ZURN® Control-Flo . . . Today's Successful Answer to More

THE ZURN "CONTROL-FLO CONCEPT"

Originally, Zurn introduced the scientifically- advanced "Control-Flo" drainage principle for dead-level roofs. Today, after thousands of successful applications in modern, large dead-level roof areas, Zurn engineers have adapted the comprehensive "Control-Flo" data to **sloped roof** areas.

WHAT IS "CONTROL-FLO"?

It is an advanced method of removing rain water off dead-level or sloped roofs. As contrasted with conventional drainage practices, which attempt to drain off storm water as quickly as it falls on the roof's surface, "Control- Flo" drains the roof at a controlled rate. Excess water accumulates on the roof under controlled conditions... then drains off at a lower rate after a storm abates.

CUTS DRAINAGE COSTS

Fewer roof drains, smaller diameter piping, smaller sewer sizes, and lower installation costs are possible with a "Control-Flo" drainage system because roof areas are utilized as temporary storage reservoirs.

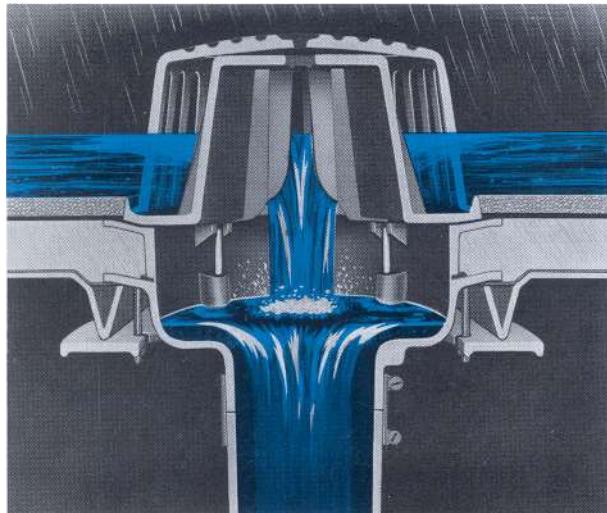

REDUCES PROBABILITY OF STORM DAMAGE

Lightens load on combination sewers by reducing rate of water drain from roof tops during severe storms thereby reducing probability of flooded sewers, and consequent backflow into basements and other low areas.

THANKS TO EXCLUSIVE ZURN

"AQUA-WEIR" ACTION

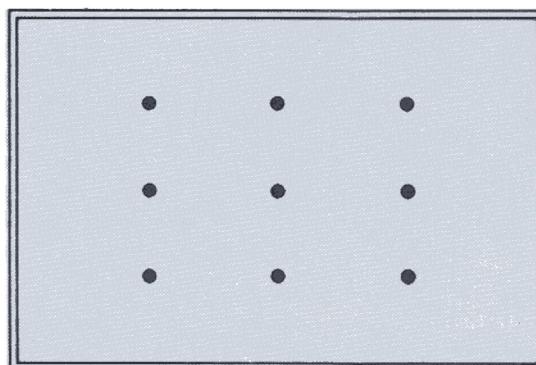

Key to successful "Control-Flo" drainage is a unique, scientifically-designed weir containing accurately calibrated notches with sides formed by parabolic curves which provide flow rates directly proportional to the head. Shape and size of notches are based on pre- determined flow rates, and all factors involved in roof drainage to assure permanent regulation of drainage flow rates for specific geographic locations and rainfall intensities.

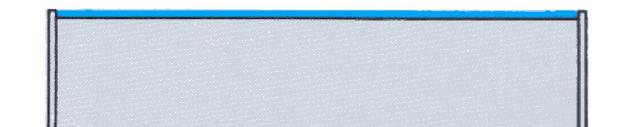

DEFINITION

DEAD LEVEL ROOFS

A dead-level roof for purposes of applying the Zurn "Control-Flo" drainage principle is one which has been designed for zero slope across its entire surface.

