 will display upper case rather than lower case alphabetic characters.)

SECTION 8. COMMUNICATIONS

Co	4		4
	nt	Δn	TC
\mathbf{v}			

Communications	8-3
Establishing a Communications Link	8-5
Establishing Link on Nonswitched Point-to-Point Line	8-6
Establishing Link on Nonswitched Multipoint Line	8-8
Establishing Link on Switched Point-to-Point Line	8-10

Information processing equipment used for communications is called data terminal equipment (DTE). Equipment used to connect the DTE to the communications line is called data communications equipment (DCE).

An adapter is used to connect the data terminal equipment to the data communications line as shown in the following illustration:

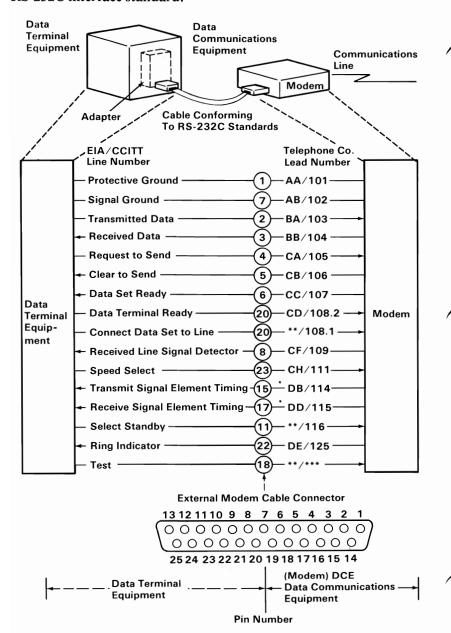

The EIA/ CCITT adapter allows data terminal equipment to be connected to data communications equipment using EIA or CCITT standardized connections. An external modem is shown in this example; however, other types of data communications equipment can also be connected to data terminal equipment using EIA or CCITT standardized connections.

EIA standards are labeled RS-x (Recommended Standards-x) and CCITT standards are labeled V.x or X.x, where x is the number of the standard.

The EIA RS-232 interface standard defines the connector type, pin numbers, line names, and signal levels used to connect data terminal equipment to data communications equipment for the purpose of transmitting and receiving data. Since the RS-232 standard was developed, it has been revised three times. The three revised standards are the RS-232A, the RS-232B, and the presently used RS-232C.

The CCITT V.24 interface standard is equivalent to the RS-232C standard; therefore, the descriptions of the EIA standards also apply to the CCITT standards.

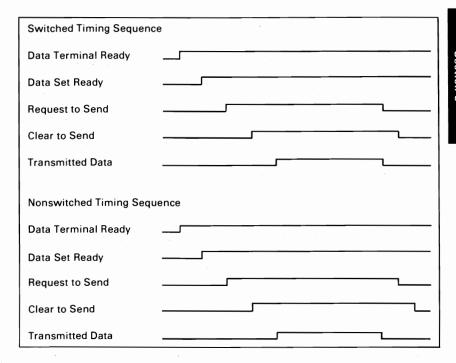

The following is an illustration of data terminal equipment connected to an external modem using connections defined by the RS-232C interface standard:

- * Not used when business machine clocking is used.
- * * Not standardized by EIA (Electronic Industries Association).
- * * * Not standardized by CCITT

Establishing a Communications Link

The following bar graphs represent normal timing sequences of operation during the establishment of communications for both switched (dial-up) and nonswitched (direct line) networks.

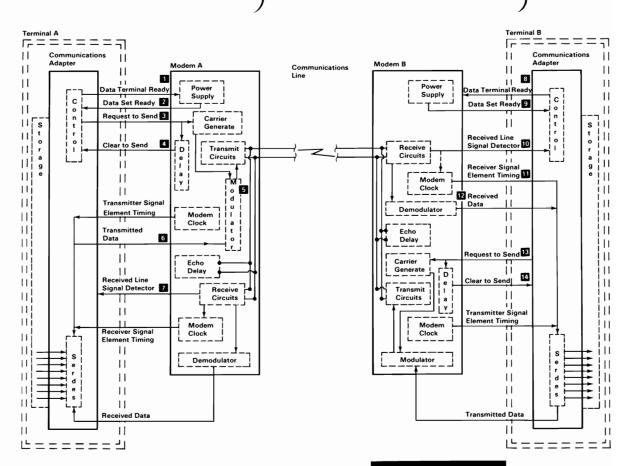

The following examples show how a link is established on a nonswitched point-to-point line, a nonswitched multipoint line, and a switched point-to-point line.

Establishing a Link on a Nonswitched Point-to-Point Line

- The terminals at both locations activate the 'data terminal ready' lines 1 and 8.
- Normally the 'data set ready' lines 2 and 9 from the modems are active whenever the modems are powered on.
- Terminal A activates the 'request to send' line, which causes the modem at terminal A to generate a carrier signal.
- 4. Modem B detects the carrier, and activates the 'received line signal detector' line (sometimes called data carrier detect). Modem B also activates the 'receiver signal element timing' line (sometimes called receive clock) to send receive clock signals to the terminal. Some modems activate the clock signals whenever the modem is powered on.
- After a specified delay, modem A activates the 'clear to send' line 4 which indicates to terminal A that the modem is ready to transmit data.
- Terminal A serializes the data to be transmitted (through the serdes) and transmits the data one bit at a time (synchronized by the transmit clock) onto the 'transmitted data' line to the modem.
- 7. The modem modulates the carrier signal with the data and transmits it to the modem B 5.
- 8. Modem B demodulates the data from the carrier signal and sends it to terminal B on the 'received data' line 12.
- Terminal B deserializes the data (through the serdes) using the receive clock signals (on the 'receiver signal element timing' line) 11 from the modem.
- After terminal A completes its transmission, it deactivates the 'request to send' line 3, which causes the modem to turn off the carrier and deactivate the 'clear to send' line 4.