(Plan View)

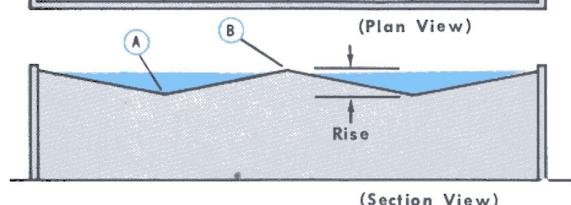

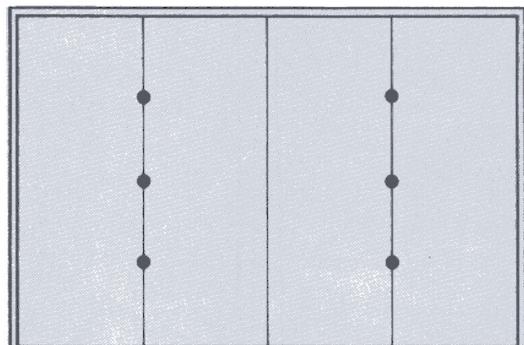

(Section View)

SLOPED ROOFS

A sloped roof is one designed commonly with a shallow slope. The Zurn "Control-Flo" drainage system can be applied to any slope which results in a total rise up to 6"... and data can be calculated for rises exceeding 6".

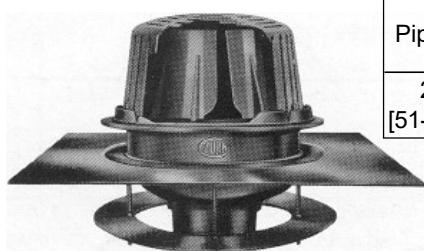

The total rise of a roof as calculated for "Control-Flo" application is defined as the vertical increase in height in inches, from the low point or valley of a sloping roof (A) to the top of the sloping section (B). (Example: a roof that slopes 1/8" per foot having a 24-foot span would have a rise of 24 x 1/8 or 3")

Economical Roof Drainage Installation

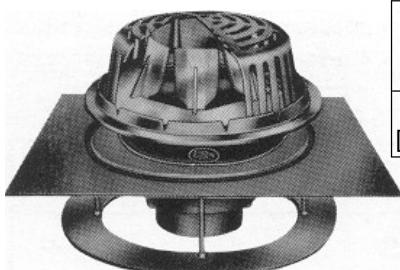

SPECIFICATION DATA

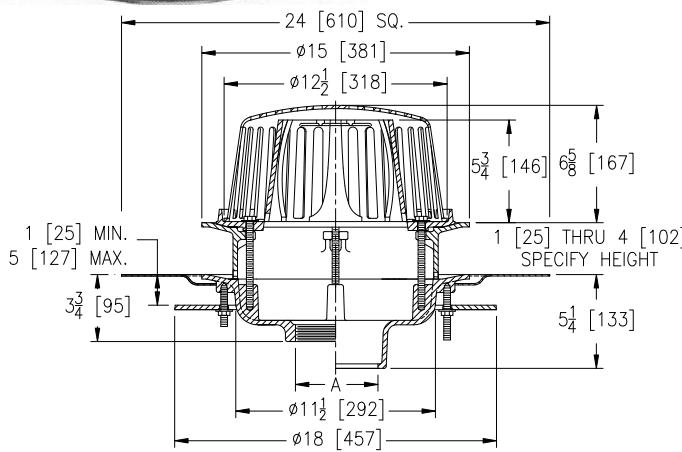

A Pipe Size	Approx. Wt. Lbs. [kg]	Dome Open Area Sq. In. [cm ²]
2-3-4 [51-76-102]	56 [25]	103 [665]

ENGINEERING SPECIFICATION: ZURN Z105-C-E-R 15" Diameter "Control-Flo" roof drain for dead-level roof construction, Dura-Coated cast iron body, "Control-Flo" weir shall be linear functioning with integral membrane flashing clamp/gravel guard, static extension, secondary clamping collar with O-ring, Poly-Dome, roof sump receiver and underdeck clamp. All data shall be verified proportional to flow rates.