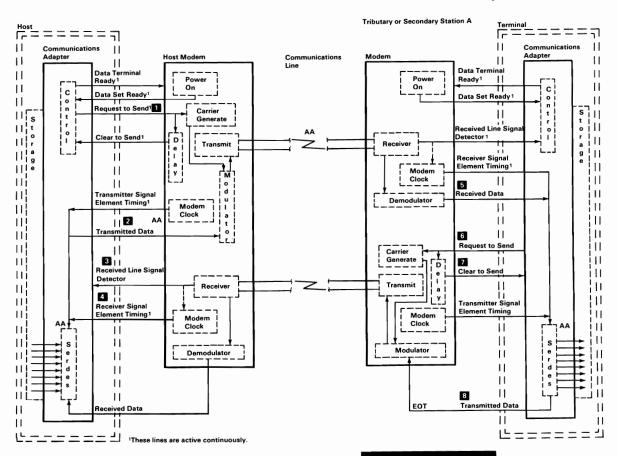

- 11. Terminal A and modem A now become receivers and wait for a response from terminal B, indicating that all data has reached terminal B. Modem A begins an echo delay (50 to 150 milliseconds) to ensure that all echoes on the line have diminished before it begins receiving. An echo is a reflection of the transmitted signal. If the transmitting modem changed to receive too soon, it could receive a reflection (echo) of the signal it just transmitted.
- 12. Modem B deactivates the 'received line signal detector' line 10 and, if necessary, deactivates the receive clock signals on the 'receiver signal element timing, line 11.
- 13. Terminal B now becomes the transmitter to respond to the request from terminal A. To transmit data, terminal B activates the 'request to send' line 13, which causes modem B to transmit a carrier to modem A.
- 14. Modem B begins a delay that is longer than the echo delay at modem A before turning on the 'clear to send' line. The longer delay (called request-to-send delay) ensures that modem A is ready to receive when terminal B begins transmitting data. After the delay, modem B activates the 'clear to send' line 14 to indicate that terminal B can begin transmitting its response.
- 15. After the echo delay at modem A, modem A senses the carrier from modem B (the carrier was activated in step 13 when terminal B activated the 'request to send' line) and activates the 'received line signal detector; line 7 to terminal A.
- 16. Modem A and terminal A are ready to receive the response from termianl B. Remember, the response was not transmitted until after the request-to-send to clear-to-send delay at modem B (step 14).

Establishing a Link on a Nonswitched Multipoint Line

- The control station serializes the address for the tributary or secondary station (AA) and sends its address to the modem on the 'transmitted data' line 2.
- Since the 'request to send' line and, therefore, the modem carrier, is active continuously 1, the modem immediately modulates the carrier with the address, and, thus, the address is transmitted to all modems on the line.
- All tributary modems, including the modem for station A, demodulate the address and send it to their terminals on the 'received data' line 5.
- 4. Only station A responds to the address; the other stations ignore the address and continue monitoring their 'received data' line. To respond to the poll, station A activates its 'request to send' line 6, which causes the modem to begin transmitting a carrier signal.
- 5. The control station's modem receives the carrier and activates the 'received line signal detector' line 3 and the 'receiver signal element timing' line 4 (to send clock signals to the control station). Some modems activate the clock signals as soon as they are powered on.

- After a short delay to allow the control station modem to receive the carrier, the tributary modem activates the 'clear to send' line 7.
- 7. When station A detects the active 'clear to send' line, it transmits its response. (For this example, assume that station A has no data to send; therefore, it transmits an EOT 8.)
- After transmitting the EOT, station A deactivates the 'request to send' line 6. This causes the modem to deactivate the carrier and the 'clear to send' line 7.
- When the modem at the control station (host) detects the absence of the carrier, it deactivates the 'received line signal detector' line
- 10. Tributary station A is now in receive mode waiting for the next poll or select transmission from the control station.

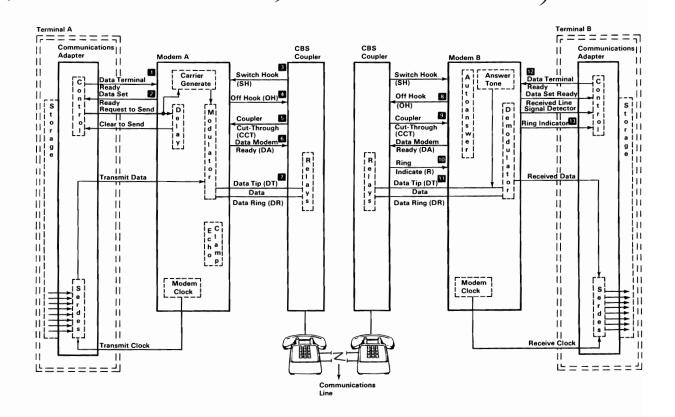

Establishing a Link on a Switched Point-To-Point Line

- Terminal A is in communications mode; therefore, the 'data terminal ready' line is active. Terminal B is in communication mode waiting for a call from terminal A.
- When the terminal A operator lifts the telephone handset, the 'switch hook' line from the coupler is activated
- Modem A detects the 'switch hook' line and activates the 'off hook' line 4, which causes the coupler to connect the telephone set to the line and activate the 'coupler cut-through' line 5 to the modem.
- Modem A activates the 'data modem ready' line to the coupler (the 'data modem ready' line is on continuously in some modems).
- The terminal A operator sets the exclusion key or talk/data switch to the talk position to connect the handset to the communications line. The operator then dials the terminal B number.
- 6. When the telephone at terminal B rings, the coupler activates the 'ring indicate' line to modem B 10. Modem B indicates that the 'ring indicate' line was activated by activating the 'ring indicator' line 13 to terminal B.
- Terminal B activates the 'data terminal ready' line to modem B 12
 which activates the autoanswer circuits in modem B. (The 'data
 terminal ready' line might already be active in some terminals.)

- The autoanswer circuits in modem B activate the 'off hook' line to the coupler
- The coupler connects modem B to the communications line through the 'data tip' and 'data ring' lines 11 and activates the 'coupler cutthrough' line 9 to the modem. Modem B then transmits an answer tone to terminal A.
- 10. The terminal A operator hears the tone and sets the exclusion key or talk/data switch to the data position (or performs an equivalent operation) to connect modem A to the communications line through the 'data tip' and 'data ring' lines
 7.
- 11. The coupler at terminal A deactivates the 'switch hook' line This causes modem A to activate the 'data set ready' line indicating to terminal A that the modem is connected to the communications line.

The sequence of the remaining steps to establish the data link is the same as the sequence required on a nonswitched point-to-point line. When the terminals have completed their transmission, they both deactivate the 'data terminal ready' line to disconnect the modems from the line.

Notes:

Glossary

- μ. Prefix micro; 0.000 001.
- μs. Microsecond; 0.000 001 second.
- A. Ampere.
- ac. Alternating current.

accumulator. A register in which the result of an operation is formed.

active high. Designates a signal that has to go high to produce an effect. Synonymous with positive true.

active low. Designates a signal that has to go low to produce an effect. Synonymous with negative true.

adapter. An auxiliary device or unit used to extend the operation of another system.

address bus. One or more conductors used to carry the binary-coded address from the processor throughout the rest of the system.

algorithm. A finite set of well-defined rules for the solution of a problem in a finite number of steps.

all points addressable (APA). A mode in which all points of a displayable image can be controlled by the user.

alphameric. Synonym for alphanumeric.

alphanumeric (A/N). Pertaining to a character set that contains letters, digits, and usually other characters, such as punctuation marks. Synonymous with alphameric.

alternating current (ac). A current that periodically reverses its direction of flow.

American National Standard Code for Information Exchange (ASCII). The standard code, using a coded character set consisting of 7-bit coded characters (8 bits including parity check), used for information exchange between data processing systems, data communication systems, and associated equipment. The ASCII set consists of control characters and graphic characters.

ampere (A). The basic unit of electric current.

A/N. Alphanumeric

analog. (1) Pertaining to data in the form of continuously variable physical quantities. (2) Contrast with digital.

AND. A logic operator having the property that if P is a statement, Q is a statement, R is a statement,..., then the AND of P, Q, R,...is true if all statements are true, false if any statement is false.

AND gate. A logic gate in which the output is 1 only if all inputs are 1.

AND operation. The boolean operation whose result has the boolean value 1, if and only if, each operand has the boolean value 1. Synonymous with conjunction.

APA. All points addressable.

ASCII. American National Standard Code for Information Exchange.

assemble. To translate a program expressed in an assembler language into a computer language.

assembler. A computer program used to assemble.

assembler language. A computer-oriented language whose instructions are usually in one-to-one correspondence with computer instructions.

asynchronous transmission. (1) Transmission in which the time of occurrence of the start of each character, or block of characters, is arbitrary; once started, the time of occurrence of each signal representing a bit within a character, or block, has the same relationship to significant instants of a fixed time frame. (2) Transmission in which each information character is individually transmitted (usually timed by the use of start elements and stop elements).

audio frequencies. Frequencies that can be heard by the human ear (approximately 15 hertz to 20 000 hertz).

auxiliary storage. (1) A storage device that is not main storage. (2) Data storage other than main storage; for example, storage on magnetic disk. (3) Contrast with main storage.

BASIC. Beginner's all-purpose symbolic instruction code.

basic input/output system (BIOS). The feature of the IBM Personal Computer that provides the level control of the major I/O devices, and relieves the programmer from concern about hardware device characteristics.

baud. (1) A unit of signaling speed equal to the number of discrete conditions or signal events per second. For example, one baud equals one bit per second in a train of binary signals, one-half dot cycle per second in Morse code, and one 3-bit value per second in a train of signals each of which can assume one of eight different states. (2) In asynchronous transmission, the unit of modulation rate corresponding to one unit of interval per second; that is, if the duration of the unit interval is 20 milliseconds, the modulation rate is 50 baud.

BCC. Block-check character.

beginner's all-purpose symbolic instruction code (BASIC). A programming language with a small repertoire of commands and a simple syntax, primarily designed for numeric applications.

binary. (1) Pertaining to a selection, choice, or condition that has two possible values or states. (2) Pertaining to a fixed radix numeration system having a radix of 2.

binary digit. (1) In binary notation, either of the characters 0 or 1. (2) Synonymous with bit.

binary notation. Any notation that uses two different characters, usually the binary digits 0 and 1.

binary synchronous communications (BSC). A uniform procedure, using a standardized set of control characters and control character sequences for synchronous transmission of binary—coded data between stations.

BIOS. Basic input/output system.

bit. Synonym for binary digit

bits per second (bps). A unit of measurement representing the number of discrete binary digits transmitted by a device in one second.

block. (1) A string of records, a string of words, or a character string formed for technical or logic reasons to be treated as an entity. (2) A set of things, such as words, characters, or digits, treated as a unit.

block-check character (BCC). In cyclic redundancy checking, a character that is transmitted by the sender after each message block and is compared with a block-check character computed by the receiver to determine if the transmission was successful.

boolean operation. (1) Any operation in which each of the operands and the result take one of two values. (2) An operation that follows the rules of boolean algebra.

bootstrap. A technique or device designed to bring itself into a desired state by means of its own action; for example, a machine routine whose first few instructions are sufficient to bring the rest of itself into the computer from an input device.

bps. Bits per second.

BSC. Binary synchronous communications.

buffer. (1) An area of storage that is temporarily reserved for use in performing an input/output operation, into which data is read or from which data is written. Synonymous with I/O area. (2) A portion of storage for temporarily holding input or output data.

bus. One or more conductors used for transmitting signals or power.

byte. (1) A sequence of eight adjacent binary digits that are operated upon as a unit. (2) A binary character operated upon as a unit. (3) The representation of a character.

C. Celsius.

capacitor. An electronic circuit component that stores an electric charge.

CAS. Column address strobe.

cathode ray tube (CRT). A vacuum tube in which a stream of electrons is projected onto a fluorescent screen producing a luminous spot. The location of the spot can be controlled.

cathode ray tube display (CRT display). (1) A CRT used for displaying data. For example, the electron beam can be controlled to form alphanumeric data by use of a dot matrix. (2) The data display produced by the device as in (1).

CCITT. International Telegraph and Telephone Consultative Committee.

Celsius (C). A temperature scale. Contrast with Fahrenheit (F).

central processing unit (CPU). Term for processing unit.

channel. A path along which signals can be sent; for example, data channel, output channel.

character generator. (1) In computer graphics, a functional unit that converts the coded representation of a graphic character into the shape of the character for display. (2) In word processing, the means within equipment for generating visual characters or symbols from coded data.

character set. (1) A finite set of different characters upon which agreement has been reached and that is considered complete for some purpose. (2) A set of unique representations called characters. (3) A defined collection of characters.

characters per second (cps). A standard unit of measurement for the speed at which a printer prints.

check key. A group of characters, derived from and appended to a data item, that can be used to detect errors in the data item during processing.

closed circuit. A continuous unbroken circuit; that is, one in which current can flow. Contrast with open circuit.