A Pipe Size	Approx. Wt. Lbs. [kg]	Dome Open Area Sq. In. [cm ²]
2-3-4 [51-76-102]	60 [27]	148 [955]

ENGINEERING SPECIFICATION: ZURN Z105-C-E-R-10 "Control-Flo" roof drain for Sloped Roof construction, Dura-Coated cast iron body, "Control-Flo" weir shall be linear functioning with integral membrane flashing clamp/gravel guard and 6 5/8 [168] high Aluminum dome. All data shall be verified proportional to flow rates.

ROOF DESIGN RECOMMENDATIONS

Basic roofing design should incorporate protection that will prevent roof overloading by installing adequate overflow scuppers in parapet walls.

GENERAL RECOMMENDATIONS

On dead-level roofs, our general recommendations are to design for a 3" depth for the 10-year storm. In this case, even the 100-year storm will not result in a maximum depth of 6". A 6" depth represents a roof load of 31.2 pounds per square foot which approximates the 30 pound per square foot factor commonly used in roof design.

NOTE: A more conservative practice used by a few engineers in the past, depending upon other design considerations, has been to design for the 3" depth with the 25, 50, or even 100-year storm . . . and to also lower scuppers to 5" or 4" above roof level. In either case, the final determination rests with the engineering personnel responsible for this phase of the design.

GENERAL RECOMMENDATIONS

On sloping roofs, we again recommend a 3" design depth for the 10-year storm, but by 3" we refer to an equivalent depth of 3". An equivalent depth is the depth of water attained at the drains that results in the same roof stresses as those realized on a dead-level roof. In all cases this equivalent depth is almost equal to that attained by using the same notch area rating for the different rises to 6". With the same depth of water at the drain the roof stresses will decrease with increasing total rise. Therefore, it would be possible to have a depth in excess of 6" at the drain on a sloping roof without exceeding stresses normally encountered in a 6" depth on a dead-level roof. However, it is recommended that scuppers be placed to limit the maximum water depth on any roof to 6" to prevent the over flow of the weirs on the drains and consequent overloading of drain piping.

NOTE: An equivalent depth is that depth of water attained at the drains at the lowest line or valley of the roof with all other conditions such as notch area and rainfall intensity being equal. For Galveston, Texas a notch area of 1800 square feet results in a 3" depth on a **dead-level** roof for a 10-year storm. For the same notch area and a 10-year storm, equivalent depths for a 2", 4", and 6" rise respectively on a **sloped roof** would be 3.4", 3.8", and 4.6". Roof stresses will be approximately equal in all cases.

Control-Flo Drain Selection is Quick and Easy . . .

The exclusive Zurn "Selecta-Drain". Chart (pages 6, 7, 8, 9) tabulates recommended selection data for several hundred localities in the United States. It constitutes your best assurance of sure, safe, economical additional data for your Zurn "Control-Flo" systems for your specific geographical area.

If the "Selecta-Drain" Chart doesn't not suit your specific design criteria, write directly to Zurn Industries, Inc. Field Service Engineering, Specification Drainage Operations, Erie, Pa for additional date for your locality. Listed below is additional information pertinent to proper engineering of the "Control-Flo" system.

ROOF USED AS TEMPORARY RETENTION

The key to economical "Control-Flo" drainage is the utilization of large roof areas to temporarily store the maximum amount of water without overloading average roofs or creating excessive drain down time during periods of heavy rainfall.

The data shown in the "Selecta-Drain" Chart, which takes all these factors into consideration, represents only one point on a series of curves prepared for each locality and was determined after careful study and research as imparting optimum economy in design.

ROOF LOADING AND RUN-OFF RATES

The values for notch areas selected from the design curves were based on a 3" head on a dead-level roof for the 10-year storm. In low rainfall localities the area per notch was limited to 25,000 square feet to keep the drain down time within reasonable limits. The same area for each respective locality was used for the various roof rises for sloping roofs.

Extensive studies show that stresses due to water load on a sloping roof for any fixed set of conditions are very nearly the same as those on a dead-level roof. A sloping roof tends to concentrate more water in the valleys and increase the water depth at this point. The greater depth around the drain leads to a faster run-off rate, particularly a faster early run-off rate. As a result, the total volume of water stored on the roof is less, and the total load on the sloping roof is less. By using the same area on the sloping roof as on the dead-level roof the increase in roof stresses due to increased water depth in the valleys is offset by the decrease in the total load due to less water stored. The net result is the maximum roof stresses are approximately the same for single span, rise and fixed set of conditions. A fixed set of conditions would be the same notch area, the same frequency storm, and the same locality.