CMOS. Complementary metal oxide semiconductor.

code. (1) A set of unambiguous rules specifying the manner in which data may be represented in a discrete form. Synonymous with coding scheme. (2) A set of items, such as abbreviations, representing the members of another set. (3) To represent data or a computer program in a symbolic form that can be accepted by a data processor. (4) Loosely, one or more computer programs, or part of a computer program.

coding scheme. Synonym for code.

collector. An element in a transistor toward which current flows.

column address strobe (CAS). A signal that latches the column addresses in a memory chip.

compile. (1) To translate a computer program expressed in a problem-oriented language into a computer-oriented language. (2) To prepare a machine-language program from a computer program written in another programming language by making use of the overall logic structure of the program, or generating more than one computer instruction for each symbolic statement, or both, as well as performing the function of an assembler.

complementary metal oxide semiconductor (CMOS). A logic circuit family that uses very little power. It works with a wide range of power supply voltages.

computer. A functional unit that can perform substantial computation, including numerous arithmetic operations or logic operations, without intervention by a human operator during a run.

computer instruction code. A code used to represent the instructions in an instruction set. Synonymous with machine code.

computer program. A sequence of instructions suitable for processing by a computer.

computer word. A word stored in one computer location and capable of being treated as a unit.

configuration. (1) The arrangement of a computer system or network as defined by the nature, number, and the chief characteristics of its functional units. More specifically, the term configuration may refer to a hardware configuration or a software configuration. (2) The devices and programs that make up a system, subsystem, or network.

conjunction. Synonym for AND operation.

contiguous. Touching or joining at the edge or boundary; adjacent.

control character. A character whose occurrence in a particular context initiates, modifies, or stops a control operation.

control operation. An action that affects the recording, processing, transmission, or interpretation of data; for example, starting or stopping a process, carriage return, font change, rewind, and end of transmission.

control storage. A portion of storage that contains microcode.

cps. Characters per second.

CPU. Central processing unit.

CRC. Cyclic redundancy check.

CRT. Cathode ray tube.

CRT display. Cathode ray tube display.

CTS. Clear to send. Associated with modem control.

cursor. (1) In computer graphics, a movable marker that is used to indicate a position on a display. (2) A displayed symbol that acts as a marker to help the user locate a point in text, in a system command, or in storage. (3) A movable spot of light on the screen of a display device, usually indicating where the next character is to be entered, replaced, or deleted.

cyclic redundancy check (CRC). (1) A redundancy check in which the check key is generated by a cyclic algorithm. (2) A system of error checking performed at both the sending and receiving station after a block-check character has been accumulated.

cylinder. (1) The set of all tracks with the same nominal distance from the axis about which the disk rotates. (2) The tracks of a disk storage device that can be accessed without repositioning the access mechanism.

daisy-chained cable. A type of cable that has two or more connectors attached in series.

data. (1) A representation of facts, concepts, or instructions in a formalized manner suitable for communication, interpretation, or processing by human or automatic means. (2) Any representations, such as characters or analog quantities, to which meaning is, or might be assigned.

data base. A collection of data that can be immediately accessed and operated upon by a data processing system for a specific purpose.

data processing system. A system that performs input, processing, storage, output, and control functions to accomplish a sequence of operations on data.

data transmission. Synonym for transmission.

dB. Decibel.

dBa. Adjusted decibels.

dc. Direct current.

debounce. An electronic means of overcoming the make/break bounce of switches to obtain one smooth change of signal level.

decibel. (1) A unit that expresses the ratio of two power levels on a logarithmic scale. (2) A unit for measuring relative power.

decoupling capacitor. A capacitor that provides a low impedance path to ground to prevent common coupling between circuits.

Deutsche Industrie Norm (DIN). (1) German Industrial Norm. (2) The committee that sets German dimension standards.

digit. (1) A graphic character that represents an integer; for example, one of the characters 0 to 9. (2) A symbol that

represents one of the non-negative integers smaller than the radix. For example, in decimal notation, a digit is one of the characters 0 to 9.

digital. (1) Pertaining to data in the form of digits. (2) Contrast with analog.

DIN. Deutsche Industrie Norm.

DIN connector. One of the connectors specified by the DIN committee.

DIP. Dual in-line package.

DIP switch. One of a set of small switches mounted in a dual in-line package.

direct current (dc). A current that always flows in one direction.

direct memory access (DMA). A method of transferring data between main storage and I/O devices that does not require processor intervention.

disable. To stop the operation of a circuit or device.

disabled. Pertaining to a state of a processing unit that prevents the occurrence of certain types of interruptions. Synonymous with masked.

disk. Loosely, a magnetic disk.

diskette. A thin, flexible magnetic disk and a semirigid protective jacket, in which the disk is permanently enclosed. Synonymous with flexible disk.

diskette drive. A device for storing data on and retrieving data from a diskette.

display. (1) A visual presentation of data. (2) A device for visual presentation of information on any temporary character imaging device. (3) To present data visually. (4) See cathode ray tube display.

display attribute. In computer graphics, a particular property that is assigned to all or part of a display; for example, low intensity, green color, blinking status.

DMA. Direct memory access.

dot matrix. (1) In computer graphics, a two-dimensional pattern of dots used for constructing a display image. This type of matrix can be used to represent characters by dots. (2) In word processing, a pattern of dots used to form characters. This term normally refers to a small section of a set of addressable points; for example, a representation of characters by dots.

dot printer. Synonym for matrix printer.

dot-matrix character generator. In computer graphics, a character generator that generates character images composed of dots.

DSR. Data set ready. Associated with modem control.

DTR. In the IBM Personal Computer, data terminal ready. Associated with modem control.

dual in-line package (DIP). A widely used container for an integrated circuit. DIPs have pins in two parallel rows. The pins are spaced 1/10 inch apart. See also DIP switch.

duplex. (1) In data communication, pertaining to a simultaneous two-way independent transmission in both directions. (2) Contrast with half-duplex.

duty cycle. In the operation of a device, the ratio of on time to idle time. Duty cycle is expressed as a decimal or percentage.

dynamic memory. RAM using transistors and capacitors as the memory elements. This memory requires a refresh (recharge) cycle every few milliseconds. Contrast with static memory.

EBCDIC. Extended binary-coded decimal interchange code.

ECC. Error checking and correction.

edge connector. A terminal block with a number of contacts attached to the edge of a printed-circuit board to facilitate plugging into a foundation circuit.

EIA. Electronic Industries Association.

electromagnet. Any device that exhibits magnetism only while an electric current flows through it.

enable. To initiate the operation of a circuit or device.

end of block (EOB). A code that marks the end of a block of data.

end of file (EOF). An internal label, immediately following the last record of a file, signaling the end of that file. It may include control totals for comparison with counts accumulated during processing.

end-of-text (ETX). A transmission control character used to terminate text.

end-of-transmission (EOT). A transmission control character used to indicate the conclusion of a transmission, which may have included one or more texts and any associated message headings.

end-of-transmission-block (ETB). A transmission control character used to indicate the end of a transmission block of data when data is divided into such blocks for transmission purposes.