NOTCH FLOW AND WATER DEPTH

The flow through each notch of the "Control-Flo" weir is 10 GPM per inch of head. To compute the depth of water in inches at the drain, obtain the total flow for any fixed set of conditions and locale from the "Selecta-Drain" Chart and divide by 10. For example, for Anniston, Alabama the discharge rates are 30, 35, 39 and 43 GPM for the 10, 25, 50 and 100-year storms respectively on a dead-level roof.

Since the possibility of exceeding 4.3" of water exists only once every 100 years, the drains can be sized to carry 43 GPM per notch and scuppers can be set at a height of 4.3" above the roof to prevent overloading the drains if a worse than 100-year storm occurs. On a similar basis, drain pipe sizes and scupper heights can be selected for various roof slopes and storm frequencies.

ADDITIONAL NOTCH RATINGS

The "Selecta-Drain" Chart along with Tables I and II enables the engineer to select "Control-Flo" Drains and drain pipe sizes for most applications. The "Selecta-Drain" Chart and Tables I and II are computed for a proportional flow weir that is sized to give a flow of 10 GPM per inch of head. However, this data can be applied to other sizes of proportional flow weirs by simple multiplication or division. For example, if a similar weir that is sized to give a flow of 5 GPM per inch is substituted for the 10 GPM per inch weir, the notch area and discharge in GPM would be divided by two, and this opening would be given a 7'2 notch area rating.

PROPER DRAIN LOCATION

The following good design practice is recommended for selecting the proper number of "Control-Flo" drains for a given area.

On dead-level roofs, drains should be located no further than 50 feet from each edge of the roof to assure good run-off regardless of wind direction. Weir should be flush with roof surface, not recessed.

On sloping roofs, drains should be located in the valleys at a distance no greater than 50 feet from each end of the valleys. Weir should be flush with the valley roof surface, not recessed.

On large roof areas, drains should not be spaced at a distance greater than 200 feet.

Saves Specification Time, Assures Proper Application

QUICK EASY SELECTION

Using the "Selecta-Drain" Chart (pages 6, 7, 8, 9) in combination with the steps and examples appearing below, should save you countless hours in engineering specification time. This vast compilation of data is related to the proper selection of drains for over 200 cities. If a specific city does not appear in this tabulation, choose the city, nearest your area and select the proper drain using these factors.

3 EASY STEPS

AND 3 TYPICAL EXAMPLES FOR APPLICATION OF SURE, SCIENTIFIC CONTROL OF DRAINAGE FROM DEAD-LEVEL AND SLOPING ROOFS WITH THE ZURN CONCEPT