EOB. End of block.

EOF. End of file.

EOT. End-of-transmission.

EPROM. Erasable programmable read-only memory.

erasable programmable read-only memory (EPROM). A PROM in which the user can erase old information and enter new information.

error checking and correction (ECC). The detection and correction of all single-bit errors, plus the detection of double-bit and some multiple-bit errors.

ESC. The escape character.

escape character (ESC). A code extension character used, in some cases, with one or more succeeding characters to indicate by some convention or agreement that the coded representations following the character or the group of characters are to be interpreted according to a different code or according to a different coded character set.

ETB. End-of-transmission-block.

ETX. End-of-text.

extended binary-coded decimal interchange code (EBCDIC). A set of 256 characters, each represented by eight bits.

F. Fahrenheit.

Fahrenheit (F). A temperature scale. Contrast with Celsius (C).

falling edge. Synonym for negative-going edge.

FCC. Federal Communications Commission.

fetch. To locate and load a quantity of data from storage.

FF. The form feed character.

field. (1) In a record, a specified area used for a particular category of data. (2) In a data base, the smallest unit of data that can be referred to.

fixed disk drive. In the IBM Personal Computer, a unit consisting of nonremovable magnetic disks, and a device for storing data on and retrieving data from the disks.

flag. (1) Any of various types of indicators used for identification. (2) A character that signals the occurrence of some condition, such as the end of a word. (3) Deprecated term for mark.

flexible disk. Synonym for diskette.

flip-flop. A circuit or device containing active elements, capable of assuming either one of two stable states at a given time.

font. A family or assortment of characters of a given size and style; for example, 10 point Press Roman medium.

foreground. (1) In multiprogramming, the environment in which high-priority programs are executed. (2) On a color display screen, the characters as opposed to the background.

form feed. (1) Paper movement used to bring an assigned part of a form to the printing position. (2) In word processing, a function that advances the typing position to the same character position on a predetermined line of the next form or page.

form feed character. A control character that causes the print or display position to move to the next predetermined first line on the next form, the next page, or the equivalent.

format. The arrangement or layout of data on a data medium.

frame. (1) In SDLC, the vehicle for every command, every response, and all information that is transmitted using SDLC procedures. Each frame begins and ends with a flag. (2) In data transmission, the sequence of contiguous bits bracketed by and including beginning and ending flag sequences.

g. Gram.

G. (1) Prefix giga; 1 000 000 000. (2) When referring to computer storage capacity, 1 073 741 824. (1 073 741 824 = 2 to the 30th power.)

gate. (1) A combinational logic circuit having one output channel and one or more input channels, such that the output channel state is completely determined by the input channel states. (2) A signal that enables the passage of other signals through a circuit.

Gb. 1 073 741 824 bytes.

general-purpose register. A register, usually explicitly addressable within a set of registers, that can be used for different purposes; for example, as an accumulator, as an index register, or as a special handler of data.

giga (G). Prefix 1 000 000 000.

gram (g). A unit of weight (equivalent to 0.035 ounces).

graphic. A symbol produced by a process such as handwriting, drawing, or printing.

graphic character. A character, other than a control character, that is normally represented by a graphic.

half-duplex. (1) In data communication, pertaining to an alternate, one way at a time, independent transmission. (2) Contrast with duplex.

hardware. (1) Physical equipment used in data processing, as opposed to programs, procedures, rules, and associated documentation. (2) Contrast with software.

head. A device that reads, writes, or erases data on a storage medium; for example, a small electromagnet used to read, write, or erase data on a magnetic disk.

hertz (Hz). A unit of frequency equal to one cycle per second.

hex. Common abbreviation for hexadecimal.

hexadecimal. (1) Pertaining to a selection, choice, or condition that has 16 possible different values or states. These values or states are usually symbolized by the ten digits 0 through 9 and the six letters A through F. (2) Pertaining to a fixed radix numeration system having a radix of 16.

high impedance state. A state in which the output of a device is effectively isolated from the circuit.

highlighting. In computer graphics, emphasizing a given display group by changing its attributes relative to other display groups in the same display field.

high-order position. The leftmost position in a string of characters. See also most-significant digit.

housekeeping. Operations or routines that do not contribute directly to the solution of the problem but do contribute directly to the operation of the computer.

Hz. Hertz

image. A fully processed unit of operational data that is ready to be transmitted to a remote unit; when loaded into control storage in the remote unit, the image determines the operations of the unit.

immediate instruction. An instruction that contains within itself an operand for the operation specified, rather than an address of the operand.

index register. A register whose contents may be used to modify an operand address during the execution of computer instructions.

indicator. (1) A device that may be set into a prescribed state, usually according to the result of a previous process or on the occurrence of a specified condition in the equipment, and that usually gives a visual or other indication of the existence of the prescribed state, and that may in some cases be used to determine the selection among alternative processes; for example, an overflow indicator. (2) An item of data that may be interrogated to determine whether a particular condition has been satisfied in the execution of a computer program; for example, a switch indicator, an overflow indicator.

inhibited. (1) Pertaining to a state of a processing unit in which certain types of interruptions are not allowed to occur. (2) Pertaining to the state in which a transmission control unit or an audio response unit cannot accept incoming calls on a line.

initialize. To set counters, switches, addresses, or contents of storage to 0 or other starting values at the beginning of, or at prescribed points in, the operation of a computer routine.

input/output (I/O). (1) Pertaining to a device or to a channel that may be involved in an input process, and, at a different time, in an output process. In the English language, "input/output" may be used in place of such terms as "input/output, data" "input/output signal," and "input/output terminals," when such usage is clear in a given context. (2) Pertaining to a device whose parts can be performing an input process and an output process at the same time. (3) Pertaining to either input or output, or both.

instruction. In a programming language, a meaningful expression that specifies one operation and identifies its operands, if any.

instruction set. The set of instructions of a computer, of a programming language, or of the programming languages in a programming system.

interface. A device that alters or converts actual electrical signals between distinct devices, programs, or systems.

interleave. To arrange parts of one sequence of things or events so that they alternate with parts of one or more other sequences of the same nature and so that each sequence retains its identity.

interrupt. (1) A suspension of a process, such as the execution of a computer program, caused by an event external to that process, and performed in such a way that the process can be resumed. (2) In a data transmission, to take an action at a receiving station that causes the transmitting station to terminate a transmission. (3) Synonymous with interruption.

I/O. Input/output.

I/O area. Synonym for buffer.

irrecoverable error. An error that makes recovery impossible without the use of recovery techniques external to the computer program or run.

joystick. In computer graphics, a lever that can pivot in all directions and that is used as a locator device.

k. Prefix kilo; 1000.

K. When referring to storage capacity, 1024. (1024 = 2 to the 10th power.)

Kb. 1024 bytes.

kg. Kilogram; 1000 grams.

kHz. Kilohertz; 1000 hertz.

kilo (k). Prefix 1000

kilogram (kg). 1000 grams.

kilohertz (kHz). 1000 hertz

latch. (1) A simple logic-circuit storage element. (2) A feedback loop in sequential digital circuits used to maintain a state.

least-significant digit. The rightmost digit. See also low-order position.

LED. Light-emitting diode.

light-emitting diode (LED). A semiconductor device that gives off visible or infrared light when activated.

load. In programming, to enter data into storage or working registers.

low power Schottky TTL. A version (LS series) of TTL giving a good compromise between low power and high speed. See also transistor-transistor logic and Schottky TTL.

low-order position. The rightmost position in a string of characters. See also least-significant digit.

m. (1) Prefix milli; 0.001. (2) Meter.

M. (1) Prefix mega; 1 000 000. (2) When referring to computer storage capacity, 1 048 576. (1 048 576 = 2 to the 20th power.)

mA. Milliampere; 0.001 ampere.

machine code. The machine language used for entering text and program instructions onto the recording medium or into storage and which is subsequently used for processing and printout.

machine language. (1) A language that is used directly by a machine. (2) Deprecated term for computer instruction code.

magnetic disk. (1) A flat circular plate with a magnetizable surface layer on which data can be stored by magnetic recording. (2) See also diskette.

main storage. (1) Program-addressable storage from which instructions and other data can be loaded directly into registers for subsequent execution or processing. (2) Contrast with auxiliary storage.

mark. A symbol or symbols that indicate the beginning or the end of a field, of a word, of an item of data, or of a set of data such as a file, a record, or a block.

mask. (1) A pattern of characters that is used to control the retention or elimination of portions of another pattern of characters. (2) To use a pattern of characters to control the retention or elimination of portions of another pattern of characters.

masked. Synonym for disabled.

matrix. (1) A rectangular array of elements, arranged in rows and columns, that may be manipulated according to the rules of matrix algebra. (2) In computers, a logic network in the form of an array of input leads and output leads with logic elements connected at some of their intersections.

matrix printer. A printer in which each character is represented by a pattern of dots; for example, a stylus printer, a wire printer. Synonymous with dot printer.

Mb. 1 048 576 bytes.

mega (M). Prefix 1 000 000.

megahertz (MHz). 1 000 000 hertz.

memory. Term for main storage.

meter (m). A unit of length (equivalent to 39.37 inches).

MFM. Modified frequency modulation.

MHz. Megahertz; 1 000 000 hertz.

micro (μ). Prefix 0.000 001.

microcode. (1) One or more microinstructions. (2) A code, representing the instructions of an instruction set, implemented in a part of storage that is not program-addressable.

microinstruction. (1) An instruction of microcode. (2) A basic or elementary machine instruction.

microprocessor. An integrated circuit that accepts coded instructions for execution; the instructions may be entered, integrated, or stored internally.

microsecond (μ s). 0.000 001 second.

milli (m). Prefix 0.001.

milliampere (mA). 0.001 ampere.

millisecond (ms). 0.001 second.

mnemonic. A symbol chosen to assist the human memory; for example, an abbreviation such as "mpy" for "multiply".

mode. (1) A method of operation; for example, the binary mode, the interpretive mode, the alphanumeric mode. (2) The most frequent value in the statistical sense.

modem (modulator-demodulator). A device that converts serial (bit by bit) digital signals from a business machine (or data

communication equipment) to analog signals that are suitable for transmission in a telephone network. The inverse function is also performed by the modem on reception of analog signals.

modified frequency modulation (MFM). The process of varying the amplitude and frequency of the 'write' signal. MFM pertains to the number of bytes of storage that can be stored on the recording media. The number of bytes is twice the number contained in the same unit area of recording media at single density.

modulation. The process by which some characteristic of one wave (usually high frequency) is varied in accordance with another wave or signal (usually low frequency). This technique is used in modems to make business-machine signals compatible with communication facilities.

modulation rate. The reciprocal of the measure of the shortest nominal time interval between successive significant instants of the modulated signal. If this measure is expressed in seconds, the modulation rate is expressed in baud.

module. (1) A program unit that is discrete and identifiable with respect to compiling, combining with other units, and loading. (2) A packaged functional hardware unit designed for use with other components.

modulo check. A calculation performed on values entered into a system. This calculation is designed to detect errors.

monitor. (1) A device that observes and verifies the operation of a data processing system and indicates any significant departure from the norm. (2) Software or hardware that observes, supervises, controls, or verifies the operations of a system.

most-significant digit. The leftmost (non-zero) digit. See also high-order position.

ms. Millisecond; 0.001 second.

multiplexer. A device capable of interleaving the events of two or more activities, or capable of distributing the events of an interleaved sequence to the respective activities.

multiprogramming. (1) Pertaining to the concurrent execution of two or more computer programs by a computer. (2) A mode of operation that provides for the interleaved execution of two or more computer programs by a single processor.

n. Prefix nano; 0.000 000 001.

NAND. A logic operator having the property that if P is a statement, Q is a statement, R is a statement,..., then the NAND of P, Q, R,... is true if at least one statement is false, false if all statements are true.

NAND gate. A gate in which the output is 0 only if all inputs are 1.

nano (n). Prefix 0.000 000 001.

nanosecond (ns). 0.000 000 001 second.

negative true. Synonym for active low.

negative-going edge. The edge of a pulse or signal changing in a negative direction. Synonymous with falling edge.

non-return-to-zero change-on-ones recording (NRZI). A transmission encoding method in which the data terminal equipment changes the signal to the opposite state to send a binary 1 and leaves it in the same state to send a binary 0.

non-return-to-zero (inverted) recording (NRZI). Deprecated term for non-return-to-zero change-on-ones recording.

NOR. A logic operator having the property that if P is a statement, Q is a statement, R is a statement,..., then the NOR of P, Q, R,... is true if all statements are false, false if at least one statement is true.

NOR gate. A gate in which the output is 0 only if at least one input is 1.

NOT. A logical operator having the property that if P is a statement, then the NOT of P is true if P is false, false if P is true.