WASHINGTON, D. C.	DEAD-LEVEL ROOF	4 INCH RISE	6 INCH RISE
1 Determine total roof area or individual areas when roof is divided by expansion joints or peaks in the case of sloping roof.	Roof Area: 192 ft. x 500 ft. = 96,000 sq. ft.	3 Individual Roof Areas: 64 ft. x 500 ft. = 32,000 sq. ft. Valleys 500 ft. long $3 \times 32,000 = 96,000$ sq. ft.	2 Individual Roof Areas: 98 ft. x 500 ft. = 48,000 sq. ft. Valleys 500 ft. long $2 \times 48,000 = 96,000$ sq. ft.
2 Divide roof area or individual areas by Zurn Notch Area Rating to obtain the total number of notches required.	Zurn Notch Area Rating for Washington, D. C. = 13,300 "Selecta-Drain" Chart Total Notches Required = 96,000 sq. ft. 13,300 sq. ft. notch area = 7.2 notches - USE 8 PER AREA	Zurn Notch Area Rating for Washington, D.C. = 13,000 from "Selecta-Drain" Chart Total Notches Required = 32,000 sq. ft. 13,300 sq. ft. notch area = 2.4 notches - USE 8 PER AREA	Zurn Notch Area Rating for Washington, D.C. = 13,000 from "Selecta-Drain" Chart Total Notches Required = 48,000 sq. ft. 13,300 sq. ft. notch area = 3.6 notches - USE 4 PER AREA
3 Determine total number of drains required by not exceeding maximum spacing dimensions in the preceding instructions. Divide total number of notches required to determine the number of notches per drain. Note flow rate for the 100-year storm and divide by 10 to determine maximum water depth at drain and use this dimension to determine scupper height. Maximum scupper height to be used is 6". Use this flowrate to size leaders and drain lines.	6 drains required. 3 along each side within 50 ft. of the side with a spacing of 50 ft. - 200 ft. 200 ft. - 50 ft. Two drains must have two notches for a total of eight notches. Located at diagonally opposite corners. Flow rate for the 100-year storm is 44 GPM. Maximum water depth and scupper height equals 4.4". Size leaders from single notch drains for 44 GPM and leaders from double notch drains for 88 GPM.	3 drains per area required in the valleys 50 ft. from each end with one in the middle. All drains will have one notch. Flow rate for the 100-year storm is 59 GPM maximum. Water depth and scupper height equals 5.9". Size leaders for 59 GPM.	3 drains per area required in the valleys 50 ft. from each end with one in the middle. 4 notches are required therefore one drain must have two notches. Locate this one in the middle. Flow rate for the 100-year storm is 64 GPM. Locate scuppers at 6" and use 60 GPM as maximum flow rate and 6" maximum depth. The probability of water flowing out suppers is now less than once every 50 years instead of every 100 years. Size leaders for 60 GPM

SPECIAL CONSIDERATIONS

The 3" design water level for the 10-year storm represents a roof load of approximately 15 lbs. per sq. ft. This is only half the usual minimum design roof load rating of 30 lbs. per sq. ft. and so presents no problem from that aspect. However, since it is desirable to contain the design depth of water on the roof and to prevent spillage over the roof in high wind condition, it is recommended that any roof construction, parapets, flashing and curves should be high enough to prevent flooding over them.

Another special case applies to water cooled roofs and here the "Control-Flo" principle can still be used. An adjustable collar on the drain body will retain a pool of water 0 to 3" deep on the roof and a 3" high "Control-Flo" Weir on top of the adjustable collar will control storm water falling on this pool. This restricts maximum depth on the roof to 6" and scuppers should be located at this height. Since the weirs are only 3" high on this drain, they should be selected for a 3" head based on the 100-year frequency storm.

Select Proper Vertical Storm Drain Piping

Roof Drainage Data

While the flow rate for any design condition can be easily computed from the data contained on the preceding pages, the tabulations shown below (and on page 14) can be used to simplify selection of drain line sizes.

TABLE I - Suggested Relation of Drain Outlet and Vertical Leader Size to of the six Z105-10 Zum Control-Flo Roof Drains (Based on National Plumbing Code ASA-A40.8 Data on Vertical Leaders).

No. of Notches in Drain	Max. Flow per Notch in GPM				
	Pipe Size				
	2	3	4	5	
1	30	60*	-	-	
2	15	45	60*	-	
3	-	31	60*	-	
4	-	23	48	60*	
5	-	18	38	60*	
6	-	15	32	60*	

* Maximum flow obtainable from 1 notch.

Table I illustrates gallons per minute from each notch of the six Z105-10 drains that can be carried off by various leader sizes. Once the drains are selected for a given roof per this manual, simply read the GPM flow per notch from the chart, refer to **Table I** and select the smallest drain line that will accommodate that flow. Drain pipes should be sized for the 100-year storm unless scuppers are located at a height that will not permit a depth of water to accumulate on the roof that is predicted for the 100-year storm. For example, if your installation is Anniston, Alabama, on a dead-level roof the data for the 100-year storm shows a discharge of 43 GPM per notch. For this application scuppers would be located at a 4.3" height. Using Table I a 3" drain pipe or vertical leader would be used for a drain with 1- or 2-notches. A 4" leader would be used with a 3- or 4-notch drain and a 5" leader with a 5- or 6-notch drain. For Anniston, Alabama, and a roof with a 2" rise, the 100-year storm shows a flow rate of 50 GPM. In this case scuppers should be located at a height of 5.0". A 3" leader would be used with a single notch drain, a 4" leader with a 2- and 3-notch drain, and a 5" leader with a 4-, 5- or 6-notch drain. The same type of selection would be made for a roof with a 4" rise. For Anniston, Alabama, the flow rate for the 100-year storm would be located at a height of 5.9".