NRZI. Non-return-to-zero change-on-ones recording.

ns. Nanosecond; 0.000 000 001 second.

NUL. The null character.

null character (NUL). A control character that is used to accomplish media-fill or time-fill, and that may be inserted into or removed from, a sequence of characters without affecting the meaning of the sequence; however, the control of the equipment or the format may be affected by this character.

odd-even check. Synonym for parity check.

offline. Pertaining to the operation of a functional unit without the continual control of a computer.

one-shot. A circuit that delivers one output pulse of desired duration for each input (trigger) pulse.

open circuit. (1) A discontinuous circuit; that is, one that is broken at one or more points and, consequently, cannot conduct current. Contrast with closed circuit. (2) Pertaining to a no-load condition; for example, the open-circuit voltage of a power supply.

open collector. A switching transistor without an internal connection between its collector and the voltage supply. A connection from the collector to the voltage supply is made through an external (pull-up) resistor.

operand. (1) An entity to which an operation is applied. (2) That which is operated upon. An operand is usually identified by an address part of an instruction.

operating system. Software that controls the execution of programs; an operating system may provide services such as resource allocation, scheduling, input/output control, and data management.

OR. A logic operator having the property that if P is a statement, Q is a statement, R is a statement,..., then the OR of P, Q, R,...is true if at least one statement is true, false if all statements are false.

OR gate. A gate in which the output is 1 only if at least one input is 1.

output. Pertaining to a device, process, or channel involved in an output process, or to the data or states involved in an output process.

output process. (1) The process that consists of the delivery of data from a data processing system, or from any part of it. (2) The return of information from a data processing system to an end user, including the translation of data from a machine language to a language that the end user can understand.

overcurrent. A current of higher than specified strength.

overflow indicator. (1) An indicator that signifies when the last line on a page has been printed or passed. (2) An indicator that is set on if the result of an arithmetic operation exceeds the capacity of the accumulator.

overrun. Loss of data because a receiving device is unable to accept data at the rate it is transmitted.

overvoltage. A voltage of higher than specified value.

parallel. (1) Pertaining to the concurrent or simultaneous operation of two or more devices, or to the concurrent performance of two or more activities. (2) Pertaining to the concurrent or simultaneous occurrence of two or more related activities in multiple devices or channels. (3) Pertaining to the

simultaneity of two or more processes. (4) Pertaining to the simultaneous processing of the individual parts of a whole, such as the bits of a character and the characters of a word, using separate facilities for the various parts. (5) Contrast with serial.

parameter. (1) A variable that is given a constant value for a specified application and that may denote the application. (2) A name in a procedure that is used to refer to an argument passed to that procedure.

parity bit. A binary digit appended to a group of binary digits to make the sum of all the digits either always odd (odd parity) or always even (even parity).

parity check. (1) A redundancy check that uses a parity bit. (2) Synonymous with odd-even check.

PEL. Picture element.

personal computer. A small home or business computer that has a processor and keyboard and that can be connected to a television or some other monitor. An optional printer is usually available.

phototransistor. A transistor whose switching action is controlled by light shining on it.

picture element (PEL). The smallest displayable unit on a display.

polling. (1) Interrogation of devices for purposes such as to avoid contention, to determine operational status, or to determine readiness to send or receive data. (2) The process whereby stations are invited, one at a time, to transmit.

port. An access point for data entry or exit.

positive true. Synonym for active high.

positive-going edge. The edge of a pulse or signal changing in a positive direction. Synonymous with rising edge.

potentiometer. A variable resistor with three terminals, one at each end and one on a slider (wiper).

power supply. A device that produces the power needed to operate electronic equipment.

printed circuit. A pattern of conductors (corresponding to the wiring of an electronic circuit) formed on a board of insulating material.

printed-circuit board. A usually copper-clad plastic board used to make a printed circuit.

priority. A rank assigned to a task that determines its precedence in receiving system resources.

processing program. A program that performs such functions as compiling, assembling, or translating for a particular programming language.

processing unit. A functional unit that consists of one or more processors and all or part of internal storage.

processor. (1) In a computer, a functional unit that interprets and executes instructions. (2) A functional unit, a part of another unit such as a terminal or a processing unit, that interprets and executes instructions. (3) Deprecated term for processing program. (4) See microprocessor.

program. (1) A series of actions designed to achieve a certain result. (2) A series of instructions telling the computer how to handle a problem or task. (3) To design, write, and test computer programs.

programmable read-only memory (PROM). A read-only memory that can be programmed by the user.

programming language. (1) An artificial language established for expressing computer programs. (2) A set of characters and rules with meanings assigned prior to their use, for writing computer programs.

programming system. One or more programming languages and the necessary software for using these languages with particular automatic data-processing equipment.

PROM. Programmable read-only memory.

propagation delay. (1) The time necessary for a signal to travel from one point on a circuit to another. (2) The time delay between a signal change at an input and the corresponding change at an output.

protocol. (1) A specification for the format and relative timing of information exchanged between communicating parties. (2) The set of rules governing the operation of functional units of a communication system that must be followed if communication is to be achieved.

pulse. A variation in the value of a quantity, short in relation to the time schedule of interest, the final value being the same as the initial value.

radio frequency (RF). An ac frequency that is higher than the highest audio frequency. So called because of the application to radio communication.

radix. (1) In a radix numeration system, the positive integer by which the weight of the digit place is multiplied to obtain the weight of the digit place with the next higher weight; for example, in the decimal numeration system the radix of each digit place is 10. (2) Another term for base.

radix numeration system. A positional representation system in which the ratio of the weight of any one digit place to the weight of the digit place with the next lower weight is a positive integer (the radix). The permissible values of the character in any digit place range from 0 to one less than the radix.

RAM. Random access memory. Read/write memory.

random access memory (RAM). Read/write memory.

RAS. In the IBM Personal Computer, row address strobe.

raster. In computer graphics, a predetermined pattern of lines that provides uniform coverage of a display space.

read. To acquire or interpret data from a storage device, from a data medium, or from another source.

read-only memory (ROM). A storage device whose contents cannot be modified. The memory is retained when power is removed.

read/write memory. A storage device whose contents can be modified. Also called RAM.

recoverable error. An error condition that allows continued execution of a program.

red-green-blue-intensity (RGBI). The description of a direct-drive color monitor that accepts input signals of red, green, blue, and intensity.

redundancy check. A check that depends on extra characters attached to data for the detection of errors. See cyclic redundancy check.

register. (1) A storage device, having a specified storage capacity such as a bit, a byte, or a computer word, and usually intended for a special purpose. (2) A storage device in which specific data is stored.

retry. To resend the current block of data (from the last EOB or ETB) a prescribed number of times, or until it is entered correctly or accepted.

reverse video. A form of highlighting a character, field, or cursor by reversing the color of the character, field, or cursor with its background; for example, changing a red character on a black background to a black character on a red background.

RF. Radio frequency.

RF modulator. The device used to convert the composite video signal to the antenna level input of a home TV.

RGBI. Red-green-blue-intensity.

rising edge. Synonym for positive-going edge.

ROM. Read-only memory.

ROM/BIOS. The ROM resident basic input/output system, which provides the level control of the major I/O devices in the computer system.

row address strobe (RAS). A signal that latches the row address in a memory chip.

RS-232C. A standard by the EIA for communication between computers and external equipment.

RTS. Request to send. Associated with modem control.

run. A single continuous performance of a computer program or routine.

schematic. The representation, usually in a drawing or diagram form, of a logical or physical structure.

Schottky TTL. A version (S series) of TTL with faster switching speed, but requiring more power. See also transistor-transistor logic and low power Schottky TTL.

SDLC. Synchronous Data Link Control

sector. That part of a track or band on a magnetic drum, a magnetic disk, or a disk pack that can be accessed by the magnetic heads in the course of a predetermined rotational displacement of the particular device.

SERDES. Serializer/deserializer.

serial. (1) Pertaining to the sequential performance of two or more activities in a single device. In English, the modifiers serial and parallel usually refer to devices, as opposed to sequential and consecutive, which refer to processes. (2) Pertaining to the sequential or consecutive occurrence of two or more related activities in a single device or channel. (3) Pertaining to the sequential processing of the individual parts of a whole, such as the bits of a character or the characters of a word, using the same facilities for successive parts. (4) Contrast with parallel.

serializer/deserializer (SERDES). A device that serializes output from, and deserializes input to, a business machine.

setup. (1) In a computer that consists of an assembly of individual computing units, the arrangement of interconnections between the units, and the adjustments needed for the computer to operate. (2) The preparation of a computing system to perform a job or job step. Setup is usually performed by an operator and often involves performing routine functions, such as mounting tape reels. (3) The preparation of the system for normal operation.

short circuit. A low-resistance path through which current flows, rather than through a component or circuit.

signal. A variation of a physical quantity, used to convey data.

sink. A device or circuit into which current drains.

software. (1) Computer programs, procedures, and rules concerned with the operation of a data processing system. (2) Contrast with hardware.

source. The origin of a signal or electrical energy.

square wave. An alternating or pulsating current or voltage whose waveshape is square.

square wave generator. A signal generator delivering an output signal having a square waveform.

SS. Start-stop.

start bit. (1) A signal to a receiving mechanism to get ready to receive data or perform a function. (2) In a start-stop system, a signal preceding a character or block that prepares the receiving device for the reception of the code elements.

start-of-text (STX). A transmission control character that precedes a text and may be used to terminate the message heading.

start-stop system. A data transmission system in which each character is preceded by a start bit and is followed by a stop bit.

start-stop (SS) transmission. (1) Asynchronous transmission such that a group of signals representing a character is preceded by a start bit and followed by a stop bit. (2) Asynchronous transmission in which a group of bits is preceded by a start bit that prepares the receiving mechanism for the reception and registration of a character and is followed by at least one stop bit that enables the receiving mechanism to come to an idle condition pending the reception of the next character.

static memory. RAM using flip-flops as the memory elements. Data is retained as long as power is applied to the flip-flops. Contrast with dynamic memory.

stop bit. (1) A signal to a receiving mechanism to wait for the next signal. (2) In a start-stop system, a signal following a character or block that prepares the receiving device for the reception of a subsequent character or block.

storage. (1) A storage device. (2) A device, or part of a device, that can retain data. (3) The retention of data in a storage device. (4) The placement of data into a storage device.

strobe. An instrument that emits adjustable-rate flashes of light. Used to measure the speed of rotating or vibrating objects.

STX. Start-of-text.

symbol. (1) A conventional representation of a concept. (2) A representation of something by reason of relationship, association, or convention.

synchronization. The process of adjusting the corresponding significant instants of two signals to obtain the desired phase relationship between these instants.

Synchronous Data Link Control (SDLC). A protocol for management of data transfer over a data link.

synchronous transmission. (1) Data transmission in which the time of occurrence of each signal representing a bit is related to a fixed time frame. (2) Data transmission in which the sending and receiving devices are operating continuously at substantially the same frequency and are maintained, by means of correction, in a desired phase relationship.

syntax. (1) The relationship among characters or groups of characters, independent of their meanings or the manner of their interpretation and use. (2) The structure of expressions in a language. (3) The rules governing the structure of a language. (4) The relationships among symbols.

text. In ASCII and data communication, a sequence of characters treated as an entity if preceded and terminated by one STX and one ETX transmission control character, respectively.

time-out. (1) A parameter related to an enforced event designed to occur at the conclusion of a predetermined elapsed time. A time-out condition can be cancelled by the receipt of an appropriate time-out cancellation signal. (2) A time interval

allotted for certain operations to occur; for example, response to polling or addressing before system operation is interrupted and must be restarted.

track. (1) The path or one of the set of paths, parallel to the reference edge on a data medium, associated with a single reading or writing component as the data medium moves past the component. (2) The portion of a moving data medium such as a drum, or disk, that is accessible to a given reading head position.

transistor-transistor logic (TTL). A popular logic circuit family that uses multiple-emitter transistors.

translate. To transform data from one language to another.

transmission. (1) The sending of data from one place for reception elsewhere. (2) In ASCII and data communication, a series of characters including headings and text. (3) The dispatching of a signal, message, or other form of intelligence by wire, radio, telephone, or other means. (4) One or more blocks or messages. For BSC and start-stop devices, a transmission is terminated by an EOT character. (5) Synonymous with data transmission.

TTL. Transistor-transistor logic.

V. Volt.

video. Computer data or graphics displayed on a cathode ray tube, monitor, or display.

volt. The basic practical unit of electric pressure. The potential that causes electrons to flow through a circuit.

W. Watt.

watt. The practical unit of electric power.

word. (1) A character string or a bit string considered as an entity. (2) See computer word.

write. To make a permanent or transient recording of data in a storage device or on a data medium.

write precompensation. The varying of the timing of the head current from the outer tracks to the inner tracks of the diskette to keep a constant 'write' signal.