For the roof with a 6" rise, the data for Anniston, Alabama, as well as several other localities, for the 100-year storm, shows a flow rate greater than 60 GPM. In these cases the scuppers will be located at the maximum recommended height of 6" and the vertical leaders will be sized for a maximum flow rate of 60 GPM per notch.

In the few cases where the data shows a flow rate in excess of 60 GPM for the 100-year storm, and if all drains and drain lines are sized according to recommendations, the only consequence will be a brief flow through the scuppers more often than once every 100 years.

Select Proper Horizontal Storm Drain Piping

Table II is similar to **Table I** but is used in determining the size of the building storm drain. Use the same flow rate established for sizing the vertical leaders to size the storm drain. Count the total number of notches feeding any one drain or branch to the drain. Enter the Table at the total number of notches and under the proper storm drain slope select the column that gives a flow rate equal to or larger than the established notch flow rate. Read the storm drain size required at the top of this column.

TABLE II - Suggested Relation of Horizontal Storm Drain Size to Zurn Control-Flo Roof Drainage (Based on National Plumbing Code ASA-A40.8 Data on Horizontal Storm Drains w/ 1/8", 1/4" and 1/2" per foot slope).

Total No. of Notches Discharging to Storm Drain	MAX. FLOW PER NOTCH IN GPM							MAX. FLOW PER NOTCH IN GPM							MAX. FLOW PER NOTCH IN GPM											
	Storm Drain Size 1/8" per ft. slope							Storm Drain Size 1/4" per ft. slope							Storm Drain Size 1/2" per ft. slope

Special Considerations for Structural Safety Rigid Roof Design

Normal Practice of Roof Design is Based on 30-lbs. Per Sq. Ft. ... therefore this factor should definitely be kept in mind as a prime requirement for assuring a structurally sound roof. Otherwise, roof deflection may minimize the advantages of a well-designed roof drainage system.

Failure to recognize the adverse effects of roof deflection, even with conventional roof drainage, may lead to roof failure. With the new concept of "Control-Flo" Roof Drainage, the design condition of deflection is equally important. If severe deflection is permitted, rain water will simply seek low areas, thus intensifying the degree of deflection. Thus it is extremely important that flat roofs are designed in accordance with normal load factors so that deflection will be slight enough in any bay to prevent progressive deflection which could cause water depths to load the roof beyond its design limits.

SCUPPERS AND OVERFLOW DRAINS

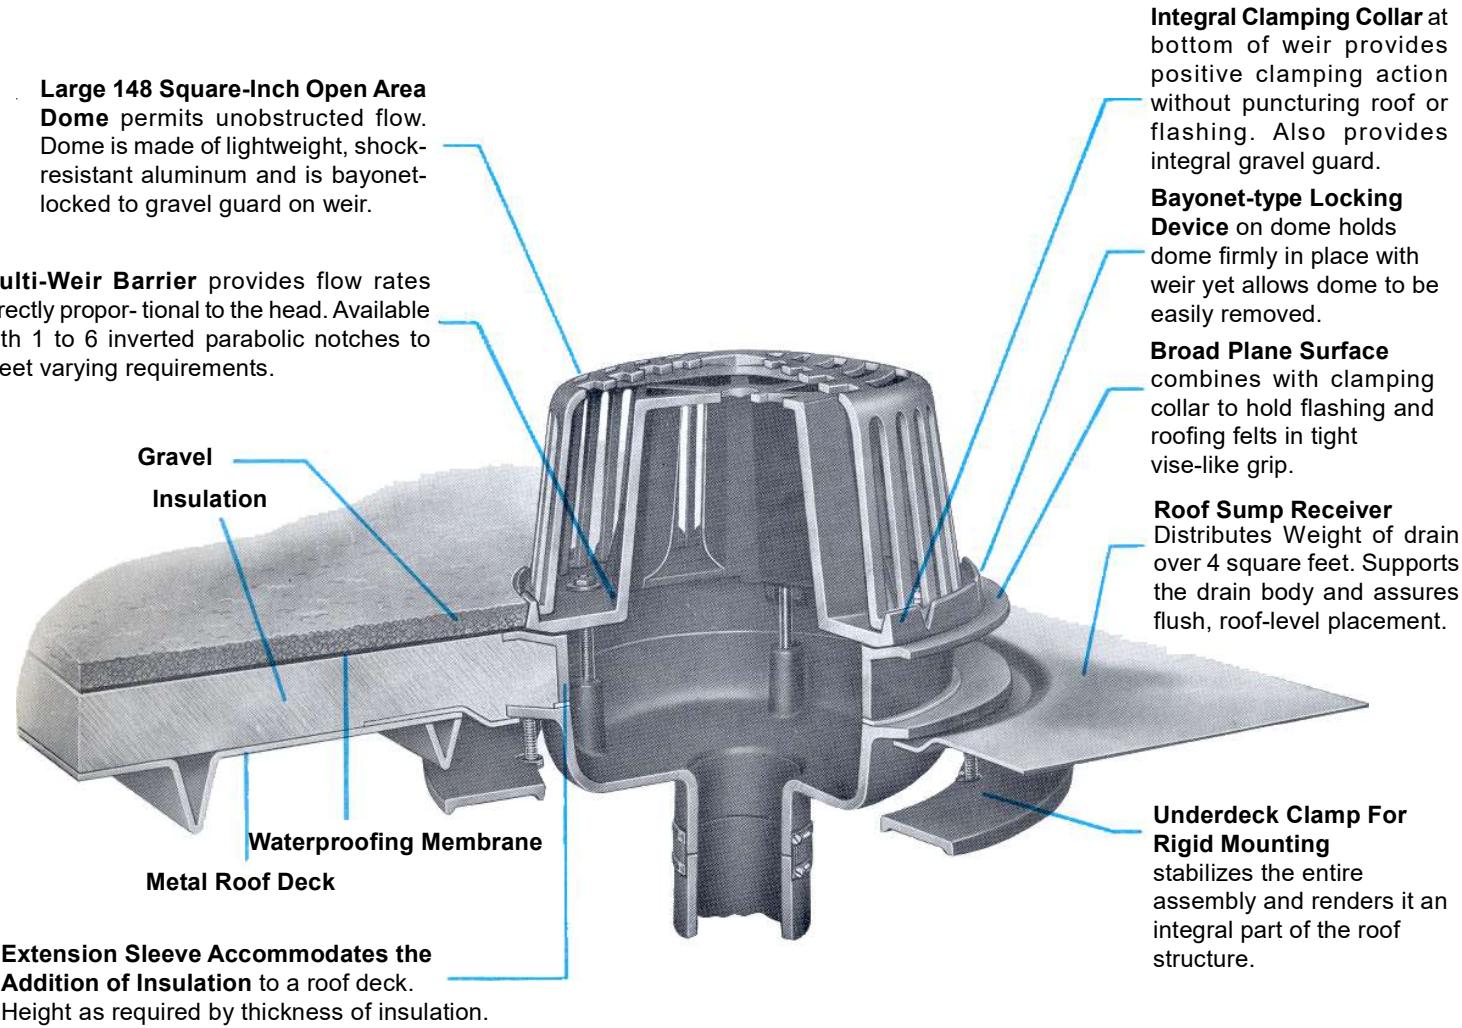

Roofing members and understructures, weakened by seepage and rot resulting from improper drainage and roof construction can give away under the weight of rapidly accumulated water during flash storms. Thus, it is recommended, and often required by building codes, to install scuppers and overflow drains in parapet-type roofs. Properly selected and sized scuppers and overflow drains are vital to a well-engineered drainage system to prevent excessive loading, erosion, seepage and rotting.

Control-Flo Roof Drains

the most advanced drainage control available,
lets you design roof drainage systems with confidence
